Mr. Ehricke. That is possible, sir. One can use a technique that is known, in interceptor development as proportionate navigation. In other words, you lock onto the station, like you would intercept it with a hostile intent, only in this case you do not really intercept it, you get close to it.

When people are up there, they will send a beam and guide you in like an all-weather system guides you into an airport.

Mr. McDonough. This whole mass, all the equipment and the man you have the model of, are traveling at what speed?

Mr. Ehricke. At an approximately 17,500 miles per hour. It is not exactly any more than 18,000, it is a little bit slower.

Mr. McDonough. The man does not feel the speed?

Mr. Ehricke. No, sir. To them they seem to stand still and the earth is slowly rotating underneath.

Mr. Fulton. If there is only 5 miles difference between 2 certain satellites, 5 miles an hour difference, there would only be a bumped fender if they collided, even though they are going each 17,500 miles and 17,505 miles respectively?

Mr. EHRICKE. Yes, sir. This relative difference would be comparatively small and they would be reasonably protected.

After the bubble is installed, itself, you make the necessary connections and interior equipment.

You see here on the outer end where the gravity is highest, you have the sanitary room. That means washroom, and so on.

Way down here you have the collection of waste water from the washroom, as well as from the next floor, the food dispensary.

You see, water is something very heavy and we need it in rather large quantities normally. We cannot afford to carry all that water all the time up, use it and then throw it into space. So we collect it like the famous box in the airplane, but then we go one step further; we boil the whole stuff electrically to evaporate it, it is a distillation process. Then the vapor is being ducted into a condenser system which is regulated by a photosensitive element. So if it points in the sun, it closes. If it points away from the sun, then it opens up and it radiates the heat out.

So out here, the steam condenses into pure water again, clean water. You have the necessary chemical means. This is a technique that is well understood already today. The pure water goes into the water container and can be drawn out again.

Now, nonusable residuals are being flushed by means of air pressure out into space through a special waste-disposal outlet.

Here you have the dispensary and recreation room. Here you have the sleeping room, and up here you have the control room, laboratory communications centers, and so on.

Now, the structure here is not pressurized. So if a meteor goes through, it does not hurt you, there is no air inside. Only this part of the bubble is pressurized. Therefore, you need an air lock here. You close this air lock. For instance, if you want to go out, this would be closed and you would put the necessary air in here, then you open on the inside and go in, close on the inside, pump the air out into this container until it is completely equal and then you open this door and you go out. Then you are out in this house.

You can get out of the house by this manhole here. You can get out and in through this one here. The basket is just for safety reasons.

Way back here you have the odor absorber. You see, you have one other cycle and that is the air cycle. Unlike the water cycle, which brings the water completely back and can be reused, the air cycle is not a closed cycle as far as the oxygen is concerned. But it is a cycle as far as the nitrogen and helium is concerned that you have mixed to your oxygen. Fresh air is being pushed into a fresh air circulatory system. Each cabinet has its own fresh air circulatory system. All these guys are living better than some people on the surface of the earth.

Mr. FORD. Why are they horizontal?

Mr. EHRICKE. The reason is that this station is falling freely, the only weight is due to their rotation. So down is in this direction and up in that direction.

Mr. FULTON. Why do you not put a sky anchor out behind the capsule so that when it is rotated it does not rotate at a focal point within the axis of the capsule but clear out behind, so that you get a more simulated gravity?

Mr. EHRICKE. This could be done. This is principally possible. But in this particular case it was not necessary. We have another design of a more advanced station where this particular hub point is indeed out on a cable.

Mr. McDONOUGH. What is the little screen above the entry point?

Mr. EHRICKE. This is an antenna to maintain connection with the earth.

Then the air is being used up, going back through the cycle. You have CO_2 and so on and various other things, and you get in here first an odor absorber and then a regenerator and purifier. After you have done this, you have clean helium or clean nitrogen again. Then you add from the oxygen. The air is clean, but it is still warm. You cool it by the water content. It will gradually be warmed up again so you have lukewarm water.

Mr. McDONOUGH. You never have more water than you take up, but you lose some?

Mr. EHRICKE. You lose some. You have to supply it from time to time.

Mr. McDONOUGH. You cannnot produce it up there?

Mr. EHRICKE. No.

Mr. McDONOUGH. So far as the interior temperature is concerned, how do you regulate that?

Mr. EHRICKE. The temperature is being regulated by cooling the air. You have a constant air conditioning in your whole system. In other words, the air is never stagnant. It is being softly blown in one end and softly sucked out in the other.

Mr. McDONOUGH. Are there means for cooking food on board?

Mr. EHRICKE. This would be done essentially electrically. Much of the cooking would be done in closed containers to confine the distribution of odors as much as possible. I do not think people will be able to just cook everything there in an open frying pan because this gives too many odors. There are ways and means to keep this down so as to keep down the amount of odor absorber that is required here.

Mr. McDONOUGH. You have no outside ventilation coming into the cabin?

Mr. EHRICKE. No, sir; it has to be a closed system.

Mr. FORD. When is this feasible from a practical point of view?

Mr. EHRICKE. I would say about 5 years from the time we are permitted to go ahead. If tomorrow we were to get the order to go ahead with this project, 5 years from now it would be in a complete form.

Mr. McDONOUGH. What would it cost?

Mr. EHRICKE. Roughly $500 million to develop those upper stages and get the whole system functioning and setting up a station. Later on, in order to supply it, you need only one or two supply flights per year to replenish the stations nonrecoverable systems such as a little bit of water that gets lost, a little bit of air may get lost. Oxygen gets lost completely all the time. This has all to be replaced.

Then the people need fresh food and other material for their regular living and this has to be supplied. We calculated that 4 people in this station here would, over the period of a year, need 7,200 pounds of nonrecoverable supplies.

One cargo ship here, of the type I pointed out to you here, carries about 8,000 pounds of supplies. So it is fair to say, with this kind of cargo ship, one to two supply flights would suffice, but this does not determine the cost of maintaining the station because we do not yet know how often we have to rotate the personnel. If you have to rotate the crew, let us say every 2 weeks, then you would have to have 26 additional supply flights to get the people up and down. So, depending on how often you rotate the people, this would determine the cost of maintaining the station.

Mr. FORD. What is the purpose?

Mr. EHRICKE. There is a great variety of purposes. The main purposes are the following:

We do need a test bed in space. More and more people will press for it, I am sure.

We have now these chambers at Randolph Field where Farrell was sitting in. We have experiments at Wright Field where four people sat in the B–36 and so on, but this is only a partial simulation.

We need a station in which we can test equipment and gear that we later will need for deep space explorations.

We secondly need a test bed to test the crew, to really exist under actual space conditions.

The first crew that travels to the moon, or goes down to the surface of the moon, will not start being on the surface of the earth and just living a normal life and all of a sudden going out into space and being forced there for a week, and in case you go to Mars or Venus, much longer.

They will have to go through space-flight simulations like this one, and this is what gives you the space flight simulation.

Then you have the geophysical, weather observation and these things.

You can also launch artificial comets in the outer solar system and, of course, heavy satellites to Venus and Mars much more than from the surface of the Earth.

Mr. FULTON. Why is the best shape in the form of a tube instead of flying saucers or sphere?

Mr. EHRICKE. Let me say this: if you don't want gravity, if you don't want any centrifugal force, the shape plays no role whatsoever. Any shape is good enough. As long as you want centrifugal force, you want to have the lifting force as far away from the center of the rotation—you can do this with a minimum of material if you have just one tunnel between your hub and your crew.

If you have a ring, then you must make the diameter of the ring very large and your circumference goes up very, very much.

For small stations this is impossible to do. So if you take the doughnut shape you are forced right away into a big-station design.

Mr. FULTON. If you slip and fall out of the open hole at a point other than the point where the rotating is made, what would happen to you? Would you go right along with it as if you were a satellite yourself?

Mr. EHRICKE. You would have a slight additional velocity component due to the centrifugal force. If you all of a sudden were thrown out here, if all of a sudden the floor fell out and you would be hurled right out while you were in the bathroom, you would be hurt because you would not have your space suit on.

Let us assume you had a space suit on, you would go with the station.

Mr. FULTON. That is why you put it away from the fulcrum or turning point?

Mr. EHRICKE. That is why the entrance must be close to the tunnel point so you are not being thrown around in space by the centrifugal effect because here the centrifugal effect is practically zero.

Mr. McDONOUGH. Where is your navigating gear? Supposing one wants to come back to earth, who decides that and how is it done?

Mr. EHRICKE. I believe the decision as to whether the crew comes down will be made by whoever directs the project.

Now, as you can see here on this particular picture which shows the station fully assembled, you have two emergency gliders attached on each end. This is not shown here. They would sit here and there. If an emergency comes up, then the crew takes to these sorts of lifeboat rockets and goes down into the atmosphere.

They probably don't care where they land as long as they get away alive.

In a regular procedure the crew will be informed at some particular time, "4 hours and so many minutes from now supply ship number so-and-so will come up with a crew of 4 to relieve you boys in the station."

They will get ready, make all the preparations for leaving this and having the other guys taking over.

Then they take the 2 gliders with which the relief crew has come up and bring those 2 gliders back to the earth again together with themselves.

So the emergency gliders attached to the station will normally never be touched like a lifeboat rocket will never be touched except in an emergency. So the control of this will be from the earth.

They get exact instructions as to timing, flight direction, plus duration, and so on, that they have to fly. This will all be calculated on the surface and they get that command like a pilot today gets his commands from the ground, you do this and fly so high, now you go down to that level, if they have these waiting times.

Mr. FULTON. Where are the heating element and the communicating equipment?

Mr. EHRICKE. The heating element is way over here. There is a small nuclear reactor about 100 kilowatts total power output. It has about 800 pounds of water and lead in here for shielding purposes.

This gives you a shielding that shields the whole station so there is nothing actually affected by deadly radiation.

The rest here partly house your turbine, generator, recuperator, your rectifier and the rest is to get the weight further back and get the shielding down because the farther away you have the less weight you have to have for shielding.

Mr. FULTON. Can you use solar energy?

Mr. EHRICKE. Yes, however, primarily, we rely here on the reactor because the orbit of this station is not laid in such a form that you are always in sunshine. There is, incidentally, emergency electrical power equipment in the rear in the form of batteries.

I foresee for this station either an equatorial or polar orbit. In either case you are for a considerable length in the shadow of the earth and you could not use solar power.

In that case nuclear power is used.

Mr. FULTON. That instrument is no further ahead on development than you originally were when you worked on the V-2 rocket development?

Mr. EHRICKE. That is right. This is a relatively primitive thing we could start on right away, of course, incorporating the improvements that come up in 5 years, but it gives us the space capability and then the option to go ahead from that.

Mr. FULTON. If we had a lead and had the daring that you had when you advanced the V-2 rocket program, we in the United States would be launching on a program of this spaceship type at the present time.

Mr. EHRICKE. Yes, sir; this is correct.

Mr. NATCHER. Are there any other questions on either side?

Mr. MCDONOUGH. What about the spaceship that Lockheed is building at the present time?

Mr. EHRICKE. The Pied Piper project?

Mr. MCDONOUGH. Yes.

Mr. EHRICKE. This is an upper stage of slightly lesser performance than I have anticipated here. We could use it for supply flights. I think it is a very valuable project right now.

Mr. MCDONOUGH. They are putting the hardware together on that, are they not?

Mr. EHRICKE. That is right. We can put hardware together as soon as we are given the permission to go ahead, either by NASA or ARPA.

Mr. MCDONOUGH. In addition to Pied Piper, what other spaceship is there at the present time under production?

Mr. EHRICKE. To my knowledge, none, sir.

Mr. NATCHER. Mr. Ehricke, on behalf of our chairman, Mr. McCormick, and the other members of the committee, I want to thank you for your very fine statement and your appearance before the committee at this time.

Mr. EHRICKE. Thank you, sir.

Mr. NATCHER. You have made a fine presentation, Mr. Ehricke.

In fact, I would like to say to you advisedly that no other witness has appeared that has done any better. We certainly appreciate it.

Mr. EHRICKE. Thank you.

Mr. FULTON. I compliment you, too, sir.

Mr. EHRICKE. Thank you.

Mr. NATCHER. If there are no further questions, the committee stands in adjournment until 10 o'clock in the morning.

(Thereupon, at 5:20 p. m., the committee was recessed, to reconvene at 10 a. m., Thursday, April 24, 1958.)

ASTRONAUTICS AND SPACE EXPLORATION

THURSDAY, APRIL 24, 1958

House of Representatives,
Select Committee on Astronautics and Space Exploration,
Washington, D. C.

The committee met, at 10 a. m., pursuant to recess, in room 356, Old House Office Building, Hon. John W. McCormack, chairman, presiding.

Present: Representatives McCormack (chairman), Brooks, Hays, O'Brien, Metcalf, Natcher, Sisk, McDonough, Fulton, Keating, and Ford.

Also present: George J. Feldman, director and chief counsel.

The Chairman. The committee will be in order.

The first witness will be Maj. Gen. Bernard A. Schriever, commander, Air Force Ballistic Missiles Division.

We are glad to welcome you, General Schriever. Do you have a prepared statement?

STATEMENT OF MAJ. GEN. BERNARD A. SCHRIEVER,[18] COMMANDER, AIR FORCE BALLISTIC MISSILE DIVISION, UNITED STATES AIR FORCE

General Schriever. Mr. Chairman, I do not have a prepared statement. I am here to assist you and your committee in any way that I possibly can.

I do not have a prepared statement, but I have seen the statement that General Putt submitted and those of several other witnesses, related to the Air Force program, and I did not think I could add too much to what has already been said, but I shall be responsive to the questions you have.

The Chairman. How important do you think is the establishment of an agency in connection with the exploration of what might be termed outer space?

General Schriever. My feeling here is that the exploration of outer space should not be solely a military province. I think that there should be a civilian agency but I think any civilian agency that is established should not have an inhibiting influence on the military's being able to carry out its requirements in this very important area of the future.

---

[18] Schriever, Bernard A(dolf) (schree ver), air force officer; b. Bremen, Germany, Sept. 14, 1910; s. Adolf and Elizabeth (Milch) S.; brought to U. S., 1917, naturalized, 1923; B. S., Texas A. and M. Coll., 1931; M. A., Stanford, 1942; Nat. War Coll., 1949–50; m. Dora Brett, Jan. 3, 1938; children—Brett A., Dora E., Barbara A. Became flying cadet A. C., U. S. Army, 1932; commd. 2d lt. A. C. Res., 1933, advanced through grades to big. gen., 1953; chief staff Far East A. S. Command, 1943–45; assigned hdqrs. USAF, 1945–49, 50–54, asst. for development planning, ast. to comdr. Research and Development Command, 1954—. Decorated D. S. M., Legion of Merit, Air Medal, Purple Heart. Home: 603-25th St., Santa Monica, Cal. Office: 401 E. Manchester Blvd., Inglewood, Cal.

The CHAIRMAN. Projecting your mind, based on your knowledge and talks with others of competent ability, how important do you consider that research and technology are in connection with the national interest of our country in the field of what might be called outer space?

General SCHRIEVER. I think, first of all, we can identify certain military applications to ballistic missiles. The ballistic missile, for example, is a member of the space vehicle family.

Satellites for reconnaissance, communication purposes, have direct military applications.

There are other things that are less clear as to direct military applications for, say, putting man into space. We certainly have a lot of scientific data that we can get from exploration of space. There is certainly prestige involved in moving forward in that area which I think is an important element in the world today.

It is impossible, I would say now, for any man to predict exactly how important space will be for military purposes, looking into the future, 20, 30, or 40 years.

I feel strongly that we must put man in space. No matter how automatic you make machines the human mind is still superior to any machine that you can make. I am certain that we will find a very useful purpose for man in space and, therefore, I think a program leading to this is very essential.

The CHAIRMAN. Do you consider that it is important for the Congress to pass a law establishing a civilian agency that will recognize the immediate problems that confront us and the world from a military angle?

General SCHRIEVER. I feel strongly that the military should be permitted to carry out its own research and development for vehicles which have application for military purposes because it is important that the developer and the user work together.

However, there are many things that would only have a vague military application and these, I think, would properly fall under a civilian agency.

Furthermore, I think the scientific element in the country needs to have a greater outlet for exploration of space than might be provided to them if they solely used the military for that purpose.

The two agencies, the military and any civilian agency that is established, must, of necessity, work very closely together.

The CHAIRMAN. I do not think there is anyone on the committee that fails to recognize that fact, General. We are all practical men.

But it is your opinion that it would be desirable for the Congress to establish an agency of the nature proposed in the pending bill, along the lines of the pending bill?

General SCHRIEVER. I have not had time really to read exactly what has been proposed. If you are talking about the NASA, I have read enough to understand generally how this agency is to operate.

Certainly for one, I strongly favor using the NACA as a building block for this agency because we in the military have had long working relationships with that agency and they have been extremely satisfactory. We understand each other; procedures have been established; you have a body in being which you can build from.

So I would strongly favor that approach.

The CHAIRMAN. I will not ask any more questions. I just thought I would lay a foundation here because you are starting from scratch and submitting yourself to questions.

Mr. Brooks.

Mr. BROOKS. General, I am glad to see you back here. I have heard you testify previously and I think you are doing great work there in charge of the Ballistic Missiles Division of the Air Force.

We had a demonstration yesterday from the Ballistic Missile Division of the Air Force. Can you give us an insight of what happened yesterday?

General SCHRIEVER. At this moment, I cannot add anything. We have gotten some conflicting data. It takes a while to evaluate all this—our telemetering data and our optical and photographic data.

I think it will be a couple of days before we get a complete evaluation of the test. We have not recovered the nose cone—I can at least tell you that. I am not sure that we will recover the nose cone but at this moment I don't have any other information.

Mr. BROOKS. If you do not recover the nose cone, you will not be able, then, to find out what damage, if any, it sustained in returning to the atmosphere?

General SCHRIEVER. That is right. If we do not recover the nose cone the test has to be considered as only partially successful.

However, we do get telemetering data from the nose cone during its reentry flight, which, of course, gives us valuable data as to what happened. Recovery would be important in this instance, however.

Mr. BROOKS. Did you get the data on its reentry into the atmosphere?

General SCHRIEVER. We had ships down range. I have not gotten a report from them yet.

We did get telemetering data as far down as Antigua, which is about 1,500 miles down range, but that is not at the reentry point.

Mr. BROOKS. The press carried something to indicate that it was better than 5,000 miles. Is that correct?

General SCHRIEVER. We did not make such a release; no, sir.

Mr. BROOKS. I think the press carried it. Maybe they got a release from the code signals that were sent out.

General SCHRIEVER. They might have.

Mr. BROOKS. It has been suggested that this would be a proper question: How far was that to go? That was not a shot at the moon, was it?

General SCHRIEVER. No, sir.

Mr. BROOKS. How far was it desired for it to go?

General SCHRIEVER. There are certain things I cannot say for security reasons, but I can tell you it was a reentry test aimed at getting reentry data at ICBM ranges. ICBM ranges are anywhere from 3,500 to 5,500 miles.

Mr. BROOKS. So you intended to do better than 3,500?

General SCHRIEVER. Yes, sir.

Mr. BROOKS. The Ascension Islands are about how far from Banana River?

General SCHRIEVER. Forty-four hundred miles.

Mr. BROOKS. The press carried something about it. Supposing that the cone is lost and dropped in the sea below Ascension Island, that would be better than 5,000 miles.

25973—58——42

General SCHRIEVER. I can say that we had ships out on the range and that these were instrumented ships. The cone was intended to be recovered from the ocean.

Mr. BROOKS. You do not think it went over South Africa, do you?

General SCHRIEVER. I would like to think that it had, but I do not think it did.

Mr. BROOKS. Now, if you recover it, it will give you certain data. The cone that was recovered sometime back, which reentered, came back with substantially no damage to it. Is that right?

General SCHRIEVER. Let me say it was a successful reentry test from all the information I have on it, yes. That was the Army test.

Mr. BROOKS. You would not say it was not damaged? I saw it and it did not show any damage.

General SCHRIEVER. I do not know what you mean by damage. It was a successful reentry. It was not damaged in the sense of not being able to perform its mission.

Mr. BROOKS. You, as a technician, will use that term. I will say it was not damaged.

General SCHRIEVER. I will say it was not damaged, also, then, just to keep the record straight.

Mr. BROOKS. Now, is it the purpose of these ballistic missile tests to try to send one to the South Pole?

General SCHRIEVER. We have no such plan at this time.

Mr. BROOKS. Did the mechanism aboard this missile, which relayed back the information, perform satisfactorily?

General SCHRIEVER. Not completely.

Mr. BROOKS. In what respect did it fail? Most of this is already in the press, you know. That is the reason I am asking.

If it was something that was not in the press, I would not ask you about it, but we might as well have the official details as well as read them in the press.

General SCHRIEVER. I did not make this release to the press.

Mr. BROOKS. It was a pretty good release, was it not, General?

General SCHRIEVER. The release that was made simply said that we had made this test, that this was the first of a series of reentry tests, and that we were going to attempt recovery. That was the last release made.

Mr. BROOKS. Will you tell us how high that missile went before it started back on its return trajectory?

General SCHRIEVER. No, sir; I do not know actually how high it went. We do not have that data yet.

Mr. BROOKS. I understand it used a portion of the Explorer. How did that function? Was that a satisfactory arrangement?

General SCHRIEVER. We used the so-called Vanguard second stage. Actually, the engine was developed by the Navy for their Vanguard program. It is an Aerojet engine and we used that engine as the second stage. It is, you might say, a modified Vanguard second stage.

Mr. BROOKS. The press says that you proposed to use the Vanguard for a third stage, too, in the tests coming off in the near future.

General SCHRIEVER. Of course, there is a good deal of speculation about how we are going to do certain things—things about which no information has been officially released to the press.

Mr. BROOKS. The articles I read in the press were not very speculative. They were rather definite.

The counsel tells me that Dr. Hagen mentioned it in his testimony the other day.

Is it proposed that your tests will go right on through, but will be interrupted by other tests of Vanguard, for instance?

General SCHRIEVER. Our tests will go right on through.

You see, Vanguard has a launch pad adjacent to one of our launch pads for the Thor program. They have one launch pad, we have three.

There is little or no interference between the tests.

Mr. BROOKS. You are not prepared, though, to launch two at the same time, one from the Navy and one from the Air Force, are you?

General SCHRIEVER. We have launched more than one missile a day. We have launched as many as three missiles from Cape Canaveral in a single day.

There is some interference probably when you launch more than one, but this can be worked out.

Mr. BROOKS. Have you launched three major size missiles, or satellite type missiles?

General SCHRIEVER. No, not major missiles.

Mr. BROOKS. They were smaller missiles?

General SCHRIEVER. We launched 2 large missiles and 1 small missile in one day at the cape several months ago.

Mr. BROOKS. What would you say about the accuracy of the medium-range missile now? Have we developed it to the point that it is dependable and accurate?

General SCHRIEVER. We have had very successful guidance flights with the Thor.

The problem of reliability is still one of our major problems, and it will continue to be. That is one reason why we have to test as many missiles as we do—to build up the reliability.

Unfortunately, missiles are not like airplanes. You can take an airplane up and bring it back down again for inspection and analysis. Fire a missile, though, and you've had it as far as that particular missile is concerned.

Our program contemplates the firing of a considerable number of missiles in the development program and one of our major objectives is to improve the reliability as we go along. We know from experience this is necessary.

Mr. BROOKS. And the responsiveness, too? Did you control that missile until it hit the water or land or its destination?

General SCHRIEVER. Yesterday's was not a guided flight.

Mr. BROOKS. It was not guided in any sense of the word?

General SCHRIEVER. The missile had a control system and automatic pilot, but it was not guided in the sense of having a guidance system with which you attempt to hit a pinpoint target.

Mr. BROOKS. You had no land control, then? Is that what you mean?

General SCHRIEVER. Yes, all these flights are programed flights and we can predict quite accurately the area in which it will impact. By a "programed" flight I mean one in which the missile trajectory is computed and introduced into the guidance system before launching.

Mr. BROOKS. You have control from some land areas. Was your control of that missile effective?

General SCHRIEVER. The controls are part of the missile itself. One portion of the control system is the automatic pilot. The missile, of course, is radar tracked from the ground during its powered flight so that in case it goes off course and endangers any land areas, it can be destroyed by a signal from the ground.

Mr. BROOKS. You can destroy it then and have that much control over it. You have some control in the direction and elevation, do you not?

General SCHRIEVER. Not from the ground on this type of flight. There are different types of guidance systems, too. The intermediate missiles for example, use what we call an all-inertial guidance system. This system has all its guidance equipment actually on board the missile and follows a trajectory which is programed prior to launching. It is not controlled from the ground at all.

Mr. BROOKS. Is this the fish-out-of-water type operation that has been referred to before this committee previously?

General SCHRIEVER. That term does not ring a bell with me, sir; I am sorry.

Mr. BROOKS. That is sending up a missile until it jumps out of the atmosphere into space and then returns into space.

General SCHRIEVER. Yes, sir; all of our longer range ballistic missiles move through the atmosphere, operate in space, and then return.

Mr. BROOKS. Was there any effort to get the elevation there on that flight, or was that the range that you had an interest in?

General SCHRIEVER. You have to get elevation in order to get range.

Mr. BROOKS. Your prime purpose was the range?

General SCHRIEVER. The prime purpose was the range; yes, sir.

Mr. BROOKS. The elevation was only incidental, as it would lengthen the range?

General SCHRIEVER. That is right.

Mr. BROOKS. There was nothing alive aboard their satellite; no animals?

General SCHRIEVER. Yes; however, this was primarily the first of a series of our long-range reentry tests. Although the vehicle was primarily designed to obtain reentry data for a nose cone of advanced design, we were also able to place a mouse on board and thereby accomplish additional space research.

The mouse was carried in a specially fabricated compartment within the nose cone equipped with air purification and breathing apparatus. The experiment was conducted under the supervision of the Aeromedical Field Laboratory and was designed to help identify and solve such problems as weightlessness and other factors which will affect man in space.

Mr. BROOKS. That is all, Mr. Chairman.

The CHAIRMAN. Mr. Metcalf.

Mr. METCALF. I will reserve my time, Mr. Chairman.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. General, in your opinion, will we be able to shoot a rocket close to the moon by the year 1960?

General SCHRIEVER. Yes; we certainly can. In fact, the Air Force is planning an attempt late this summer.

Mr. NATCHER. General, do you further believe that by the year 1966 we will be able to land on the moon?

General SCHRIEVER. You mean with a man? A vehicle fully instrumented and sending a manned rocket? In talking about this, I would like to specify that I am talking from my own personal opinion and judgment.

Mr. NATCHER. That is right.

General SCHRIEVER. My technical opinion is that there is no reason why we cannot land on the moon by that time period, 1966.

Mr. NATCHER. Further, in your opinion, General, do you believe that by the year 1970 we will be able to establish a permanent base on the moon and have a supply system set up to maintain the base?

General SCHRIEVER. This might be possible, but it would be very expensive to accomplish this by that time.

Mr. NATCHER. Give us some idea, General, approximately. I know you are not able to fix the amount, but approximately how much would you say such a program would cost?

General SCHRIEVER. I would really have to pull this out of thin air, because I have not actually given much thought about setting up a station on the moon, although I have read about such schemes.

The cost certainly would be in the severals of billions of dollars. This estimate, however, is not associated with the first question that you asked with respect to the moon.

Mr. NATCHER. General, as I understood your answer a few minutes ago, you have read the bill that is before the committee that sets up this Agency as far as outer space is concerned.

General SCHRIEVER. No, sir; I have not read the bill.

Mr. NATCHER. Assuming that this bill provides for an agency controlled by civilians, a civilian-controlled agency, in your opinion, General, would that be the best procedure?

General SCHRIEVER. I think it would.

I also want to qualify my answer by saying I feel also that the military must carry out their proper portion of any space program.

Mr. NATCHER. I understand.

Thank you, Mr. Chairman.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. General, as I understand your answer, then, to the gentleman from Kentucky, you have not read the bill?

General SCHRIEVER. No, sir.

Mr. SISK. Are you generally familiar with what it proposes to do in the type of agency it proposes to set up? I believe the bill calls for a 17-man board, directors, and so on.

Are you familiar with that proposal?

General SCHRIEVER. I would say generally I am. Its functions would be different from those of the present NACA, which is really a committee.

The CHAIRMAN. That is true, General. At the present time the Board is really the operating level in the present setup and the Director is under the Board. Whether in practical operation he is, that may be a different proposition. But this, in substance, would set the Board under the Director and principally in an advisory capacity.

Mr. SISK. Thank you, Mr. Chairman.

Let me ask you this question, General. What is your opinion of ARPA, the Advanced Research Projects Agency?

General SCHRIEVER. Well, I got myself in trouble on this one once before.

Let me say that when I testified previously on this subject, I did so before the group was actually set up. I stated that I felt such an agency at the Department of Defense level was highly desirable, provided that it would be positive, constructive, and one which could establish policy and make decisions in this whole area.

I felt that such an agency should use the operating management which was available to it within the three military services. If it did that, then I thought this was a constructive step.

Up to this point ARPA appears to be doing that.

In other words, they are using the service management organizations that exist and in which we have technical teams, procurement teams, and management organizations in being.

For example, they have directed my organization to undertake a part of their overall lunar probe program. This seems to me a step in the right direction.

Mr. SISK. None of these questions, General, are intended to put you on the spot. But we have been delegated certain responsibilities here, we have before us certain legislation, and we are going to be called upon to make some recommendations.

I am merely interested in your opinion on some of these things. It had been my understanding that at the inception you opposed the Advanced Research Projects Agency. I have no desire to put you on the spot, but I wondered what you think of it since it was established.

General SCHRIEVER. In the early thinking they seemed to be considering a big operating agency. I saw some of the draft proposals. This concept I did oppose.

However, I have no fault to find with their initial operating arrangements, and so long as they continue to function as they are doing now, I think they will be a highly constructive element within the Department of Defense.

Mr. SISK. Do you feel they have tended to stabilize the program?

General SCHRIEVER. They have been helpful in laying the base for an astronautics program.

Mr. SISK. Correct me if I am in error, but I think in the past you indicated you felt that it took altogether too much time to get decisions from Washington. Do you feel there has been any improvement, or any change in that situation since you made earlier statements, if the statements are correct?

General SCHRIEVER. I did make such statements. The trend is now in the right direction, however. I guess that when you are at the operating level, as I am, you are never quite happy with the time it takes to get decisions made by higher authority.

But I can honestly say that the trend in the decision-making process, as it relates to the program for which I am responsible, is in the right direction.

Mr. SISK. Now, in answer to a question from one of the other gentlement a few moments ago, you referred to the NACA as a possible vehicle or nucleus around which a new agency might be created.

To what extent do you feel that NACA has been successful in its objectives and in the handling of the program over a period of a great many years, I believe since 1915?

General SCHRIEVER. NACA has been in being, I think, quite a bit longer than that. We had NACA down at Langley Field when I first came to the Air Force in 1932.

Mr. SISK. Maybe you misunderstood. NACA was created in 1915.

General SCHRIEVER. I am sorry, I thought you said 1950, sir.

Mr. SISK. It has been in operation over 40 years.

General SCHRIEVER. Yes, it has been in operation a long time.

I have been in research and development in the Air Force on and off—mostly on—since 1939 when I first went to Wright Field. I can only speak with praise concerning the NACA and what they have accomplished.

For example, in our ballistic missile program they have given us very, very great support.

For example a very large part of the wind tunnel high-speed testing done by the Moffett laboratories in California has been in support of our nose-cone work.

The Cleveland Propulsion Laboratories have also done a lot of work in the rocket field for us.

So I think both from an accomplishment standpoint and from the standpoint of relationships with the NACA there has been a highly successful partnership. I know the Air Force, and I am sure this is true of the Navy as well. The Army has had less dealings with the NACA in the past.

Mr. SISK. General, if they are doing and have done a good job, what is the need of a new agency?

General SCHRIEVER. I would rather measure the need in terms of widening the scope of their responsibility. I consider it more or less in terms of the NACA taking this job on with, perhaps, a little greater authority and with a broader scope of responsibility. I think the transition from the earth's atmosphere to space is a natural one and, as a matter of fact, we have been operating on the edges of space with the Air Force's high-altitude airplanes for the past 5 or 10 years.

Mr. SISK. The mere fact that we upgrade the NACA and give it a new name, say, add space and add astronautics to aeronautics, is not going to change operations generally or widen the scope, is it?

General SCHRIEVER. They have not, specifically, had responsibilities out in space, as such. They have been associated with aircraft, and these aircraft have been traveling at very high altitudes.

Mr. SISK. Who does have authority in space, if they have not had it?

General SCHRIEVER. I do not think any agency outside the military has really been in that area.

Mr. SISK. Is there any restriction on them, or any other agency, as to the authority and responsibility for exploration in space? Have we limited it in any way?

General SCHRIEVER. I am not sure. I would have to read the charter of the NACA and make my interpretation. I think that Dr. Dryden, whom I have talked to, and also Jimmy Doolittle, feel there is a need for an expansion of the charter to incorporate astronautics, although I have not, specifically, talked to them about that nor questioned them about it.

Mr. SISK. So that we completely understand each other, there is nothing critical toward you or NACA in my questions. However, I am concerned over a great deal that has gone before and, particularly,

some testimony before this committee. Certainly it seems to me, if all we propose to do here is simply to upgrade and change the name, possibly even give a little additional responsibility to NACA, I question whether that is the answer. That is the reason, primarily, for these questions. Now, it certainly was not necessary to obtain any new legislation for you to go into space?

General SCHRIEVER. No.

Mr. SISK. So, there is no need for legislation to give NACA any additional authority to explore space or to consider space in their program, is there?

General SCHRIEVER. I am not entirely certain about that, sir.

Mr. SISK. This is the point that I had in mind, General. As I say, I am not critical of Dr. Dryden or of the NACA. I think that, over the forty-odd years they have been in existence, the record shows that, apparently, they have moved forward generally, but have we reached a stage, and are we in any position today, where their type of progress no longer meets the need?

General SCHRIEVER. At least the inference is that we should progress faster, but I am not sure that the NACA could not do the job under the present charter.

I think that, if you were set up a completely new agency starting from scratch, you would undoubtedly slow things up before you would gather the needed momentum.

You would then have another agency that would have to set up its administrative procedures and its working relationships with other agencies of the Government and with industry and so forth. I, personally, feel that the NACA is a proper approach to this job on the civilian side.

Mr. SISK. You do not feel that the NACA and its type of operation has, at any time, attempted to restrict freedom of operation by our scientific or engineering brains or minds in this country. You feel the hundreds of millions of dollars which, of course, they have had available, has been well spent, in your opinion. Is that right?

General SCHRIEVER. I think so; yes, sir.

Mr. SISK. Just how urgent do you feel this program is? By that, I mean this probing into space and conquering space, if you will permit me to put it that way, although I realize that we will conquer by degrees. To what extent do you attach urgency to this, General?

General SCHRIEVER. I would say that we should carry out a sensible program in the exploration of space. I would not attach the same degree of urgency to space exploration, per se, as I would attach to the development of those space weapons which will be vital to the national security during the next 10 years. I am talking now of advanced ballistic missiles and satellites and so on.

Mr. SISK. You think the emphasis should be on the military aspect, rather than on getting into outer space for other purposes?

General SCHRIEVER. I don't want to be exclusive here. In these matters there is always a question of priority, and there is always a question of how much of your reserves you can afford to put into these various ventures.

Now, there is no question but that we can do a great deal of exploration in space with relatively small additions to the present foundation that has been established in the military programs. I am not saying,

however, that we should try to do, all at once, all that may be technically possible.

We should make our resources available to a civilian agency. If they don't use them, the program will be extremely costly. It has already cost an awful lot to come as far as we have today.

Mr. SISK. To conclude this line of questioning, General, it seems to me we have two schools of thought: One seems to indicate business as usual, doing business at the same old stand, and by that I mean NACA, with a little upgrading. On the other hand, we have a school of thought that feels there is a certain urgency in this program; that we need to progress and place great responsibility in the Director, to carry forward much more rapidly than we have been. To what school do you belong, would you say?

General SCHRIEVER. First of all, I cannot, in my mind, divorce the military program from the so-called civilian space program. We have been and still are carrying out the military space program, first in ballistic missiles, and now in military satellites, under the very highest priority and with the greatest degree of urgency that I have known since I have been in the service.

I expect that space exploration will proceed at a pace that is pretty closely associated with that of the military program, because military resources will have to be used. However, it is my personal judgment that space exploration, in the pure research sense, does not carry so urgent a priority as does military space development, sir.

Mr. SISK. I have one concluding question, General Schriever. I believe I am correct in stating that you indicated that, by using our present hardware or available equipment, the IRBM and ICBM with boosters, we could put much greater weights into space and, possibly, get to the moon by 1959.

Would you want to make any comments on that? I am not quoting you; I am merely summarizing or paraphrasing what your position has been.

General SCHRIEVER. This is correct.

Mr. SISK. Do I understand that you are saying that you have hardware in being, as a part of the IRBM and ICBM, equipment, engines, products, boosters, with which we could put into orbit today much greater weights than we have heretofore?

General SCHRIEVER. Let me say this: You speak of "today." We are today only in the development phase. The idea I meant to convey was that the hardware which is under development in the ICBM and IRBM programs will put much greater weights into orbit than we have so far put up.

Furthermore, I have stated elsewhere that the hardware and facilities in these programs could provide as much as 90 percent of the hardware and facilities required in space exploration during the next 5 to 10 years.

Mr. SISK. That is all, Mr. Chairman.

The CHAIRMAN. Of course, General, the use of laboratories and facilities should be coordinated so that there will be no unnecessary building up of two parallel systems. Is that right?

General SCHRIEVER. That is right.

The CHAIRMAN. As I analyze your state of mind, you are recognizing what anybody should recognize, namely, the immediate situation that confronts the world and our country?

General SCHRIEVER. Right.

The CHAIRMAN. While we have a civilian Government, its survival is dependent upon military victory in case of war.

General SCHRIEVER. That is true, and I am sure you will agree that what we want to do is to remain strong enough so that we will not have a war. We can only do this by having the most modern weapons available, at least in view of the present world situation.

The CHAIRMAN. Nobody could disagree with that statement.

On the other hand, I am not an adherent in my personal views to a fixed policy of nonaggression. I am not particularly of that school. I never believe in advertising my punches completely to an enemy or potential enemy.

Mr. Fulton.

Mr. FULTON. Thank you, Mr. Chairman. I am going to limit my questions to 5 minutes on the nose, so that we will move a little faster.

When the rocket was shot into the air yesterday by the Air Force, it was a planned course and a planned target area, was it not?

General SCHRIEVER. Yes, sir.

Mr. FULTON. It has been said that the planned target area was in the vicinity of the Island of Ascension. That is correct, is it not?

General SCHRIEVER. Yes.

Mr. FULTON. It went over the regular missile course laid out from Cape Canaveral to the Island of Ascension. Can you tell us if there was any deviation in flight that would make the particular missile appear unmanageable or was it a successfully inertial guided mission flight?

General SCHRIEVER. It was a preprogramed flight using an automatic pilot. The missile was definitely not unmanageable; otherwise it would have been destroyed by range safety.

Mr. FULTON. So why do we not in the United States, and you in the Air Force, say that we are now up to where Russia has been on her ICBM, that we have had the equivalent of an ICBM flight that has been successfully guided on a program flight to a target area and it has reentered the atmosphere as scheduled? That is what Russia did in the latter part of August, last year. Why do you not make the same kind of announcement, that you are now equal with Russia on the ICBM planned and programed flight? It that not right?

General SCHRIEVER. No.

Mr. FULTON. Why is she then still ahead of us after what happened yesterday?

General SCHRIEVER. I do not think you can classify this missile as an ICBM. It was strictly a research vehicle to obtain reentry data. You must remember that in an operational missile the total nose cone-warhead combination dictates certain weight requirements. For certain test purposes you can use missiles of weights which are considerably less than might be required for an operational ICBM.

Mr. FULTON. As far as you know, from what Russia has released, this is the equivalent of her four-to-five-thousand-mile test going northeast over Astrakhan up into Siberia.

So why do you not say we now have the equivalent rather than hesitate and say we have not similarly had a 5,000-mile ICBM test, giving the size, that was according to a planned program and entered the correct target area on schedule?

That is what you did.

General SCHRIEVER. Well, we do not have all this data confirmed yet, as far as this particular flight is concerned. I want to make that point clear.

Mr. FULTON. Yes, but you know it entered the target area, do you not?

General SCHRIEVER. No, I do not.

Mr. FULTON. It went according to the program and plan. You telemetered it on a certain course and it was in the regular target area in the vicinity of Ascension Island. It may not have been seen to have plopped, but somebody knows it is in that area, does he not?

General SCHRIEVER. We do not have such data now that has been evaluated to completely confirm this.

Mr. FULTON. I am in the newspaper business. When you are in competition with somebody and you are in politics, you do not give the other guy the edge and minimize yourself. You just say you are equal to the other guy.

It is hard for me to get the Air Force to say they are equal to anybody in this race for propaganda.

As a matter of fact, from some information I have that is classified, I think you are equal on this particular flight and that you have had a space vehicle that has reentered on a program flight with proper decelerating devices and it has been telemetered, so that you are successful. Why do you not say it?

General SCHRIEVER. Well, I would like to say it.

Mr. FULTON. Then let us say it.

General SCHRIEVER. You are not going to get me to say it simply because, as far as this last flight is concerned, the data just is not in to the point where I can say it.

Mr. FULTON. Well, you promise to say it, if it is true and you can confirm it?

General SCHRIEVER. It still is not an ICBM.

Mr. FULTON. Is not a missile that is a space missile with a payload carrying ability which has a range of a programed flight over 5,000 miles an ICBM or am I wrong?

General SCHRIEVER. You do not have an ICBM until you have, first, discreet guidance, not just a programed flight by an automatic pilot, and, second, the weight-carrying capacity too for a significant warhead.

Mr. FULTON. Then do you believe that Russia's announcement of last August that she had successfully carried out an ICBM flight means the same thing that you are talking about?

General SCHRIEVER. I personally cannot give you an honest opinion on that. I have to take what the intelligence agencies say.

Mr. FULTON. If you will just say yes or no, or I do not know, that will help us.

General SCHRIEVER. I don't know.

Mr. FULTON. May I finish with this.

Krafft Ehricke, who is the preliminary designs chief of the Astronautics Division of Convair of San Diego, was here yesterday. He recommended immediately starting on a space ship that is not designed primarily for military purposes, but is maneuverable so that it might, in the long run, be so used. He estimated the cost of that as a half billion dollars.

Likewise, he said that on the capability we have now with on the Jupiter C and the Vanguard, as well as the Atlas and the Thor, we have thrust or booster power necessary to put that kind of space ship into outer space. Likewise, we can provision it by weekly or bimonthly trips.

First, do you think it is feasible? Second, would you recommend that such a program be undertaken by someone?

Third, would you recommend that the Air Force do it?

General SCHRIEVER. First, it is feasible, but certainly not in the immediate future.

Getting man up into space and providing the right kind of environment for him is still a major problem ahead of us.

Mr. FULTON. Then you would agree with Von Braun when he says it is important to put a man in a capsule and shoot him 150 miles in the air, or would you refer to it as did by Dr. Dryden, that it would be in the nature of shooting a woman out of a cannon? Whom do you agree with?

The CHAIRMAN. Or do you have your own views?

Mr. FULTON. Is it effective? Should it be done, or is it just like shooting a woman out of a cannon?

General SCHRIEVER. I think there are possibly more effective programs than doing it that way. There are a number of ways in which you can get man into space. A number of proposals have been made. I do not know that you gain too much by simply putting somebody up to 150 miles and then letting him come back down again.

Mr. FULTON. You would then advise against the program at this time as a practical matter?

General SCHRIEVER. I would advise against that one. I would much prefer a program in which we first orbit, say, animals, while, developing a recovery technique for the animals, and then go on to manned flight in that manner.

Mr. FULTON. Thank you.

That is all, Mr. Chairman. My time has expired.

The CHAIRMAN. We are very glad to welcome back to the committee Congressman Hays of Arkansas. I hope that on the floor of the House and when we have time to get into executive session, he may give us some of his impressions of his recent trip to the Soviet Union.

Mr. KEATING. I hope so, too, Mr. Chairman, and I hope he converted a good many there to the Baptist cause.

Mr. BROOKS. Mr. Chairman, I hope, too, he brought back some information for the committee on the question of Russian guided missiles.

Mr. FULTON. And I hope that when we send our Aga Khan, the head of the Southern Baptist Conference, that he is given his weight either in Arkansas cantaloupes or Russian watermelons instead of diamonds when you get over there.

The CHAIRMAN. Of course, you cannot let my church out, the Catholic Church. This is a little pleasant interlude, General.

General SCHRIEVER. Yes, sir; I am enjoying it, too.

Mr. KEATING. I yield to Mr. Ford, who has another committee meeting.

Mr. FORD. As I understand part of your earlier testimony, General, you indicated since 1939 you had been concentrating more on research for the Air Force.

General SCHRIEVER. Research and development: The only time I have not been directly associated with research and development activity for the Air Force was during the war, when I was overseas for three and a half years.

Mr. FORD. I believe that, at least in more recent years and perhaps in earlier times, you were in the research and development programs that were more or less of the advanced type?

General SCHRIEVER. My last assignment in the Pentagon was chief of the Development Planning Office which has the major objective of studying the next generation of weapons that the Air Force should be putting their money on.

Mr. FORD. In that capacity, I am sure, when you felt you had good ideas and good programs beyond the normal military scope, you have had some frustrations in trying to sell such programs, have you not?

General SCHRIEVER. It is always difficult to sell new programs.

Mr. FORD. It is difficult to sell new programs, particularly to those who have to meet conventional needs right at the moment.

General SCHRIEVER. There is always a compromise that has to be reached between a force in being and a force to be; a compromise between current production payments and the fund requirements to initiate a major new development program. There are always good and valid questions that arise, too, either from the technical, operational, or logistics standpoints, whenever you introduce a completely new operational environment or new logistics systems to support it.

Mr. FORD. I do not question the difficulty of making choices. However, I believe it is true that the establishment of your own agency in California made the job of getting the ballistic missile program advanced easier. Is that correct, General?

General SCHRIEVER. Yes; I think so. We did have the support of the Air Force right from the start and the ballistic missile program has been given the highest priority. I had this strong backing to begin with. The nature of our management organization has been such that we have been able to speed things up by taking concurrent action right across the board in all areas required to produce complete weapon systems and their operational and logistic environment.

In short, we are pushing the whole program forward on the broadest possible front—not just the research and development phase alone.

Mr. FORD. When you are operating with a new idea, intermixed with a lot of more or less conventional ideas, sometimes you do not get the needed emphasis on the new idea in relationship to the other.

General SCHRIEVER. I think this is true.

Mr. FORD. For example, it is true that since ARPA was established there has been a greater emphasis on the lunar probe program than we had prior to its establishment?

General SCHRIEVER. Yes. This is true speaking of the Department of Defense level, but there has been considerable interest in doing this, say, in my organization and also in the Army's organization.

Mr. FORD. I agree with that, but you did not get any action to proceed until ARPA took over the responsibility?

General SCHRIEVER. That is right.

Of course, it is very important that the right people be selected for ARPA. Now, Dr. York, who is an old friend of mine, is a very fine choice for the chief scientist in that organization. I do not know

Mr. Johnson, but he has certainly a good record and his office has been moving forward quite aggressively.

Mr. FORD. Using that as an illustration, is it fair to conclude that expanding NACA to an NASA might give the same impetus to the civilian side of space exploration?

General SCHRIEVER. I think that this certainly is a logical conclusion. I had quite a long talk on this subject several months ago with some of the scientists who are with Dr. Killian. I have known these men for some time, and they brought up this very point.

This was the reason why they felt it was a good and necessary move to establish an agency outside the military, with singleness of purpose with respect to exploration of space. From a philosophical standpoint, I agree.

Mr. FORD. It seems to me, if you look back over history, in recent years even, whenever we set up such an agency, and we have to assume it is well managed and has a good purpose, that it does seem to provide an impetus. It does seem to get action, which you have not been able to get heretofore, where the idea was crowded in with a number of other things which were, perhaps, equally important today, but not so important in the years ahead.

I gather from your testimony that since ARPA has been operating your relationships with it have been very satisfactory?

General SCHRIEVER. Yes. We, of course, run into certain administrative problems which you could expect, but we have ironed those out and in our opinion we have been working very well with them; yes.

Mr. FORD. Do I understand that they expect to have a staff of no more than 20 or 25? It is not to be a huge organization, but primarily one that will give direction in the military areas so far as space and related programs are concerned?

General SCHRIEVER. I think if they stick to that, in other words, a relatively small staff—I would not want to say whether 20 or 30 is the right number—but if they stay small and have high quality people they are certain to do a constructive job.

Mr. FORD. In the bill it provides that on this board of 17 there shall be at least 1 who shall be from the Department of Defense.

Do you think there should be a legal requirement that there should be more than one from the Department of Defense?

General SCHRIEVER. My feeling here would be that probably more would be better because this agency will have to draw on the military for much of its resources, if only to avoid costly duplication.

I think this is absolutely essential. One out of seventeen seems hardly enough. I don't know what the right number should be, but I feel it should be more than one.

Mr. FORD. Should it be one from the military side of the Department of Defense, or from the civilian side of the Department of Defense?

General SCHRIEVER. I believe they should come from the military side. Certainly if all three services are carrying on the programs which very likely will be carried out to meet the requirements of the total Defense Department, it would probably be well to have representatives from each of the services.

Mr. FORD. I have one final question. Is the Thor program on schedule at the present time?

General SCHRIEVER. It is on schedule and our program calls for having a squadron overseas in England by the end of this year.

Mr. FORD. The test that was conducted last week, was that an adverse one?

Let me put it this way: Was it one that indicates that you are still on schedule, or are you going to get behind schedule?

General SCHRIEVER. In the test Saturday we had an engine failure right after takeoff. The missile lifted off a few feet. However, the malfunction was one of those random failures that we run into occasionally—one of those incidents arising from the search for greater reliability. It was our first such failure in the whole program, and it was the first missile that we have lost at the launch pad during the last 9 or 10 firings.

As a matter of fact, we have had very good engine operations overall, although we have problems, as you might expect. We do have a problem in the engine right now, but it is not fundamental.

Mr. FORD. Thank you very much.

The CHAIRMAN. General, following Mr. Ford's line of questioning, the bill provides for at least one representative from the Defense Department. Of course, that could mean more than one. That is for the President to decide. The President is also Commander in Chief.

General SCHRIEVER. Right.

The CHAIRMAN. Assuming the committee should increase the number on the Board and provide a specific number, instead of specifying each service, have you an opinion as to whether the recommendation should be made from the Defense level by the Secretary of Defense?

General SCHRIEVER. I would say that the Secretary of Defense ought to be the one.

The CHAIMAN. There has been a lot of discussion, general, concerning this. You can see there is a lot of discussion about this among members. Other witnesses have been asked questions that you and others do not have the benefit of. There is considerable thought among the members of the committee, if I grasp their minds, and I am expressing my own, too, that in addition to whatever Defense Department representatives might be on this Board of 17, it would be very well from a workable angle to provide in the bill the establishment of a liaison group between this new agency and Defense on the working level where things can be brought up quickly, where things meet, where they can discuss and decide and get quick action. It would not be one of those groups that meet occasionally, but would be constantly available.

What would be your thought on that?

General SCHRIEVER. You mean a permanent staff?

The CHAIRMAN. Exactly?

General SCHRIEVER. I would say that our relationship with the Atomic Energy Commission through the Military Applications Office, which has been headed in every instance by a military man assigned to the AEC, has worked very well.

I would think that machinery of that kind would be required.

The CHAIRMAN. It is a question of getting men together.

General SCHRIEVER. That is right.

Mr. KEATING. And that machinery would be the best way of coordinating the military with the civilian activity?

General SCHRIEVER. In my organization out on the west coast, I have a large segment of the Strategic Air Command right there with me—a part of the Strategic Air Command Headquarters.

The same is true of the Air Materiel Command.

Ditto for the Training Command.

The fact that we are working together in the same location permits us to understand each other, to resolve quickly problems that need to be resolved. There is always a need for some compromise among operational, technical, and logistic factors.

You can do this best by living together and working together, and you can do it faster.

I am all for this sort of approach.

Mr. KEATING. Would you think it desirable that we establish this in the legislation, or leave it to executive action?

General SCHRIEVER. I think you ought to put it in the law, sir.

Mr. KEATING. You were asked also about the inclusion of more than one military representative among the 17 Board members. There has been some representation to us that it would be desirable to have one each from the Army, Navy, and Air Force. Nobody mentioned the Marines.

Now, do you not feel that if we increase the one and have the additional members named by the Secretary of Defense, it would be more nearly in line with the thinking of the reorganization plan which was presented to Congress recently?

General SCHRIEVER. I would think that you should leave it up to the Secretary of Defense to name or appoint the members of this Board.

Mr. KEATING. I want to refer to the question posed by the gentleman from California, Mr. Sisk.

As I envisage this proposed legislation, it is very much more than a simple upgrading of NACA. It is the creation of a completely new agency into which the present functions of NACA will be absorbed.

I do not think we should be confused by the similarity in names and the change from NACA to NASA.

For instance, under section 6, subsection (3), of this bill, among the functions of the new agency it is proposed:

> That they may develop, test, launch, and operate aeronautical and space vehicles.

There is nothing of that nature in the present functions of the NACA, is there?

General SCHRIEVER. They do operate aircraft, for example, at Langley Field and at Moffett Field in California.

Mr. KEATING. They actually operate them?

General SCHRIEVVC. Yes.

Mr. KEATING. Do they acquire, construct, improve, repair, operate, and maintain laboratories, research and testing sites and facilities? Do they do that?

General SCHRIEVER. Yes; they do.

Mr. KEATING. Of course, the next one is manned and unmanned aeronautical and space vehicles. They, of course, do not operate any space vehicles?

General SCHRIEVER. No, but they do operate aircraft and they have missiles and testing grounds and, of course, all the laboratories are under NACA direction.

Mr. KEATING. I thought the implication in it, which may not have been intended by the question put by the gentleman from California, was that this legislation represented, more or less, business as usual. Do you not think that the enactment of legislation of this, or similar character, would be a very important step forward in space development?

General SCHRIEVER. I think it would place greater emphasis on it, greater recognition from a national and organizational viewpoint. It would then be clear that the responsibility would be centralized in one agency, one is outside the military, and I think its real effectiveness would be determined by the kind of people that could be attracted to the organization.

Mr. KEATING. Unquestionably the naming of the Director would be extremely important here, as would the Board or Commission or however we may set it up.

General SCHRIEVER. That is right.

Mr. KEATING. Let me get back, however, for a moment to your answer to me about the present functions of NACA.

You said they operated aircraft, for instance. They do not directly contract for the construction of aircraft, do they?

General SCHRIEVER. No; they do not. They will occasionally enter jointly with the Air Force or the Navy in a program for experimental aircraft. They are in the X–15 program, for example.

The NACA is one partner in that project.

Mr. KEATING. In that project, for instance, they have contracted directly?

General SCHRIEVER. I would have to check this because I have not been involved in this recently, but I am quite certain that the contract is either a Navy contract or an Air Force contract, with the NACA as a full participant. They do not, I believe, contract directly with industry for the procurement of airplanes.

Mr. KEATING. They are given authority under this, as worded, to do that?

General SCHRIEVER. This bill is worded differently.

Now, at present when we turn the airplanes over to NACA for research and experimental purposes, they belong to the NACA to operate and do with as they please.

Mr. KEATING. The point I am getting at is that this is a very fundamental extension of their present authority.

General SCHRIEVER. That is right; it would be.

Mr. KEATING. You spoke of the failure of an engine the other day which as you have pointed out, was a failure after a number of successful launchings.

Is there any doubt in your mind that the Russians have had plenty of failures in their launchings?

General SCHRIEVER. Failures are part of the business. If they have not had failures they must be 50 feet high.

Mr. KEATING. You do not consider they are 50 feet high?

General SCHRIEVER. I don't consider they are 50 feet high.

I am sure they've had failures. It is just part of this business of development.

Mr. KEATING. As I understand it, your intelligence is that when they launched an ICBM it had a payload equivalent to a conventional warhead for that type of weapon. Is that what you are telling us?

General SCHRIEVER. I think I had better not get into that.

Mr. KEATING. The reason for the answer that you gave to the gentleman from Pennsylvania in saying that the recent launching at Cape Canaveral was not an ICBM launching was because your payload was not necessarily of such weight? Am I correct?

General SCHRIEVER. This is substantially correct. Yes, sir.

Mr. KEATING. When do you normally have the results of those tests? Is it a matter of 2 or 3 days, or is it more?

General SCHRIEVER. Determining the final results takes longer than that. Usually we get a detailed technical evaluation report after about 2 weeks, but after the third day, approximately, we do have a pretty thorough evaluation of the data. By then we at least know if we have had trouble; we have isolated the trouble and we know what it is.

We may not know at this particular stage precisely what caused the trouble—that takes further analysis. However, we will know the results of the test in terms of overall performance. If everything works right in our telemetering and with the ground equipment that is measuring velocities at burnout and so forth, we often know within an hour or so whether the missile has performed in accordance with what was planned.

But sometimes a telemetering channel goes out, or else one of our ground tracking stations goes out at the wrong time and we don't get the velocity at burnout. In that case it takes us longer to correlate the great quantity of data that comes in from down range stations with that collected at the launch base. We have, of course, both optical and telemetering data.

This is the reason it is sometimes hard to give a quick answer on a particular launching. I am not trying to avoid answering questions here this morning about yesterday's flight, but I just cannot tell you at the moment whether we got from it all the performance that we wanted.

Mr. KEATING. Would you know in 3 days, if you were ever going to know, whether the missile had returned to the earth's surface at about the point you anticipated?

General SCHRIEVER. Yes; we should know by then.

Mr. KEATING. Do you look upon outer space as simply an extension of atmosphere, as an area different in kind from the atmosphere immediately above us here?

General SCHRIEVER. I think it is quite different.

Mr. KEATING. There have been two suggestions made to us, namely, that outer space as compared to the atmosphere immediately above the earth is rather like the sea with varying degrees of density that is one concept.

The other is that it is more like the difference between land and sea. Where do you think the fact lies, or is it somewhere in between?

General SCHRIEVER. I have not tried to draw a line of distinction in quite that way. From my viewpoint, as a military man, I have looked at space in this way: From a technological and biological standpoint, and from an operational mission point of view, to go from the higher atmosphere in which the Air Force now operates into outer space is quite a natural and normal transition.

I do not mean to suggest that I am thereby claiming all of the missions in space for the Air Force. But a man who operates at

60,000 feet in an airplane is in a region that is on the threshhold of space.

He is then in an environment that comes pretty close to space environment and many of the problems biologically that you would have to lick for him are the same kind of problems you must lick for a man who is to go completely outside the atmosphere.

Mr. KEATING. You get up to a point where your equipment is no longer air breathing equipment?

General SCHRIEVER. That is right.

Mr. KEATING. Something around 60,000 feet?

General SCHRIEVER. That is true. One of our biggest development problems is that to conquer space we are going to have to develop a means of propulsion which will have long endurance and can operate in space.

Our present chemical powerplants are not suited for that purpose, but open to us now are a number of different approaches—nuclear rockets, ion rockets, solar rockets. I expect we shall try them all in our search for an engine that will operate in space for extended periods.

Mr. KEATING. What is the practical likelihood that we can, in the future, transport men and materials in capsules, like we would shoot a missile, more economically than we can fly them through the air from one place to another?

General SCHRIEVER. I believe this is entirely feasible and that it will come. I think that the first real practical use of space flight will be space flight within the earth's gravitational field.

In other words, you will take off from one point and land at another point on earth, using recovery techniques which still need to be developed. We can hardly afford to throw away an engine every time we do this.

But there are ways in which the problems can be solved. These developments will be coming along. I think we will be moving people and things through space and not have to contend with all the problems of moving at high speeds in the earth's atmosphere. The technical problems become very, very great when you move from twice the speed of sound to three times the speed of sound. When you encounter the material problems, heat problems, and so forth, you are really approaching the end of the line.

Mr. KEATING. When do you think I would be able to step into a capsule here in Washington and land in Europe in 30 minutes?

General SCHRIEVER. This is a hard prediction to make, but I see no reason why this should not be possible within the next 15 or 20 years.

Mr. KEATING. Well, that gives me time enough.

The CHAIRMAN. General, some of our missiles are based upon breathing, are they not?

General SCHRIEVER. Air breathing engines?

The CHAIRMAN. Yes.

General SCHRIEVER. Yes, sir?

The CHAIRMAN. How fast can they go?

General SCHRIEVER. The only intercontinental missile we have in this category is subsonic. It flies at less than the speed of sound.

The CHAIRMAN. How fast is that?

General SCHRIEVER. It is in the order of Mach .9, about 600 miles per hour.

The CHAIRMAN. From the military angle, what is the feasibility now?

General SCHRIEVER. Sir?

The CHAIRMAN. From the military angle, what would be the feasibility of that weapon now?

General SCHRIEVER. You mean its operational worth?

The CHAIRMAN. How effective would it be from the military angle?

General SCHRIEVER. This is a matter of judgment, sir. Certainly it is in the same category as our present bombers. I think that our bombers are perhaps a little more effective than the missile, because they have the man in them, because we can carry electronic countermeasures, things of that nature.

The CHAIRMAN. Do you have wing-flown missiles, too?

General SCHRIEVER. Yes, sir.

The CHAIRMAN. Are they pretty much of the same speed?

General SCHRIEVER. We have air defense wing flown missiles that are a little faster than that. The Bomarc flies at almost three times the speed of sound, which is 1,500 miles an hour, or thereabouts.

The CHAIRMAN. What will be the speed of the intercontinental ballistic missile when it is perfected?

General SCHRIEVER. The highest velocity it reaches at the time it enters the atmosphere is about 24 times the speed of sound—that is, about 15 to 16 thousand miles per hour.

The CHAIRMAN. Are there any further questions?

Mr. BROOKS. Mr. Chairman?

The CHAIRMAN. Mr. Brooks.

Mr. BROOKS. I would like to ask you this, General, before you get away: When was the atomic breakthrough?

General SCHRIEVER. Thermonuclear?

Mr. BROOKS. Yes.

General SCHRIEVER. There were two things that really happened that put a completely different light on the long-range ballistic missile.

First was the thermonuclear shot in the Pacific, the Mike shot. This was in 1952. That was the first thermonuclear explosion.

Of course, this was a device that weighed about 60,000 pounds, or in that order, certainly not something you could use in a ballistic missile.

But we fortunately had in the Scientific Advisory Board of the Air Force people like Dr. Teller, Dr. von Neumann. In 1953 we set up a panel and asked these experts and others to give us the best prediction they could with respect to the weight and yield relationship of the nuclear warhead out into the periods of 1959 and 1960.

This panel submitted to us a report in the summer of 1953. Among its members were Dr. Bradbury and Dr. York, for example. The panel predicted that we could get relatively high yields with very low weights in the 1959–60 time period. This prediction completely changed the picture regarding the ballistic missile, because from then on we could consider a relatively low weight package for payload purposes.

Mr. BROOKS. That is really one thing that held up the development of the intercontinental ballistic missile, but when the breakthrough occurred, did we take full advantage of that fact?

General SCHRIEVER. I think in retrospect you might say that perhaps we could have moved a little faster.

Actually, we got this prediction in the summer of 1953. Early in the fall of 1953 Mr. Gardner, who was then with the Air Force, set up a Strategic Missiles Evaluation Committee which reviewed all of the Air Force long-range missiles—not just ballistic. They recommended to the Air Force in February of 1954 that in view of this thermonuclear breakthrough, we should give the highest priority to the development of ballistic missiles and take advantage of the much lighter warhead then possible. This we did.

We picked up the program in March of 1954 and we have been pursuing it on the highest priority ever since.

Mr. BROOKS. It looks to me as though from your own statements, you wasted a year and a half before a decision was made to give this priority.

General SCHRIEVER. I am not sure whether you can call it wasting a year and a half. It takes time to get enlightened evaluation of such complex things. You could not simply take the word of one individual who would say, "Well, in 1960 we will have such and such."

You have to get more people who are also qualified to study these things. There were a lot of people who did not agree with this prediction, plenty of them.

You have to have pretty solid foundation before you launch forward into a multibillion dollar program.

I think we moved reasonably fast, sir.

Mr. BROOKS. It seems to me, though, that if the breakthrough occurred in 1952, and here it is 1958 before we have really taken advantage of it, we have been a little bit tardy about it.

But let me ask you this in reference to the missile that you fired yesterday. Was that capable of carrying an atomic weapon?

General SCHRIEVER. I think I had better not answer that for security reasons.

Mr. BROOKS. Use your judgment if you think it involves classified information.

The CHAIRMAN. We do not want any classified information.

General SCHRIEVER. I am afraid I should not answer that, sir.

Mr. BROOKS. Let me ask you this question. The Russians have fired the ICBM, but actually have we fired more ICBM's than the Russians?

General SCHRIEVER. At least with respect to firings which they have announced we have, yes, but as you know, our Atlas firings to date have been with the boosters only, so they have been at limited range. We will initiate long-range firings this year with the Atlas.

Mr. BROOKS. Of course, the Russians have a regular setup there, a range and all. They must have failed in some of their endeavors, otherwise it would not be necessary to have a setup like they have in Russia. Is that not right?

General SCHRIEVER. That is right.

Mr. BROOKS. What is the average cost of a missile like the one you fired yesterday?

General SCHRIEVER. It is hard to put an exact price tag on it during the development program, but I will give you essentially what they will cost when they go into operational force.

A Thor will cost slightly less than a million dollars each. That is the type that was fired yesterday.

Mr. BROOKS. That simply is in the construction of the missile itself?

General SCHRIEVER. That is right.

Mr. BROOKS. That is after you deduct all the expenses in connection with scientific experimentation and developing?

General SCHRIEVER. I have deducted the cost of constructing the research and development facilities and the cost associated with carrying on the research and development program. I am talking now about the production of the missile and the cost of all of the equipment that goes into it.

It would be a little less than a million dollars when the missiles are introduced into the force.

Mr. BROOKS. That is about the same for the satellite missile, is it not, or is that more expensive?

General SCHRIEVER. Which satellite?

Mr. BROOKS. Let us say Jupiter-C.

General SCHRIEVER. The Jupiter-C, of course, is a research and development article and the Jupiter-C, if you produced in quantity, would cost less than that. The Jupiter itself is essentially the same as the Thor. They are in the same price category.

Mr. BROOKS. So you have gotten out of the experimental stage with the type of missile you used yesterday. Is that a fair statement?

General SCHRIEVER. It is still in the development program.

Mr. BROOKS. It is in the manufacturing stage now, is it not?

General SCHRIEVER. It is being produced on what we call hard tooling; yes. We are not hand-building it. We have the necessary tooling and we are building it on a production line.

Mr. BROOKS. That is fine.

Now, I have one more question. I want to ask you this.

The administration bill provides for a 17 member committee with not less than 1 person from the military. Now, a great many of our witnesses, perhaps most of them, have been connected with the military either directly or indirectly, like Dr. von Braun. He would be military.

General SCHRIEVER. Right.

Mr. BROOKS. Do you not think we might very well place in the bill a stipulation that the first board shall consist of not less, we will say, than 50 per cent military personnel, because the program has been military in the past—let us face it—and then following that there shall be, we will say, not less than 1 military person?

General SCHRIEVER. This is a matter of judgment. My reaction would be that that would not be right. I think that would be too many.

Mr. BROOKS. What would you think would be the right number?

I do not think any member of the committee wants, even by inference, to exclude men like Dr. von Braun if it is in the cards for him to serve on the Board. But if we do not watch out, we may be excluding men that have carried this program right on through to this

hour. Maybe they want to get out later on, but for the time being, unless we have men that have gone along with the program in sufficient supply, the Board will founder for a long time initially. Do you agree on that?

General SCHRIEVER. I agree, but I think a figure of 3 to 5 men, if carefully selected, and they certainly would be, would be adequate.

Mr. BROOKS. Your idea is 3 to 5 men from the Government?

General SCHRIEVER. Yes.

Mr. BROOKS. They might not necessarily be military men, they might be civilian men, but they would come from the United States Government or largely from the Defense Department.

General SCHRIEVER. My 3 to 5 men would be from the Defense Department. I would say that you ought to have at least 2 or 3 in uniform in that group.

Mr. BROOKS. I would think you would want 1 or 2 perhaps from the Weather Bureau because that is important.

General SCHRIEVER. I am not excluding other Government agencies. I have referred only to the Department of Defense.

Mr. BROOKS. If we wished to acquire someone else from other departments, it would have to be in addition to them?

General SCHRIEVER. Yes, sir.

Mr. BROOKS. That is all.

The CHAIRMAN. Could you not depend upon the President to use judgment in making these appointments?

General SCHRIEVER. I think so. I think you could.

But you asked my opinion, and I think that is how many from the Defense Department should be on the Board. I think it is extremely important in the initial phases that there be adequate representation from the military because right now the Defense Department has the only program that exists in the space business.

Mr. BROOKS. My point was that we did not want to write into the bill something that gave the impression that we did not expect more than one man from the military.

That is all.

The CHAIRMAN. Mr. Feldman.

Mr. FELDMAN. General, the proposed legislation calls for a 17-man Board that is to meet no less than 4 times a year. This Board is an Advisory Board. As the name itself indicates, an advisory board is created for the purpose of advising.

Now, liaison committee, or a liaison group, is established for the purpose of coordinating, that is, to let the right hand know what the left hand is doing. That leads to this question:

Would you say there is a sharp line of distinction or delineation between the two types of functions, one, concerning an advisory board whose primary function is to advise and two, a liaison board whose primary function is to coordinate? Would you agree with that conclusion?

General SCHRIEVER. That is essentially correct; yes, sir.

Mr. FELDMAN. So that a board which would meet no less than 4 times a year or even 10 times a year would not be in constant touch with the developments going on or the problems arising in connection with the new agency and the military. Is that not correct?

Let us put it another way. Assuming you had 3 or 5 or 7 members from the military on an advisory board that met 6 times a year, would

they be able to perform adequately the liaison functions that go on in the every-day work between two groups that are supposed to be working in cooperation with each other?

General SCHRIEVER. I would doubt that they could perform it adequately. In the first place, they would be at too high a level in the military to do what you are talking about.

Mr. FELDMAN. An advisory board, even if it had more power than the particular Advisory Board proposed in the new legislation, could do no more than set policy. Is that right? That is what it is created for when it is on that kind of high level, is that not so?

General SCHRIEVER. That is generally correct; yes.

Mr. FELDMAN. And the every-day problems that come up between two agencies could only be handled properly by a liaison group which would have some means of constant coordination?

General SCHRIEVER. I'd judge that is the most effective way.

Mr. FELDMAN. That, to my mind, is the only way that the right hand can know what the left hand is doing.

General SCHRIEVER. That is the most effective way I know of to do it.

Mr. FELDMAN. In other words, you pointed out earlier in your testimony, in response to a question by Congressman Natcher, that the military must carry out its portion of the program.

General SCHRIEVER. Yes.

Mr. FELDMAN. And the way they can do that best, of course, is through close liaison with any new agency?

General SCHRIEVER. Yes.

Mr. FELDMAN. Krafft Ehricke, who was a witness here yesterday, as Congressman Fulton stated before, said that Russia was too far north for a good moon shot. What are your views concerning the location of our base in Florida?

General SCHRIEVER. Our base in Florida is so situated geographically that it can accommodate a moon shot.

Mr. FELDMAN. Do you have any comments in connection with Mr. Ehricke's observation?

General SCHRIEVER. No; I will have to look into that. That is the first time I have heard that statement made. I do not understand why it should be, but that intrigues me. I shall have to look into it. I hope he is right.

Mr. FELDMAN. So do we.

Astronautically, when is the moon in a good position for a moon shot?

General SCHRIEVER. I cannot give you that detail, but it happens over a period of about 3 or 4 days each month as far as our location down south is concerned. I do not have the astronomical details, but that is the case.

The limiting reason is, of course, the ability to make an observation as to whether you have accomplished what you are after.

You could shoot at the moon any time, but you might not be in a position to see whether you made it. It is observing what happens at the other end that is important.

Mr. FELDMAN. Early in your testimony you spoke of a conference you had with some scientists and you mentioned Dr. Killian and several others who, prior to this proposal concerning the NACA or the NASA, had mentioned the need for an agency with a singleness of purpose

to explore and work in outer space. You said that you were in agreement with this point of view.

General SCHRIEVER. I made that statement. It was not a conference. It was an informal meeting at which we were discussing certain problems concerning organization, looking into the future. I was in agreement that all of the development, research and exploration into space should not be left in the hands of the military alone.

In my opinion, you need a scientific group that pushes forward on the broad frontiers of knowledge as well. I want to make it real clear that I believe very, very strongly that the military must not be inhibited in carrying out their own program.

Mr. FELDMAN. I will not attempt to speak for this committee, but I know the chairman previously indicated that that was one of the things the committee had uppermost in their minds.

However, at the time of this informal discussion, did not the scientists have in mind concentrating on the development of a program that would deal with outer space?

General SCHRIEVER. Yes; during that discussion there was absolutely no inference that this agency should be the single agency to do all of the space work. The general point was the need for a scientific approach to the space problem. The discussion is largely scientific in nature.

Mr. FELDMAN. There is so much overlapping anyway between both the civilian and the military that there would have to be the kind of coordination you are talking about.

General SCHRIEVER. That is right.

Mr. FELDMAN. And the kind of emphasis?

General SCHRIEVER. Right.

Mr. FELDMAN. But it was the purpose of these scientists to concentrate on outer space problems. Is that right?

General SCHRIEVER. Largely from the scientific point of view, and to undertake things that might look screwball in nature, or that the military cannot undertake—things that are real researchy in the sense that if the military did them we would be criticized. We might not even think of them, maybe.

Mr. FELDMAN. Do you think that the kind of group thinking of the present NACA setup, at least as evidenced here, would carry out a program of that kind? Because Dr. Dryden characterized a lot of these ideas as circus shots and things of that sort, and was very wary of even thinking along those lines.

General SCHRIEVER. Words are hard taskmasters. There certainly are things that you should not do.

Let me speak of my experience with NACA. I attended Stanford University and took graduate work there just before the war. Some of the finest students from Stanford in the aeronautics field went to the NACA at Moffett Field. They stayed there for a good many years.

Only recently a couple of them left to go back as professors at Stanford University. I have found that NACA has a lot of forward-looking, imaginative people.

Mr. FELDMAN. Among their 7,500 or 8,000 employees I am sure they have many that are very forward looking, but I just wondered whether thinking in terms of aerodynamics, as distinguished from astronautics——

General SCHRIEVER. I think you have to get some new blood, say astronautics blood, into the organization, certainly.

Mr. FELDMAN. And that these scientists had in mind concentrating on that field at this informal conference you are talking about?

General SCHRIEVER. Yes.

Mr. FELDMAN. Do you think that an agency such as the NACA that has been primarily concerned with aerodynamics can suddenly switch over to thinking in terms of astronautics? It is a question of emphasis now.

General SCHRIEVER. Yes, I do. I think you have to organize in a fashion. I ran into the same problems in reorganizing my staff. If I subordinate, say, the space vehicle part to the Atlas program, I am not going to get the emphasis I want on the space vehicle.

I have organized in such a fashion that a separate element in my organization spends all their energies on the problems of space vehicles as distinct from those of the ballistic missiles.

Talking now philosophically, I think you can approach the organization problem in the same way within the NACA.

Mr. FELDMAN. Are you building on a block as you put it before, or should you start with a fresh point of view?

General SCHRIEVER. It is a matter of judgment. My own judgment is that you should use the NACA as the building block.

Mr. FELDMAN. Earlier, you were asked your views about the proposal that Dr. von Braun made here that a man be sent into space in a rocket, going up 150 miles in a capsule and returning to earth. It was also mentioned that Dr. Dryden characterized that kind of experiment as similar to a woman being shot from a cannon at a circus.

That was kind of lifted out of its context a little bit, because General Medaris pointed out that you have to crawl before you walk and that there was a great deal of scientific value to such an experiment or there could be.

I think it would be unfair to Dr. Dryden to give a curbstone opinion under those circumstances, and also to, at the same time, have him characterize the program as one that was circus-like. It was equally unfair, of course, to Von Braun, because I am sure, when he gave that testimony, he was thinking in the same terms that General Medaris was and knew a great deal more than just the fact that we wanted to get a man up into space in time for the purpose of putting on an exhibit.

Do you have any views on that?

General SCHRIEVER. I think there is no question but that you could get a lot of data from such a flight.

At the same time, I would not want to say that this experiment is one that I would propose. There are a number of proposals for getting man into space. I know that ARPA is considering these proposals and that undoubtedly a sensible program will be gotten underway.

As a matter of fact, certain things in programs now underway will contribute toward this end. Also, you certainly cannot overlook the psychological and political aspects of perhaps getting someone up in space, even if it does come close to appearing to be an exhibition rather than a scientific event.

I would not go along 100 percent with what Dr. Dryden said, and I am sure he did not quite mean that 100 percent the way it has been taken.

Mr. McDONOUGH. Speaking on that particular subject about shooting a man into space 150 miles, first, has that been a serious subject for discussion under your command?

General SCHRIEVER. Not that type of experiment.

Mr. McDONOUGH. The X 15 is, I suppose?

General SCHRIEVER. The X 15 is, although the X 15 is not directly under my supervision. We have developed a complete step-by-step program for getting man into space on a phase basis involving recovery capsules, animals, and so forth. We think this systematic, long-range approach makes a lot of sense, and we hope to get some approval for.

Mr. McDONOUGH. Certainly, shooting a man 150 miles into the air and returning him is not a stunt, by any means. You have the reentry problem, you have the ability of the man to stay under pressure in the takeoff, his condition up there, coming back, and his landing.

It is not a stunt, in my opinion, at all.

Do you have any volunteers who are willing to go on such a flight?

General SCHRIEVER. I am sure that there are plenty of volunteers. We have gotten quite a few letters from volunteers.

Mr. BROOKS. I will say that I have gotten a letter, myself.

Mr. KEATING. They told me at Canaveral that they had 13 or 14 from the Army. I bet they got just as many as that from the Air Force.

Mr. McDONOUGH. Seriously, do you have men that you can say would be willing to go if we were ready to shoot one in 30 days?

General SCHRIEVER. We have heard from a number of people volunteering to be the first man in space. I got one letter from an Australian recently and it was a very sensible letter. He was a young man who was volunteering. It was a very well written letter. He was not a crackpot.

Mr. McDONOUGH. Whether it be a capsule or powered vehicle, we have a man who is willing to fly the X 15 and we know him.

General SCHRIEVER. That is right.

Mr. McDONOUGH. How far has Pied Piper progressed?

General SCHRIEVER. This is a highly classified program, sir. I would say that it is progressing well. It is now on a high priority, that is, on a priority equal to that of the ballistic missiles.

Mr. McDONOUGH. It is being designed for power flight?

General SCHRIEVER. No, sir. This will be a satellite.

Mr. McDONOUGH. It would just travel on an orbit?

General SCHRIEVER. Yes, sir.

Mr. McDONOUGH. And be capable of reentry?

General SCHRIEVER. Not necessarily. But we are very interested in the reentry of capsules. It is part of our development work.

Mr. BROOKS (presiding). Mr. Metcalf.

Mr. METCALF. I was interested in your designation of some of the research as screwball. I hope you will clarify that a little bit because I think you meant it in somewhat the same sense that Dr. Dryden meant, this business of shooting a man into space as a stunt. That

would be the basic research for which there would be no immediate military or civilian value, would it not?

General SCHRIEVER. My reference here was to research that might look screwball to some people. That does not necessarily make it screwball.

Mr. METCALF. Would you call something like a proposal for photon propulsion screwball?

General SCHRIEVER. No, I certainly would not.

Mr. METCALF. In your experience, has there been some actual military or civilian value derived from research that looked very strange in the past?

General SCHRIEVER. I think you have me there. I cannot quote any examples, but we do carry out basic research programs in which large funds are not at stake and which do not have immediate military application, although they are directed toward a possibly useful military application.

In other words, if we are successful in this type of research, it can lead to worthwhile military application. I believe we should have people carrying out research who have no thought about the military whatsoever.

Mr. METCALF. People who probably have not gone through the same sort of program as the military, so they are not thinking along the same lines as you.

General SCHRIEVER. That is right, a military man does go through a regime that is quite different from a scientist.

Mr. METCALF. All these research agencies under the proposed legislation would be under the NASA. Would you not feel that that is the way it would be set up?

General SCHRIEVER. Yes, although I think it should be clear that we in the military do a lot of research and development and experimental work which is necessary for the actual development of the weapons themselves. We would continue to do certain research and development work as we now do in the airplane field.

Mr. METCALF. Where, in such a system, would be a lunar probe? Would it remain under ARPA, would it go to the new NASA or would it be purely military?

General SCHRIEVER. I would say that if the agency already were in existence the lunar probe might well be undertaken by that Agency. That Agency would still have to draw upon our equipment and our resources and, therefore, as was pointed out earlier, there would have to be the closest liaison between it and the military.

Mr. METCALF. I think it has been developed by Mr. Feldman that no matter what happens to the composition of the board there has to be daily, constant, and continuous liaison between the civilian and the military agencies.

General SCHRIEVER. I think so.

Mr. METCALF. Would you just let ARPA continue on this project for a lunar probe, or would you transfer that over to the new agency?

General SCHRIEVER. I would leave it where it is.

Mr. METCALF. And just incorporate that within it?

General SCHRIEVER. I mean that any time you start transferring things in midstream, you just have a built-in delay. That is all there is to it.

Mr. METCALF. I think that is all.

Mr. FELDMAN. I have 1 or 2 last questions, General Schriever.

In the development of the missile and satellites and the whole program regarding outer space, there will be a great deal of contracting work where there will be a shift in emphasis from, say, aerodynamics, to hardware that will travel in outer space.

General SCHRIEVER. As I take it in the proposed legislation, this would be the case.

Mr. FELDMAN. Is it not the case, too, in the present program of the military?

General SCHRIEVER. You mean our emphasis in this direction?

Mr. FELDMAN. Yes.

General SCHRIEVEV. Yes, there has been.

Mr. FELDMAN. A lot of engineering into new contracts?

General SCHRIEVER. Yes.

Mr. FELDMAN. That is a changeover from one type of industry to another type of industry. Is that right?

General SCHRIEVER. That is not right. When we held our contractor-selection competitions for our present ballistic missiles and satellite programs, it turned out that the companies which had been engaged in aircraft weapon development were among the most competent companies in the country for undertaking this new work.

Mr. FELDMAN. But during the changeover there was an interim period when you had to kind of let down on the emphasis of making aircraft and things of that sort and going into this new field. Is that right?

General SCHRIEVER. I do not think we have let down the emphasis.

Mr. FELDMAN. Was there not a dislocation caused by the shift, which caused a certain amount of unemployment, say, in the main plant and various other plants? Is that right?

General SCHRIEVER. This is correct, but you cannot pinpoint space——

Mr. FELDMAN. I am not finding fault; I am just pointing out the fact that we are going through a transitional change.

General SCHRIEVER. That is true because missiles, particularly in the air defense field, have developed to a point where they are beginning to dislocate the aircraft industry in the fighter-interceptor area, for example.

Mr. FELDMAN. After the development stage in missilery, and when we get into the making of hardware for missilery and satellites and space ships and so on, the unemployment caused by this dislocation, that slack, will be taken up again. Is that not so?

General SCHRIEVER. If you measure total labor requirements on the basis of the dollars required for the program, this is certainly true, because I do not foresee that the sums required to carry out these new programs will be less than for those of the past.

Mr. FELDMAN. While at the present time we may have some unemployment partially caused by this dislocation, when this program gets into full swing would it, in your opinion, absorb most of the people that were previously engaged in the aircraft industry and who are unemployed at the moment and who will be again reemployed in this new field?

General SCHRIEVER. I think, numberwise, this is probably correct, but I certainly would not want to say that it would be true in every specific location or company.

Mr. FELDMAN. It certainly would be a trend, to say the least.

General SCHRIEVER. I think so; yes.

Mr. FELDMAN. We might even get to a point where we will have a shortage of labor in 3 or 4 years.

General SCHRIEVER. I might cite one example. Lockheed has put their missile division in the San Francisco area. There is a labor shortage there, of the kind of people they need.

Mr. FELDMAN. I am trying to bring out the fact that the impact of this new program on our economy can be a great one and can absorb a great deal of unemployment.

General SCHRIEVER. Yes; we have in our ballistic missile program alone—in our prime contractor plants and in our first-tier subcontractors—about 80,000 employees.

Mr. FELDMAN. Can you give us an idea of what it was 3 years ago?

General SCHRIEVER. Three and a half years ago we only had two contractors, North American and Convair, and a few minor subcontractors. I don't think we had over 5,000 people.

Mr. FELDMAN. In other words, it is multiplied geometrically rather than arithmetically?

General SCHRIEVER. Of course, the work is spread out throughout the country, too. We have a number of contractors on the east coast, and in the Middle West.

Mr. McDONOUGH. Will the gentleman yield at that point?

Mr. FELDMAN. Yes.

Mr. McDONOUGH. Are these contractors you are speaking about engaged in the production of hardware or development and research?

General SCHRIEVER. Development and production.

Mr. McDONOUGH. And, between the two, which field are most people employed in?

General SCHRIEVER. Up until recently, we have emphasized the engineering and development phase of the program, but these same contractors are continuing into the production phase of the program.

Mr. McDONOUGH. Up to what point do you call in the contractor? Are you producing anything at all?

General SCHRIEVER. You mean as a Government agency?

Mr. McDONOUGH. Yes.

General SCHRIEVER. No, sir.

Mr. McDONOUGH. You are merely asking for proposals and submitting specifications to be met.

General SCHRIEVER. That is right, but that is a continuous process in these programs. Of course, we do provide a lot of the facilities for the testing by which we evaluate developments as they progress.

Mr. McDONOUGH. Is there any testing being made by private industry, independent of the military, on these matters?

General SCHRIEVER. In the missile area?

Mr. McDONOUGH. Yes, missile or astronautics?

General SCHRIEVER. There is some research and experimental work being done within some laboratories on their own. This is always true in major development programs, but does not involve large-scale and expensive testing. Such testing is all done under Government contract.

Mr. McDONOUGH. Is the Point Mugu base under your command?

General SCHRIEVER. No, Point Mugu is the Pacific missile test range. It is under the control of the Navy and under direct Navy command, but it is a joint range.

These facilities are available to us, although we don't use them. We have no missile for which it is suitable, but the range will support our firings from Cooke Air Force Base.

We are not putting up a separate facility for firings we will do from California.

Mr. McDONOUGH. In other words, there will be no duplication?

General SCHRIEVER. No duplication. They will support us in these firings.

Mr. McDONOUGH. Is there a reduction in duplication in actual testing, for instance, between Cape Canaveral, Point Mugu, and Edwards Air Force Base and those places?

General SCHRIEVER. Canaveral is the only instrumented, long range that we have in being today.

All three services use Canaveral, and they use the same instrumentation. For example, at the time that the Air Force and Army initiated Thor and Jupiter programs, we coordinated with the Army and Patrick to establish the instrumentation requirements for our test programs.

So I would say that Cape Canaveral, although it is under Air Force management, is a Department of Defense range.

Mr. McDONOUGH. And the duplication of testing is reduced to a minimum; an effort is being made to reduce it to a minimum?

General SCHRIEVER. Duplication of testing?

Mr. McDONOUGH. You are not going to test a missile at Mugu that you could test at Canaveral?

General SCHRIEVER. No. We will not be testing missiles on the Pacific range.

The actual firing of missiles at Cooke Air Force Base, for example, will be for training and for operational suitability testing, not for development testing. Development testing will all be done at Cape Canaveral.

Mr. McDONOUGH. What I am getting at is this. When we set up a budget here we do not want to have an expenditure of several million dollars in 2 places when it can be done in 1 place.

General SCHRIEVER. This is very closely watched at the Department of Defense level to insure complete coordination between the military departments regarding range utilization.

Mr. McDONOUGH. As a military commander engaged in the defense of this Nation, what is your opinion as to entering into some agreement with other nations to establish outer space, that is beyond the thousand-mile level, as a peace area, rather than a military area?

General SCHRIEVER. I think if this could be accomplished, it would be very good.

Mr. McDONOUGH. Do you conceive it to be in the same position as where we look upon the ocean as an open highway for all nations, but at the same time we must protect our interests on that highway at all times?

General SCHRIEVER. That is the way I look at it, yes.

Mr. McDONOUGH. You mean, if we did enter into an international agreement with other nations, especially with the one that

seems most capable of attacking us in that area, Russia, that it would be with the understanding while it is for peaceful purposes, nevertheless, we will protect our interests in that area at all times?

General SCHRIEVER. As a practical man I think this is what we have to do.

Mr. McDONOUGH. That is all.

Mr. BROOKS. Mr. Fulton?

Mr. FULTON. General, I would like to ask you about your ideas as to the method of industrial development of this new space or guided missile industry.

When the contractors are large contractors making agreements for overall projects, does that let every type of business take a part in the contracting with the military procurement agency, or does the subcontracting go down pretty deep through the ordinary people that that particular contractor has used previously?

How wide a spread are you getting, both in types of business as well as area cooperation and participation in the expansion of this industrial field?

General SCHRIEVER. I do not have exact figures.

Mr. FULTON. Will you put them in the record at this point.

General SCHRIEVER. Yes; I would rather do it that way, sir.

Mr. FULTON. Thank you.

(The material referred to follows:)

AIR FORCE BALLISTIC MISSILE DIVISION CONTRACTING PROCEDURES

One basic factor must be appreciated in any analysis of industrial development and diversification in the Air Force ballistic-missile program. That factor is the overriding urgency of the program, which has necessitated selection of the best qualified contractors in the country, both managerially and technically, in order to insure development and production within compressed time schedules for the complex systems and components required. No new industry has resulted; in fact, there could not have been time to create a new industrial base.

Development and production of major ballistic-missile subsystems has required extension of the technical state of the art in the structures, propulsion, and electronic portion of the aviation industry. For all intents and purposes, the strongest capabilities for this extension and expansion have been found within existing defense industry. Major contractors have been selected from the industry listing and data long maintained at Headquarters, Air Materiel Command.

The major contractors' make-and-buy structures—which determines the extent of subcontracting—are carefully reviewed by Air Force representatives as part of our contract negotiation, and maximum subcontracting is encouraged. Some of the factors by which these make-and-buy structures are judged are availability of in-being facilities and required technical personnel, distressed labor areas, startup cost, unit cost, etc.

The resultant contractor structure of the Air Force ballistic-missile program includes 18 major contractors, some 250 subcontractors, and thousands of suppliers—all widely dispersed, geographically, across the Nation. Through calendar year 1957, $268.3 million, or about 21 percent, of ballistic-missile business has been subcontracted to small business by major contractors in the program. A small-business representative has been appointed within the Ballistic Missile Office of AMC, the office in our Inglewood complex which is responsible for industrial contract administration. As an example, the Douglas Co. is currently utilizing 8,473 small-business concerns as subcontractors in producing the Thor missile.

With the advent of Sputnik I and II, security classification has been relaxed to some degree, allowing wider dissemination of our programs to industry and the Nation in general. All participating prime contractors have been instructed to provide information on their respective programs to companies desiring to participate, providing they have been given security clearance and have a need

to know. Procedures have been established for providing the required security clearance. In addition, speeches are frequently made to industrial groups by military representatives of the ballistic-missile programs, and our headquarters is visited monthly by dozens of prospective contractors.

Mr. FULTON. Some of us are interested in developing this field because we think this is the equivalent of the start of the automobile, the telephone, the telegraph, or the airplane industry. We feel that it is a bright, new field for industry and, if more companies knew about it, there would be a tremendously accelerated interest and pace in development. Do you not agree, sir?

General SCHRIEVER. I think most industry does know about this, because we certainly are getting a tremendous amount of interest and requests from industries throughout the country to enter into certain aspects of the program.

Mr. FULTON. My judgment is, and I said it to the General Counsel this morning, that most industry does not know about it. In the fields in which you and the Air Force have been dealing with, I think that is true, but, out in the general area of basic industry and fabricating industry, they do not know what is going on in this particular field.

General SCHRIEVER. This is industry that has not worked for the military departments previously?

Mr. FULTON. Yes.

General SCHRIEVER. I think you are probably right, Mr. Fulton.

Mr. FULTON. I have suggested to the General Counsel that we, in this committee, have mobilization of industry meetings, have a separate space and guided-missile section and program. Would you agree on that? There are now regional meetings being held, with the War College participating, on organizing industry for what might be the next trouble.

Do you not think there should be added emphasis on the space field in that particular program?

General SCHRIEVER. Yes. I would think anything that would stimulate industry and the people more and give them more knowledge would certainly be a step in the right direction.

Mr. FULTON. Do you think it would be wise for the Government to explain, possibly through the Department of Commerce, to the people some of the testimony that we have had before this committee, so that the industries, themselves, will know what the developments are and can aim in that direction?

General SCHRIEVER. I think that would be a good idea; yes, sir.

Mr. FULTON. Do you likewise feel that there is need for an authoritative governmental overall glossary and dictionary of the scientific terms in the space and missile field? Should we have an agency set up that will take part in this program on the basis of coming up with all the services, all the Government agencies and contractors, and getting a terminology that is authoritative?

General SCHRIEVER. I think this would be helpful.

Mr. FULTON. As you know, the Air Force has its glossary of March 1958, but that is the Air Force's glossary, and is not an official terminology so far as the overall United States Government is concerned. So that we do need a broader dictionary or glossary, do we not?

General SCHRIEVER. I think this would be helpful. This is something I had not thought about, myself.

Mr. FULTON. With respect to the translation of materials from foreign countries, do you not think it would be advisable, under some sort of agency or department in the Library of Congress, possibly the Legislative Reference Service—we have a very prominent member, Dr. Charles Sheldon, on this consulting staff of ours—to have a program of getting an overall translating service on a broad scale of the many facets of basic research and development in the applied-science field on space technology?

General SCHRIEVER. I am not too familiar with the translation activity that is going on, although it has come to my attention from time to time that, perhaps, it is not quite as adequate as it should be.

Mr. FULTON. When that translation is made, there should be adequate facilities made available by the Government so that they will be ready for use by the various services and by the companies in the field?

General SCHRIEVER. Yes.

Mr. FULTON. For example, it has been said that small companies cannot get hold of the research programs because they have not had previous contracts. Nor can they get the information on certain technical developments, because they have not been previously in the contracting field with a particular service. So, what happens is this: When they are not able to get the information ahead of time, they are automatically excluded from participating. Do you think that should be cured?

General SCHRIEVER. I do not believe that is entirely correct. It is correct that companies who are not participating in a program do not have clearance, securitywise, to receive classified information about that program.

Mr. FULTON. That is my point. First, you do not have the clearance, so you do not get the classified information because you are not participating in the program. That is the reason you cannot participate in it, because you do not know about it ahead of time. So, it automatically restricts it to the people who are, primarily, participating in the program.

General SCHRIEVER. The people who are already participating in it have certain advantages. There is no question about that. The fact that they are already participating and have an organization and have experience and background——

Mr. FULTON. How do we broaden it so that other, smaller companies can now participate? Could they possibly, be cleared ahead of time so that they can get access to classified information that will let them know what is going on?

General SCHRIEVER. This is a very difficult problem. You could go too far in one direction and give information to everybody. The security problem is one that I do not quite have the answer to.

Mr. BROOKS. Will the gentleman yield at that point?

Mr. FULTON. Yes.

Mr. BROOKS. Last week, at my home, there was a meeting, an industrial meeting, held by the Small Business Administration. The Air Force was well represented at that meeting. So was the Army, and so were some other branches of the services. The question of bids on contracts and offerings and all that sort of thing was covered pretty well. There might have been more emphasis placed on ballistic missiles and aerodynamics, and things of that sort. Would you agree to that?

General SCHRIEVER. I am sure there probably was.

I would also say, however, that in the contractor selection competition, no company is automatically excluded just because it does not happen to have a security clearance or are not participating in the program.

Mr. BROOKS. The point I am getting to is this: that these small-business men should be invited to these types of meetings. When they are invited, they should be given the means whereby they can contact the proper Government officials and get proper notice and opportunity to present their offers, if they wish to do so.

General SCHRIEVER. I think there is a great deal of potential for small business through contracts directly with the Government in the research and development area.

I certainly agree with you, Mr. Fulton. It would be highly desirable if we could find the right platform.

Mr. BROOKS. Would you agree with me, too, that there might be more emphasis placed on these industrial meetings?

General SCHRIEVER. Yes.

Mr. FULTON. That was my original suggestion. He agrees with both of us.

May we finish on that?

Here is one practical result and there is no complaint because these are high-type businessmen.

The small-business man finds that he learns of something being done, often at Cape Canaveral, after the fact.

There is a small business of medium size in Pittsburgh that had the design for the type of structure, steel structure, that encloses the missile. It found, after the fact had occurred, that somebody, through another contractor, had simply ordered the installation from the West at a great cost of freight on the same design that the Pittsburgh company had developed and worked out at its own expense, but had not patented.

The Pittsburgh company had been given no opportunity to bid on its own item and it was brought 3,000 miles across the country to Cape Canaveral with no notice to the Pittsburgh company.

Now, how do medium-size companies get into the program and get the chance to bid through your prime contractors?

Is it not working now so that the prime contractor gets the contract and he then deals on a commercial basis with whomever he wishes.

General SCHRIEVER. No, I certainly do not think that is true. These people are not directly under my control, though.

Mr. FULTON. I agree on that.

General SCHRIEVER. We have Air Force plant representatives at our major contractors. They very closely screen and scrutinize the subcontracting activity of each of these major contractors.

Mr. FULTON. May I just finish with this?

May I have the head of the Small Business Administration contact you and work out with you a program that can be recommended to this committee by a joint statement of the two of you as to how small business and medium-size businesses should best participate in the space and guided missile production program?

General SCHRIEVER. I will be very happy to have him come out and meet with both myself and General Funk, who is the air materiel command officer out there, who is responsible for all the contracting and

who is going to appear before the Senate Small Business Committee here next week, I think.

We shall be very happy for him to come out.

Mr. FULTON. Thank you.

We would like to have your legislative recommendations on this matter for the committee to put in its legislation.

May I close on one thing that you spoke of, and that was your worry about security. How did Reuters Agency in Britain have the story last weekend and that there was going to be a shot at Cape Canaveral Wednesday, yesterday, of this week, when this committee knew nothing about it?

I checked with several witnesses here that were in a position to know and they did not know about the schedule, and yet, through some leak, Reuters, a foreign news agency, knew about it.

Now, will you please explain that to me through the proper Air Force channels because I mighty well would like to know.

I wanted to go see the shot with other Congressmen and I did not know about it. Yet I could read of it through Reuters.

General SCHRIEVER. I do not know, myself.

Mr. FULTON. Will you please supply that for the record.

General SCHRIEVER. I can assure you I was extremely upset by this story. I do not know where it came from.

Of course the fact that we have a launching scheduled down there is known in the proper channels within the Air Force and Department of Defense. Where a leak might occur it is hard to say.

Mr. FULTON. It was not one of those authoritative sources often quoted in Moscow, was it, that gave the information out to Reuters?

General SCHRIEVER. Not from my organization.

Mr. FULTON. I would not imagine so but, I am just asking you about your security. If it disturbs you very much on that story, how do you think it disturbs Congressmen when we want to see the shot and cannot get anybody to say the shot is going to take place.

I wanted to go down and see it, but I could not get anybody to calendar it for me within a week. I should have believed Reuters of London, I guess.

General SCHRIEVER. Well, this was classified information. In executive session I would have been very happy to give it to you.

Mr. FULTON. How, then, did Reuters get it? I think that should be answered for the records of our committee.

Mr. KEATING. Mr. Chairman, will you yield for a question or two?

They have been having one of these national researchers conferences in my city of Rochester in the last 2 weeks. In opening, they pointed out the very purpose of it was to acquaint the business manufacturers in that general area about new military developments.

Now, they would cover space and such matters in it, insofar as it was unclassified.

General SCHRIEVER. Yes.

Mr. KEATING. You made the statement that 3½ years ago there were roughly 5,000 people engaged in this program and today there are 80,000.

I realize these are rough figures. What do you look for 3½ years from now, again in rough figures?

General SCHRIEVER. If we are talking about the Air Force program alone——

Mr. KEATING. Were you talking about the Air Force program?

General SCHRIEVER. Yes. I would say that there certainly will be some increase, although we have built up very fast and there has been a leveling off in the last 12 months.

I would think that we might increase by another 50 percent.

Mr. KEATING. I assume that a comparable development has taken place and will take place in the other services or perhaps you are not familiar with that.

In general, would that be true?

General SCHRIEVER. This would be difficult for me to say. Do you mean that in the overall missile field there certainly has been and will continue to be an upward trend?

The Army is engaged in its antiballistic missile defense program and in its Pershing missile program; the Navy is active with its Polaris and its air defense missiles programs. These are all on the upward curve in terms of manpower required in industry.

Mr. KEATING. That, so far as you can foresee, will continue in the next month and probably the next few years?

General SCHREIVER. I would say that that trend will continue up for some time.

Mr. KEATING. That is all.

Mr. BROOKS (presiding). Let me ask you this now. In response to the question that Mr. Fulton asked you, would it be possible for you to advise the counsel of our committee the next time there will be a shot by the Air Force at Cape Canaveral so that we can get word to Mr. Fulton and other members who might wish to go?

General SCHRIEVER. Let me try to give you the answer directly. We can give you classified information as to when the next shot will be.

Mr. BROOKS. You can give it to counsel. I was watching an atomic test at one time. I spent a week there and I think the test is yet to go off. It never did go off.

Now, we might run into the same thing, but if members want to go down there and see a missile go aloft and you can do it without violating security, and it seems to me you can, why they should have an opportunity.

General SCHRIEVER. I agree with this.

Mr. BROOKS. I know the general well enough to know he will be glad to cooperate with the committee.

General SCHRIEVER. We have had Members of Congress there, and we are very happy to have you come down, as a matter of fact.

Mr. BROOKS. We are anxious especially to get Mr. Fulton down there. But, the gentleman had better consult counsel before he goes down again.

Mr. FULTON. I will.

Mr. KEATING. May I make a comment before we adjourn. I have been very much impressed with your testimony, General. The same goes for the other representatives of our armed services that have appeared before us.

I wish every American citizen could hear the testimony of gentlemen like you and Admiral Rickover and the others who have told us about this picture, because I feel that it would instill great confidence in the minds of the people and those in responsible positions in our services would have this great problem before them.

I compliment you and I extend the same to the other services that have appeared here. I have been very delighted with the real vigor that you are putting into this program, all of you.

Mr. BROOKS. I am glad Mr. Keating mentioned that because I consider General Schriever a very able officer and I like the way he testified.

Mr. FULTON. I want to say this. How many echelons of decision do you have to go through to get a firm decision on a test?

My criticism at Cape Canaveral was that you could not find who was really going to make the decision on the first test. It did not seem to be there.

Nobody at the local installation seemed to know when it was going off, even within 12 hours before the next countdown started.

How many echelons above you do you have to go through to get a firm decision on a major missile shot?

General SCHRIEVER. None. We make the decisions right within our headquarters.

Mr. FULTON. Has that been the way all along?

General SCHRIEVER. Yes, sir.

Mr. FULTON. How did the Air Force get the first instruction to make shots? Is it just an overall instruction or did they tell you to go ahead on this missile or that missile?

General SCHRIEVER. When we obtain approval to proceed with the development program of a specific missile such as the Atlas or Thor, the actual implementation of that program is then left up to the Air Force. In my particular case I have a very great authority with respect to the management of the programs. The scheduling of tests is based strictly on technical considerations.

When the missile is ready to go, it goes.

Mr. FULTON. I want to congratulate you on your testimony and the Air Force on its progress in the space and missile field and also to say that I do not believe that that was the fact when the Navy was first shooting off the Vanguard.

They did not have at the scientific level the power of firm decision, as to the timing and the method of shot.

General SCHRIEVER. That may be true. For example, when I go down to Patrick I do not run the show down there. The organization is set up and the people that are responsible for the test carry on. I am down there observing.

Mr. BROOKS. General, when you receive authority to make the shot, what are the controlling elements in the delay? For instance, Mr. Fulton was there waiting for that shot. He apparently thought it was going off rather slowly, but you have to move quickly, I can see that, in this business.

What are the controlling, last-minute considerations?

General SCHRIEVER. They are usually technical in nature. We go through quite a long countdown and we check everything before these research and development shots.

Delays are becoming less and less frequent now. As a matter of fact, on the last several shots of the Atlas we have gone through the countdown and pushed the button right on the second.

Mr. BROOKS. I mean, what will stop your countdown? Would it be a change in the weather, a change in wind variance, or something of that sort?

General SCHRIEVER. No, not for our missiles, no. We have no problem on the weather.

Mr. BROOKS. What is it?

General SCHRIEVER. It is usually a technical difficulty. Maybe a telemetering channel goes out, or maybe the range safety radar goes out. Or perhaps we discover a leak in our fuel system somewhere, or in our liquid oxygen system.

Mr. BROOKS. You are not controlled though by last-minute cables from Washington, are you?

General SCHRIEVER. Absolutely not.

Mr. BROOKS. And there are no considerations other than——

General SCHRIEVER. The people who are conducting the test have the responsibility for making the decision as we go along.

Mr. FULTON. You hit a very pertinent point. Suppose you had a liquid oxygen valve that had failed three times, as it did with the Vanguard at Cape Canaveral, and then you were repairing the valve, say the third time, and the decision comes from Washington for you to go ahead with the shot. You know that this particular type of valve has been leaking each time you started your countdown. Would you then go ahead with the shot as ordered, because that is what the Vanguard people had to do?

General SCHRIEVER. If I were directed by higher authority, which I have never been, I would go ahead with it, but I would certainly state that it was against my better judgment.

Mr. FULTON. Thank you.

Mr. BROOKS. Now, if you got outside direction to stop or to send that missile up, it might actually be very dangerous, if you sent a missile up with a mechanical difficulty; is that not true?

General SCHRIEVER. Well, there are certain conditions under which it could be dangerous—not to life—but dangerous to equipment. I think these are hypothetical cases so far as my program is concerned anyway.

Mr. BROOKS. We want to develop these things to the fullest extent. Now, if your missile is in difficulty mechanically, a leak, for instance, then the take off, you say, is not dangerous to property or life at all?

General SCHRIEVER. If there was something mechanically wrong with the missile, it would not be fired.

Mr. BROOKS. Even if you got the word from Washington to fire it?

General SCHRIEVER. That is right.

Mr. BROOKS. You would not fire it?

General SCHRIEVER. I would not fire it.

Mr. BROOKS. So you have real control of the situation down there. If Washington had some reason for holding up the firing and sent you word, there would be no reason for not holding it up, would there?

General SCHRIEVER. If I got the direction not to launch, I would not launch—certainly not.

Mr. BROOKS. Because there is no danger at all, but there might be danger in sending aloft a missile that has mechanical trouble.

General SCHRIEVER. If it was mechanical trouble, we certainly would not launch it, but in Mr. Fulton's example it was a question of judgment whether or not that particular valve would function properly after they had several failures. I am sure they went through the countdown and did not have a failure of the valve, or they would not have fired. I am sure of that.

Mr. BROOKS. Mr. Feldman.

Mr. FELDMAN. I want to make an observation. You pointed out just now that you are finding less and less difficulty as you fire these various missiles.

In other words, you are in this development stage and what you are actually doing is getting the bugs out of the system. Would you summarize it that way?

General SCHRIEVER. This is certainly one of the most important aspects of a development program.

Mr. FELDMAN. That is why you are doing the firings, to get the bugs out of the system?

General SCHRIEVER. That is right.

Mr. FELDMAN. And in that way to perfect the missile ultimately?

General SCHRIEVER. That is right.

Mr. FELDMAN. After you do that, then you will put them into production, into mass production?

General SCHRIEVER. That is right.

Mr. FELDMAN. At least, that is contemplated?

General SCHRIEVER. That is right.

Mr. BROOKS. And you are making substantial progress in that direction?

General SCHRIEVER. We have made substantial progress in our ability to say we are going to fire a missile on a particular day and have it go. Actually, we carry out what we call a static firing on a missile at Patrick prior to the launch. Sometimes we run into problems on the static firing which will then delay the actual launch. But once we have gone through the static firing, our prediction of the day and the hour at which we are going to launch is usually quite good.

Mr. BROOKS. Are there any further questions? If not, the committee will adjourn until 2:30 this afternoon.

(Whereupon, at 12:55 p. m., the committee recessed to reconvene at 2:30 p. m., the same day.)

AFTERNOON SESSION

The CHAIRMAN. The committee will come to order.

The next witness, and we are very happy to have him before us, is Maj. Gen. J. P. Daley, Director of Special Weapons in the Office of Chief of Research and Development of the United States Army.

We are glad to have you with us, General. You may proceed.

STATEMENT OF MAJ. GEN. J. P. DALEY,[19] DIRECTOR, SPECIAL WEAPONS, OFFICE OF CHIEF OF RESEARCH AND DEVELOPMENT, UNITED STATES ARMY; ACCOMPANIED BY LT. COL. ROLAND V. TIEDE, CHIEF, BALLISTIC MISSILES BRANCH, OCRD UNITED STATES ARMY

General DALEY. Mr. Chairman, before making my formal statement, I would like to introduce Lieutenant Colonel Tiede, from the Office of the Chief of Research and Development, who is accompanying me.

---

[19] Daley, John Phillips, army officer; b. Washington Barracks, D. C., July 17, 1910; s. Edmund Leo (U. S. Army), and Beatrix Otelie (Koehler) D.; student George Washington U., 1926–27; B. S., U. S Mil. Acad, 1931; student F. A. Sch., 1934–35, Command and Gen. Staff Sch., 1947, Nat. War Coll, 1947–48, Army War Coll., 1950–51; m. Katherine Hadley White, Aug. 6, 1932; children—Katherine Anne (*Mrs. Arthur G. Trudeau, Jr.*), John Michael (U. S. Army), Commd. 2d lt. U. S. Army, 1931, advanced through grades to maj. gen, 1952; instr. physics U. S. Mil. Acad., 1937–42; instr. gunnery and survey F. A. Army, 1955——. Mil. adviser Geneva Conf., 1954. Decorated Legion of Merit with clusters. Home: 1830 N. Patrick Henry Dr., Arlington 5, Va. Office: Dept. of Army, OCRD, Pentagon, Washington 25.

I am, as you said, Maj. Gen. John P. Daley, the Director of Special Weapons, Office of Chief of Research and Development of the Department of the Army. Within Research and Development, I have the staff responsibility for Army missile and space program. As a background for my appearance here before this committee I reviewed the tasks which face the committee. Excerpted briefly from your chairman's opening remarks—they are, and I quote, "to conduct a thorough and complete study and investigation with respect to all aspects and problems relating to the exploration of outer space," and further, "to enact effective legislation to meet this problem."

This is a momentous task. I am sure you gentlemen realize completely that the work of this committee will be reflected in the history books of coming generations. The exploration of space is just beginning. It will continue for centuries. The point I wish to make is that we should not seek a 1-year solution or a 2-year solution. We must seek a firm foundation for what I believe will be a continuing and an increasing program for the exploration of space.

I have asked myself what can I contribute to the work of this committee and it is in that frame of reference that I make these subsequent remarks. I intend to speak briefly on the military significance of space to the Army; turn briefly to the Army's contribution to present and near future space programs; and close with a few remarks with respect to the proposed National Aeronautics and Space Agency.

First, then, the military significance of space to the Army. Why is the Army interested? From the military point of view, there do not appear to be any applications of satellites and space vehicles that are unique to the Army, to the Navy, or to the Air Force.

Instead, such applications appear to be applicable to all three services. The immediate possible applications for satellites include reconnaissance and surveillance, both visual and electronic; communications of all kinds; meteorology; mapping and geodesy, to include navigation; radar targets for use in development and training in anti-intercontinental ballistic missiles systems and as space laboratories for conducting military research. All of these are national military requirements. Each of the services has resources to contribute to the achievement of these objectives.

The Army strongly supports a national integrated space program which makes use of national assets, military or civilian, to achieve national objectives, military or civilian.

The Army's interest in space has already resulted in a demonstrated capability to contribute to a national space program. The contributions of the Army to the satellite program are well known to you. Beyond these, as has been announced by the Secretary of Defense, the Army Ballistic Missile Agency has been directed by the Advanced Research Projects Agency to launch 2, and possibly 3, earth satellites and 2 lunar probes.

These latter will attempt to place instrumented payloads in the vicinity of the moon. Beyond this short-range program, the Army can make significant contributions to a long-range program for the conquest of space. The establishment of United States supremacy in space can be achieved only by carrying out a long-range national integrated program which assigns responsibility for a complete phase

of the program to competent teams such as the Army Ballistic Missile Agency and the Jet Propulsion Laboratory.

It is expected that such an assignment will be made by the Advanced Research Projects Agency, which, of course, has the task of preparing an integrated Department of Defense program.

The establishment of a National Aeronautics and Space Agency, based on the National Advisory Committee for Aeronautics, is a desirable move since it creates a national agency to deal with a national program and since it gives this new national Agency an existing framework on which to build.

On the other hand, it must be recognized that this new Agency must lean heavily on the Department of Defense for some years to come in order to carry out satellite and space experiments.

We can move into space in the immediate future only by using existing hardware or hardware that is well along in development.

Almost all of that hardware is military hardware.

I foresee no big problems of establishing effective cooperation between the National Aeronautics and Space Agency and the Department of Defense, particularly since the Department of Defense responsibility is centered in the Advanced Research Projects Agency.

In conclusion, gentlemen, the Army supports a national, not a service, space program; the Army can and wants to contribute its proven resources to such a national program; lastly, the Army welcomes creation of an agency which will insure that our national program meets civilian as well as military requirements.

Mr. Chairman, that completes my opening statement.

The CHAIMAN. Mr. O'Brien?

Mr. O'BRIEN. I have no questions at this time, Mr. Chairman.

The CHAIRMAN. Mr. Natcher?

Mr. NATCHER. General, according to the provisions of the bill that we have before us at this time, this new Agency would be a civilian-controlled agency. Have you had a chance to examine the bill?

General DALEY. I have examined the bill, I think fairly carefully, sir.

Mr. NATCHER. How do you feel about the Agency being a civilian-controlled agency?

General DALEY. I believe that it should be a civilian-controlled agency, because the terms of reference for this Agency extend not in particular to military space programs, but provide particularly for the Nation's move into space.

While many of the things that have been mentioned to this group I know have had military implications, certainly there are vast civilian implications in this move into space, the most obvious one, of course—and Dr. York is a far better witness on this subject than I am—is the advantage from a purely scientific standpoint.

But beyond this, you are looking generations ahead and man's ability to move out into space must mean a great many more things than purely military. So I say I think it should be a civilian agency.

Mr. NATCHER. General, another provision of the bill provides that the Board shall consist of not exceeding 17 members. How do you feel about that particular number? Do you feel that is too many, not enough, or just how do you feel, General?

General DALEY. I examined that wording rather carefully and I believe I have looked into the history. I believe it actually comes, or it seems to me that it derives, from the National Advisory Committee on Aeronautics. That is probably the reason for the 17. The bill says not to exceed 17 members. As a general philosophy, and I am not a legislator, in giving a man a mission to do, I believe you should set the boundaries but not the details, and when it says not to exceed 17, I assume that this is a reasonable number, and that if 17 is too many, it will be whittled away over the years to come.

I have no strong feeling that this is too many or too few.

Mr. NATCHER. Another provision is to the effect that 8, or not to exceed 9, will be from the different agencies of the Government, with 1 to be designated by the Secretary of Defense.

The CHAIRMAN. At least one.

Mr. NATCHER. At least one.

How do you feel about that particular provision, General?

General DALEY. Having put myself in my own philosophy, practically in the hole, I believe that at least one should be from the Department of Defense; in other words, I believe that there should be some representation from the military departments.

I can well visualize that more than one might well be put on this Board. But whether or not it is a wise thing to write into legislation, I don't know. As a matter of fact, we find, going back to the National Advisory Committee on Aeronautics, that they spelled it out very carefully in that, the representation from the Department of Defense.

It did not foresee the creation of the Air Force and the separation of the Air Force from the Army, and the fact that the Army members went with that left the Army without representation. Sometimes spelling these things out can be worse than not spelling them out.

Mr. NATCHER. The Director of this Agency, under the bill, is to be named by the President and confirmed by the Senate. What qualifications, in your opinion, General, should the Director of this particular Agency have? Should he be a scientist? Should he be a man with experience in private enterprise, a fine administrator?

Just what type of qualification should this director, in your opinion, have?

General DALEY. I believe first of all, and this may be a narrow viewpoint, this man must have great executive ability, or great administrative ability. You are giving him a task to run an organization and he has to be able to run an organization.

Beyond this, if not a scientist, certainly a man who has appreciation for scientists and a man who has some background to give him that appreciation.

I say if not, possibly a scientist. I know scientists who are fine administrators, and I know scientists who are not fine administrators.

I would say these are two of the key things. The third one is two moral characteristics, perhaps: A man of vision, whatever this connotes to you, a man who is not tied to what he sees right in front of him, but who can look beyond.

And certainly a man with some enthusiasm, some ability to draw people to him, some ability to tell the people of the United States what is being done and why it is being done, and to lead us. These are the characteristics I would look for.

Mr. NATCHER. General, I want to thank you for the fine statement you have made to our committee.

Thank you, Mr. Chairman.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. General Daley, in setting up a priority, if you will permit me to put it this way, of the needs that exist right now for the most expeditious action in this program, can you put a priority on a list of that kind?

In other words, what, today, do you consider to be the greatest need in order to move ahead with the program that we are contemplating?

Is it the type of agency that we are proposing to set up here, or is it something else? I realize this is a rather broad question.

General DALEY. I am trying to really consider it so I don't give you a hasty answer. I would say that in looking at the long-range viewpoint, the most important thing is to settle on, No. 1, an organization. This one will do it on the national scale. The Advanced Research Projects Agency does it within the Department of Defense. To settle on an organization or individuals who can be held responsible for where you go, I think, is a primary requisite. Having settled on those organizations, then I think it is the integration of a national program in which you must get the advice of these agencies, of these individuals who are responsible, to set long-range goals and work toward those goals.

I have a fear that, in the middle of October, we get wildly excited because there is a sputnik in the sky. It is not that we shouldn't, but we go up to a peak of excitement and we drop down. We need to set a goal that we are willing to work for, which the scientists agree is a good one, which the Department of Defense agree is a good one, something that you gentlemen, as representatives of the people, believe you can support, not just this year, but next year and the next year. This, to me, is a second prerequisite.

Mr. SISK. In other words, the setting up of a centralized authority which will have control and direction of a national, overall program.

General DALEY. These are the things that I think will help you. This will not solve the problem of where you are in July, but it may solve the problem of where you are in July of 1963.

Mr. SISK. What are your present connections or relations with NACA?

General DALEY. My direct relations? I have none. The Army does have representation on some of the boards or committees of the NACA. The Army does not have representation at the top level in the NACA, although I believe that there is a bill that would give the Army such representation.

Mr. SISK. Why have you not had representation on the NACA?

General DALEY. This, I think, is merely historical. When the NACA was established, back in 1915, that provided for representatives from the War Department then, I suppose, and the Department of the Navy. When the Air Force was set up, after World War II, the Army representatives, quite naturally, went with the Air Force. This left the Army, itself, without representatives. Since Army aviation has grown considerably since World War II, there has been, I believe, a bill presented to add Army members to it.

Mr. SISK. So, at the present time, the Army, as such, is not represented in the making of policy decisions or in anywise directing the overall program?

General DALEY. Not at the top level, sir.

Mr. SISK. You mentioned, I believe, in an answer to a question from the gentleman from Kentucky, that you felt that NACA could be the vehicle around which the new Agency could be established. To what extent is NACA failing to do the job that we need to have done today? Is it lack of authority?

General DALEY. I am a poor judge of that. As a matter of fact, all that I know is that the National Advisory Committee for Aeronautics, from anything that I have heard, has a fine reputation, sir.

But it is for aeronautics, and its relations, naturally, have been chiefly with Air Force and Navy, as far as the Defense Department goes. Its dealings, and this, I think, is within the history of the growth of it, naturally, have been mostly with the air industry.

These are things that it properly should be doing under its present charter. I say I am a poor witness, but, as far as I know, it is doing a good job. This bill takes that organization and gives it an entirely new area. It adds to it the space area of research exploration, if you will. When you do that, you can't simply take the National Advisory Committee for Aeronautics and its suborganizations and say, "This is the end-all."

In my opinion, you must broaden its contracts; you must broaden its contracts militarily and broaden its contracts civilianwise. You will, undoubtedly, have a change the internal organization, add certain types of individuals to it. But it does mean that, instead of sitting here and setting up an organization and starting in that from scratch, by naming a director, getting a stenographer, and going through the ramifications, you take an organization which has, at least, worked in part of this field, and which gives you a working structure. To me, this is a great advantage. In the Army, we cadre a unit, send a few individuals, and build a unit around it. This is the same thing.

Mr. SISK. Do you anticipate, then, that ARPA, as an organization in the Department of Defense, would continue, and that liaison would exist between ARPA and the new proposed organization?

General DALEY. I would be afraid to say "No" with Dr. York sitting this close to me, sir. But, actually, yes, sir. To me, there is a need for the Advanced Research Projects Agency in the Department of Defense; there are many of these things that are military, and there should be somebody that draws together the military programs and integrates these military programs.

The Advanced Research Projects Agency, so far as I am concerned, is set up to do that, and it is very important that it does that. At least for the next few years, the new National Aeronautics and Space Agency will have to depend a great deal on the Department of Defense, simply because we have the vehicles.

I think that Dr. York, Mr. Johnson, the head of ARPA, these gentlemen should pull together the defense capabilities and the defense needs, and that a natural point of contact is ARPA to NACA.

Mr. SISK. Pursuing that a little further, then, would you anticipate that there would be two contemporary organizations, or would you anticipate that this new Agency would actually be the top agency,

having certain authority over ARPA, or vice versa? I am curious to know to what extent and to what relationship the two organizations might fit in the picture, as you might anticipate it. What we may do, I have no idea yet.

General DALEY. I would believe that it would, largely, be a cooperative thing between these two agencies, although I think that, if there were a conflict between the Department of Defense, as represented by ARPA and this new National Space Agency, I am sure this would go right to the top levels of the Government. I would hope that it would be a cooperative enterprise, much like the Atomic Energy Commission deals with the Department of Defense in these matters.

The bill says that this Agency will exercise control over research, except insofar as activities peculiar to or primarily associated with weapons systems. In this field, then, there must be a play back and forth. I don't think you can say that this new Agency would be completely over all of the things that ARPA would control, directly or indirectly, or, otherwise, you are going to get a problem of at what point you take a space program and decide what is the conflict with the weapons program.

I think that ARPA must at least speak for the Department of Defense in this respect, or the Department of Defense speak for itself.

Mr. SISK. Of course, you could visualize some conflict when it comes to a determination, let us say, as to just what the military application of a given program might be. There might be differences of opinion. I can certainly see where, I think, that could be worked out.

General DALEY. I agree; there will be differences of opinion. There are differences of opinion between the Atomic Energy Commission and the Department of Defense, but 999 of them get argued out before they go above the departmental level.

Mr. SISK. I have one other question, General. In view of some comments, and some of the things you read from time to time, there has been some criticism of the fact that one of the reasons we have not made the most complete utilization of our scientific and engineering know-how in this country has been the fact that, in many cases, these scientists have been restricted. They have been kept under wraps, have not had a free rein, let us say, to dream and then to try to put their dreams into reality. Just how free do you anticipate we might be able to make these men who, actually, are going to come up with the ideas which ultimately will put us into space?

General DALEY. This is a very difficult problem. Actually, we have people that are allowed to, if you will, dream or think of the future. We have them in the Army Ballistic Missiles Agency. There is always the problem, quite frankly, of how much of your funds you put into this, and how much you put into hardware. I am sure that almost any of the scientists that are in this advanced reaching-forward area would say that we don't put enough effort in here.

This is just a matter of judgment. I am sure that, many times, the people that have to make these decisions, including myself, can be quite wrong and don't put enough effort in this field. I do not see why, though, you cannot give scientists, under these terms of reference, or within the Government, latitude to explore things. But, eventually, you come up to the point of how much money you will back that with. I don't know whether this is a very satisfactory answer or not, but probably not.

Mr. Sisk. I appreciate your thinking on it. The time comes, of course, where, if their dream is to be utilized, you have to have some hardware to back it up and do experimental work. Then, of course, is when the big money becomes involved. It becomes a matter of how much you are going to risk on a given idea. I appreciate that.

That is all, Mr. Chairman.

The Chairman. General, this bill provides for the head being a Director. What are your views for a commission form of agency?

General Daley. I would like to preface my remarks by saying that I get along fine with the Atomic Energy Commission, but perhaps that is from my military background. I like to know that one man is responsible. My reaction is that I prefer a Director rather than a group of individuals.

The Chairman. Have you any views as to whether we should go right across the board in research and development, of course having regard for the military—because no one can disregard what you people have said about the position of the military in the world of today and in the foreseeable future—right across the board with the establishment of a Department of Science with Cabinet status?

General Daley. Conceivably this, in the long future, looking years ahead, might come to pass some day. It is my opinion, personal opinion, that it should not be given Cabinet status at this time.

It is not the same nature and of the same scope as the organizations which are now represented on the Cabinet.

The Chairman. I meant going across the whole board, bringing in all research activities, including existing agencies.

General Daley. No, sir. I do not believe Cabinet status is correct in this case, because I do not believe it would benefit this country to attempt to put all of the research and development that is done in this country into a single department of the Government or controlled by a single department of the Government.

It is too interlaced with many different departments of the Government. It is not only a case of Army, Navy, Air Force. It is a case of the Atomic Energy Commission; it is a case of many of our other departments having research and development projects. Furthermore, a great deal of research and development is done within civilian industry.

I simply believe that it would be a very loose organization. I am not sure what it would represent.

The Chairman. I am not arguing with you. I have no presupposed views. But aren't we rather loose now? We have several departments and agencies handling research.

General Daley. Yes, we do, sir. I think that this is just fine. I believe it is just fine, especially as you get toward the development and the applied research. This is done to meet the particular needs or the particular purposes of that established department. I think it is the best judge of where it should put its effort.

The Chairman. What about putting that Agency in with the Atomic Energy Commission, merging them, for example? I am not saying that is my opinion.

General Daley. I understand, sir, entirely. I have considered this Agency and the Atomic Energy Commission, just thinking about the problem. I believe that you have almost the other side of the

coin, when you are talking about this Agency and the Atomic Energy Commission, the Atomic Energy Commission—and I am speaking of it and its laboratories, the whole organization—was set up when there was no centralized research in this one field, when there were no laboratories, no facilities in this one field, and for purposes of national security it gathered to itself tremendous resources from the country and developed and built these things.

So the resources in the atomic energy field grew up under that Atomic Energy Comission or its predecessor.

In this particular case, the resources of this Government are already spread across the width and breadth of the land.

We have some of them. Huntsville, Ala., ABMA, is just one.

We have a team there. Navy has teams. Air Force has teams. Industry has teams in these things. In view of the difficulty of pulling these all together under a single Agency, I think we are starting now when a thing is widespread and it would not fit in under the Atomic Energy Commission.

Furthermore, to take that specific example, the Atomic Energy Commission, I think one of the strengths of the Atomic Energy Commission is the fact that it deals in a particular field with atomic energy.

I have had my arguments with them, but I like that general system. I think it would dilute the Atomic Energy Commission if you threw on it this additional burden.

Therefore, I, as an individual, would be opposed.

The CHAIRMAN. Can't you see that some time in the future we may have to do it, applying the law of natural and probable consequences, projecting that line into the not remote future?

General DALEY. It is true that the Atomic Energy Commission and the products of the Atomic Energy Commission——

The CHAIRMAN. I am talking about all across the board now. I recognize the military necessities, so don't get involved in that. I am talking about on the civilian side. Nobody recognizes the necessity of military strength, I think, more than I do. Others do as much as I do, but nobody more. If I am going to err, I am going to err on the side of strength rather than weakness. Eliminate the military side. That is not involved in my question. Projecting your mind into the future, can't you see some time in the future where the importance of this activity, research, and development, would be such that there would have to be a Department created with Cabinet status, particularly if the world's tension subsides, and the important emphasis on the military does not exist as it does today?

General DALEY. Yes, sir, I could foresee that this could be so, that there might be a Department growing up. I certainly don't want any of my remarks to be interpreted to say that I am anything but in favor of pushing our science and our technology.

I certainly feel that if such a Cabinet Department were created, this should be a very evolutionary process, and to do it right now would be precipitous.

The CHAIRMAN. To the contrary, General, your answers have been very frank, and I appreciate them. You have met every question any one of us have asked you directly. I certainly don't misunderstand where you stand.

General DALEY. Yes, sir.

The CHAIRMAN. We have a reorganization bill, I think, floating somewhere around the atmosphere of Washington. You have heard of it, have you not?

General DALEY. I have heard rumors, yes, sir.

The CHAIRMAN. Not getting into that from this angle, but I noticed that the reorganization bill provides that there shall be a Director of Defense Research and Engineering who shall be appointed from civilian life by the President.

You are acquainted with the provisions of the bill, so I will not read it.

General DALEY. Yes, sir, I am.

The CHAIRMAN. Would the language regarding the Director of Defense Research and Engineering, assuming that language is finally enacted into law, interfere with the establishment of an Agency along the lines of a bill which I have introduced for the administration?

General DALEY. Not in my opinion, sir.

The CHAIRMAN. I am inclined to agree with you. I wanted to get your opinion on the record.

General DALEY. I feel that the bill there created a Director of Research and Engineering within the Department of Defense, that individual authority lies entirely within the Department of Defense. There would be more conflict, and this is simply an internal resolution by the Secretary of Defense, there would be more chance of conflict between the Advanced Research Projects Agency and that Director of Research and Engineering than there would be with this outside Agency.

My personal opinion is that somebody should represent the Department of Defense in dealing with the outside and that this would not interfere with that.

The CHAIRMAN. As a passing observation, I introduced bills a few years ago providing for an Assistant Secretary for Research and Development at both the Defense Department level and in all the service departments.

No staggering progress was made, but we made a little.

General DALEY. Yes, sir.

The CHAIRMAN. What is your opinion, assuming that 17-man Board survives the ordeal of this committee—personally, if it was something new, I would not be impressed by it, but I realize the historical development that you referred to, I appreciate the historical background of it, and the factors that create—assuming the Board survives, remains in the bill, and is enacted into law, what is your opinion about provisions in the bill to establish a liaison group between this new Agency and the Defense Department, where they would be at a constant working level?

General DALEY. I am not sure that I would favor putting this into a bill at this time. I actually have tried to resolve in my own mind: How would you exchange information? How would this Space Agency place requirements on the Department of Defense or the Department of Defense explain its requirements to the Space Agency?

Today, between the Department of Defense and the Atomic Energy Commission, you have—and it is part of the law—a military liaison committee, which states to the Atomic Energy Commission Department of Defense requirements, which tells the Department of Defense what the Atomic Energy Commission capabilities are.

I could visualize growing up, possibly, something you might call the civilian liaison committee to the Department of Defense, which would actually be this Space Agency creating a group of individuals who kept constant contact with the Department of Defense. You have almost the reverse.

The Atomic Energy Commission today has the facilities in the atomic-energy field, and the Department of Defense is the man who asks. Here you would have the Department of Defense, which has most of the facilities, and the Space Agency is putting the requirements on. There would, I think, grow up some such liaison group.

I would be somewhat skeptical about putting it into law before you established these organizations and find out how they work. This liaison function might well be performed purely between the Director of the Advanced Research Projects Agency and the Director of the Space Agency.

But I could visualize very well some liaison group being set up to be sure that the Space Agency knew exactly what the capabilities of the Department of Defense were, and to insure a steady, constant flow of information both ways.

The CHAIRMAN. Would it not have importance from that angle?

General DALEY. There must be a complete, thorough exchange of information, sir. I am simply saying I don't like to prejudge whether there need be this liaison committee actually set up by law or not, whether there would have to be. I am sure that if you set the 2 agencies up, and there were nothing set up in the law, there would have to be established between those 2 agencies a system of liaison that was complete and thorough.

The CHAIRMAN. I would agree with you that anybody administratively probably would do that.

On the other hand, he might not do it. I was thinking more from the angle of the defense of our country, to insure that the means existed by which the views of the Defense Department would, as a matter of law, be expressed. The thought I had would strengthen its position. You know the Atomic Energy Commission originally started with emphasis on the military side. It was 1954 that the emphasis was changed, without putting the military in a secondary position, and properly so.

As far as I am personally concerned in any bill, I want civilian control, but I don't want the military placed in a subservient position.

Yet I recognize the difficulties that sometime exist in human relations. The thought I had was that this might be a strengthening influence from the military angle, and I am very much interested in that.

General DALEY. My feeling is that the provisions in the bill, as it is written, appear to provide sufficient protection for both the military and the civilian.

The CHAIRMAN. What provisions in the bill are there that provide that, except blanket administration?

General DALEY. Well, the provision in the bill that says that the civilian agency is over all, except insofar as weapons systems peculiar to the military; the provision in the bill on this National Aeronautics and Space Board that there shall be at least one member from the Department of Defense.

The CHAIRMAN. You have already said that you thought that should be increased or might be increased.

General DALEY. It might well be. I would think that there might be more than one. But the law says there will be at least one.

I simply am not sure that establishing, by law, at this time, before you have established the Agency, establishing this liaison change, is necessary.

I don't believe that the law that you pass can answer all things. This is a workable bill. This civilian liaison committee——

The CHAIRMAN. I hope it will be. It is a basis for consideration, certainly.

General DALEY. It is a basis for a workable bill, sir. It is just a question in my mind as to whether you should inject into this a specific liaison at this time or not.

The CHAIRMAN. You better get what you think is in there at the outset, because it would be much easier than trying to get it in later by amendments.

General DALEY. My personal recommendation right now is that you do not inject into this a civilian liaison or a military liaison committee. That is my personal recommendation.

The CHAIRMAN. All right, General. My inquiry was a little more than a philosophical inquiry, you understand.

General DALEY. Yes, sir.

The CHAIRMAN. Mr. Fulton.

Mr. FULTON. You do feel that there should be a liaison committee of some kind between the Department of Defense and the Space Agency, do you not?

General DALEY. I feel that there must be liaison, sir. Whether this is by a committee or by individuals is a question.

Mr. FULTON. Actually, whether they wear a uniform or not is not too important to you, is it?

General DALEY. No, sir. Frankly, in the liaison in this particular case, if it were set up, I would be more inclined to make it a civilian one from the Space Agency to the Department of Defense than a military one the opposite direction.

Mr. FULTON. But that is simply because the Department of Defense, in the first instance, has moved much further than the newly born Space Agency, so that you are saying that as a preliminary matter, not as a final judgment?

General DALEY. This is correct, sir. I am saying that on the basis of the state of affairs as exists today.

Mr. FULTON. Next, though, if it were developed that this Space Agency on civilian matters would have the same preeminent position that the various services under the Department of Defense have today, you would then be revising your thinking, would you not?

General DALEY. I certainly would, yes, sir.

Mr. FULTON. Then, in the language of the bill, on page 2—and we will look particularly at lines 7 and 8, although we will start at the beginning of the sentence on line 4—"The Congress further declares that such activities should be directed by a civilian agency exercising control over aeronautical and space research sponsored by the United States, except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations, in

which case the agency may"—and I point out the words may "act in cooperation with or on behalf of" and I point out the words on behalf of "the Department of Defense."

May I direct your attention to the fact that there may be a limit on the activities of ARPA if that agency is restricted to such activities as may be peculiar to or primarily associated with weapons systems or military operations.

Do you think that limit is too severe in this legislative language?

Do you think there is room for basic research?

General DALEY. I consider that a reasonable interpretation of these words should include basic research, or research that is certainly the type of research that goes on in our Ballistic Missile Agency today. If the language were interpreted otherwise, so as to completely exclude the agencies handled by ARPA from the research field entirely, I think this would be a mistake. I think it would result in drying up the talents of your teams.

It is fine to have a little bit of advanced hardware going along, and some practical hardware research, but my experience leads me to believe that the best way for one of these teams is that it also must have a chance to reach out into the future. This we do have down at the Army Ballistic Missile Agency, if this prohibits that, then I think it should be modified.

Mr. FULTON. Could you, in conjunction General, with Dr. York, submit at this point in the record in your statement a form of language which would insure that basic research would remain in ARPA, and that there would be leeway so that the possible jurisdictional disputes might not become basic hurdles for the Department of Defense? Could you submit that?

General DALEY. Yes, sir.

(The document referred to follows:)

DEPARTMENT OF THE ARMY,
OFFICE OF THE SECRETARY OF THE ARMY,
Washington D. C., May 26, 1958.

HON. JOHN W. MCCORMACK,
Chairman, Select Committee on
Astronautics and Space Exploration.
House of Representatives.

DEAR MR. CHAIRMAN: In accordance with your request during the appearance of Maj. Gen. John P. Daley before the Select Committee on Astronautics and Space Exploration on April 24, 1958, the following suggested rewording of lines 4 through 10, page 2 of the proposed act (H. R. 11881) is submitted:

"The Congress further declares that such activity should be directed by a civilian agency exercising the control over aeronautical and space research sponsored by the United States, except and insofar as such activities are closely related to missions of the Department of Defense, in which case the agency is authorized to act in cooperation with, or as an agent of, the Department of Defense."

The rewording of the act suggested is submitted as a drafting service only and does not necessarily represent a policy position of the Department of Defense or the Department of the Army.

Your interest in this matter is appreciated and I hope the suggested amendment will be satisfactory for your purpose.

Sincerely,

J. H. MICHAELIS,
Major General, General Staff,
Chief of Legislative Liaison.

Mr. FULTON. Going a little further, look at line 10. It says "On behalf of the Department of Defense." Do you want the National

Space Agency operating on behalf of the Department of Defense?

General DALEY. Yes, sir, under certain circumstances, I can certainly foresee this. If this National Space Agency were engaged in a program which was primarily a civilian program, we will say, but one in which there was information which we could derive from that program, which would have military value, and a program which it would be more expensive or less efficient for us to handle within the military, I would like the right to go to this Agency and say "Will you, on behalf of the Department of Defense, do this for me?"

Mr. FULTON. Should it be specified more clearly as to the method of procedure that we should legislatively set out to accomplish that result? For example, should it say "By agreement of the space agency and the Secretary of Defense" or "by the approval and the instructions of the President?"

How should we accomplish that? If you and the good doctor will submit us language on that at this point, it would be helpful.

General DALEY. I might say at this point I will reexamine the words very closely. I had accepted this language as perfectly satisfactory. I will discuss it with Dr. York later.

The CHAIRMAN. Suppose there is a conflict on the language referred to by Congressman Fulton as to what activities may be peculiar to, or primarily associated with, weapons systems or military operations. Who would make the decision? Suppose this agency says it is not and the Defense Department says it is. I suppose you would go to the President, then, would you?

General DALEY. Yes, sir, I assume so. Actually, this does have a way of getting settled, too, some times, when you have to go up and stand up and state your case. If you have some weak points in it, you backwater.

The CHAIRMAN. And, particularly, when research and development commenced to be appreciated by the Defense Department. It wasn't so many years ago was it?

General DALEY. Yes, sir.

Mr. FULTON. Are you through, sir?

The CHAIRMAN. Yes.

Mr. FULTON. May we have your comments on the necessity and the urgency of the development of the million-pound thrust engine? Do you think it is, first, necessary, and, secondly, should we go on to an accelerated program of some size in its development?

General DALEY. In my personal opinion, yes, it is necessary.

Your capabilities in the satellite field today are definitely limited to the size of the engines that you have available. If you fail to provide for larger engines in the future, then you have reached the limit of your capability. A million-pound thrust engine appears to be technically feasible. I think it should be undertaken. I believe not on a crash program, perhaps, but with a reasonable effort, this is really something that is in the province of the Advanced Research Projects Agency, they must weigh this against their other requirements.

Mr. FULTON. Would you give us the time in which you think it could reasonably be accomplished on an accelerated program, and, likewise, an estimate of the overall cost? What agency should be primarily entrusted with the program?

General DALEY. I was asking Dr. York if there was anything classified in this. I would say that I think you would get such an engine,

a good engine, in 4 or 5 years. My own estimate of the cost of this, and this is a complete cost of fuels, burning up engines and everything else—this is a big engine that will burn tons and tons of fuels while developing—it will cost in the order of $200 million over that period.

Mr. FULTON. What agency would you entrust the operation to? The Army Ballistics Division?

General DALEY. I am a very biased and parochial witness, sir. I would simply say that I think the Director of the Advanced Research Projects Agency or his scientific advisers should tell you.

Mr. FULTON. Who should do it, Dr. York?

Dr. YORK. Well, I think it should be done by one of the big companies which is presently in the big rocket field.

Mr. FULTON. What Government agency should have such supervision is really what I am saying, of the planning, research and development?

Dr. YORK. I feel somewhat parochial, too. I think I would have the Advanced Research Projects Agency do it, my self.

Mr. FULTON. Could I ask this question? Would you at the same time carry on a third of a million pound thrust engine development, or would you also carry on a million and a half pound thrust engine development, starting just about the same time and realizing they have different termination points?

Or is that too broad a program?

General DALEY. These things must always be weighed against finances. I would say I would start to work on a third-of-a-million-pound thrust engine at the same time. There has been work done in this field in the past. It is an easier job than the bigger one, obviously.

Mr. FULTON. In what magnitude, generally, of cost would that third-of-a-million-pound thrust engine run? Also give us the timing.

General DALEY. May I furnish that for the record?

Mr. FULTON. Certainly.

(The document referred to follows:)

DEPARTMENT OF THE ARMY,
OFFICE OF THE SECRETARY OF THE ARMY,
Washington 25, D. C., May 20, 1958.

Hon JOHN W. MCCORMACK,
Chairman, Select Committee on Astronautics and Space Exploration, House of Representatives, Washington, D. C.

DEAR MR. MCCORMACK: The following information, requested of Maj. Gen. John P. Daley, during his appearance before the Select Committee on Astronautics and Space Exploration on April 24, 1958, is furnished for the record.

It is estimated that the development of a one-third-million-pound thrust rocket engine using chemical fuel would require 4 to 4½ years if carried out by an agency experienced in the field of large rocket engine development. The cost of such a development is estimated to be approximately $75 million.

The estimated total number of Government personnel engaged by the Army in ballistic missile and space matters 3½ years ago was approximately 2,500; the total contractor personnel similarly engaged at that time was 12,800.

The estimated total number of Government personnel currently engaged by the Army in ballistic missile and space matters is 6,600; the total number of contractor personnel similarly engaged is 69,000.

Sincerely yours,

J. H. MICHAELIS,
Major General, General Staff,
Chief of Legislative Liaison.

Mr. FULTON. Do you think there is any gain to be made, as suggested yesterday, by going into the production of a million-and-a-

half-pound thrust engine rather than a million pound? This would be on the basis that you get very little more expense and little more time to get the bigger one, and then you have passed the million-pound-thrust engine on the way to the million-and-a-half-pound-thrust engine?

General DALEY. I am really not a technical expert in these matters. However, our advice is that about a million is what should be tried. If you wanted a million and a half, you would probably cluster, possibly, some smaller engines.

Mr. FULTON. Would you advise current study of research and development on the ion engine, the ion propulsion for space vehicles?

General DALEY. There should be some study in this field, sir, but I consider this as much farther in the distance than anything we have been talking to, to this point.

Mr. FULTON. But you would continue that study and not stop any study that is now in progress?

General DALEY. Yes, sir.

Mr. FULTON. Do you consider light propulsion practical enough at the present time to have a basic research program in operation on it?

General DALEY. Basic research, really basic. But this is further out in the future, in my opinion.

Mr. FULTON. Do you feel that there should be a basic research program on solar energy propulsion with the sail effect as distinguished from the light propulsion?

General DALEY. This I am not familiar with, sir. I will say this, that as a general philosophy, if a thing is based on sound, physical principles, and we know principles which might have application to propulsion and in which we do not have all the scientific knowledge that we need, this is the kind of thing that I would look to the laboratories to explore, to push back the limits of our knowledge so that we can tell whether or not these things do have practical application.

Mr. FULTON. Would you start, if you were having the power of decision, on an immediate program for a space vehicle on the order of the kind proposed by the director of the projects analysis of Convair, the astronautics division of Convair, of San Diego, who was here yesterday? Would you try to put men into space for military purposes or simply as a space vehicle at the present time, by starting a program immediately to do that?

He says it can be done quickly, within a reasonable number of months, and for about a half billion dollars. By a reasonable number of months, I mean a few years.

We are leaving the time indefinite. But would you start now to try to do such a program practically?

General DALEY. I can't tie my remarks specifically to the Convair proposal, because I am not familiar with the Convair proposal. I believe that we should take the first steps in putting a man out into space, and this is not necessarily into an orbit.

Mr. FULTON. Then you believe with Von Braun that it would be of practical research and development value to put a man in a capsule that would go 150 miles in the air to see what would happen?

General DALEY. It is more than to see what would happen, sir. I have discussed this with some doctors of medicine, space people, and I think this would get us information on the problems of man living

in space. This, however, of course, must be weighed against the rest of the projects that the Advanced Research Projects Agency has. I think it is a practical proposal.

Mr. FULTON. It is a necessary, practical step to you, though in the development of further space flight, and should be tried, rather than classing it in the position of shooting a woman out of a gun.

General DALEY. I completely disagreed with that remark, sir, which I read in the papers.

Mr. FULTON. Well, the papers were not quite accurate, I believe, with regard to Dr. Dryden's position, but there was no distinction made as to what it might be.

It was a comment that he would not like to see projects developed such as shooting a woman out of a gun, but I don't believe he exactly equated Dr. von Braun's proposal to that. I say that in defense of Dr. Dryden.

General DALEY. I disagree with many people that I respect a great deal.

Mr. FULTON. Let me finish on this, and I will be through. Am I going too far?

The CHAIRMAN. The chairman has not limited any member yet.

Mr. FULTON. Thank you, Mr. Chairman.

In conclusion might I say this? Would you give your estimate of this lunar shot as to time? How soon can we, in the United States, make one when we have the Jupiter-C, the Thor, the Atlas, the Vanguard as boosters? Why don't we just take a straight shot at the moon without a lot of instrumentation and see how close we can come?

General DALEY. You must actually modify hardware to do this. Even something that you can say is practical with devices that you have, still takes time to put together. This is why you just can't, or I can't, or Dr. von Braun can't, walk down to Cape Canaveral, put up a Jupiter-C, and shoot up at the moon. A lot of people have to do a lot of things to that vehicle. Even if it has the proper propulsion, the guidance and everything else, these things have to be worked on, and it takes months to do it.

Mr. FULTON. You and the good doctor sitting next to you have the responsibility for doing it, don't you?

General DALEY. We have the responsibility for making such a shot; yes, sir.

Mr. FULTON. What kind of a program are you putting on to do it?

Is it simply an accelerated program, a crash program? Are you doing it in deference to the fact that there may be a race with Russia to see who gets to the moon first? Is that in your thinking? Or are you just going about it on a scientific development pattern that has other factors that you don't want to interrupt, other programs now existing?

Have you given it the clear green light, like developing synthetic rubber during World War II?

Is this a program which is taken up in relation to other research and development programs you might be working on?

General DALEY. We stated our best capabilities to do this and certain other things to the Advanced Research Projects Agency. Certain of these projects were funded, based on our capabilities. I do not believe that we could materially shorten the time scale of the various things that we are doing.

Mr. Fulton. It has a first priority with you, though, so that no other project is holding it back?

General Daley. There has been no conflict that has held it back. We would face quite a decision, for example, if there were a direct conflict with the Jupiter, which is a national program. We would have to go above the Department of the Army level before we resolved such a conflict. To date we have been able to avoid it.

Mr. Fulton. How long do you think it will be before you can put a man in some kind of an instrument that would shoot him to Europe? How long will it take? That is, in view of the shot today of about 5,500 miles that took—what? 30 minutes, was it?

General Daley. I imagine that shot took on the order of 30 minutes.

This is what it would take a man to travel there. There are a lot of other things in between, of course. The man who went would like to be in good shape when he arrived. This is quite a problem. This is quite speculative on my part. I would bow to Dr. York or almost anybody on how long this would take.

Mr. Fulton. What is your judgment at this time?

General Daley. If you set out to do it, in this specific thing, perhaps 5 years or maybe 10 years.

Mr. Fulton. Thank you. That is all.

The Chairman. Mr. McDonough.

Mr. McDonough. General Dailey, I appreciate your appearance here and the information you have given the committee. In the fourth paragraph of your statement, you outlined certain things that you thought were essential, for satellite exploration, reconnaissance, surveillance, meteorology, and navigation.

You don't say anything about weather. Everyone else coming before us has stated that weather is one of the most important items.

General Daley. I included weather, sir, under the broad terminology of meteorology, of studying the whole effects within the atmosphere, the wind currents and everything else. I included weather under the heading of meteorology.

Mr. McDonough. We had a witness yesterday or the day before yesterday, Dr. Ramo, who estimated that weather was the most vital thing, especially to the military, for the use of a satellite orbiting the earth. Do you agree with that?

General Daley. No, sir, I do not. I believe that weather is a very important contribution. I think possibly from the civilian standpoint weather might be as important to the civilian, or more important to the civilian, than to the military. I think this is one that is mutually supporting.

But from a military standpoint, I think possibly reconnaissance and surveillance would rank higher in my own mind.

Mr. Fulton. A California Congressman should not be too worried about the weather, should he, General?

Mr. McDonough. Not in California. I am talking about around the world.

Do you think that the average citizen realizes the importance of space exploration?

General Daley. Sir, I would say that this committee is a great deal better judge of the average citizen than I am, but it is my opinion that the launching of the satellites, the very fact that these committee hear-

ings have been going on, and have been on the front page of most of the newspapers that I have seen, you are educating the people so that they realize the importance of it.

Mr. McDONOUGH. I think it is fascinating, and has challenged the imagination of the average citizen. But whether they realize the significance of it from a military and economic point of view is the thing. I wondered if you had any opinion on it especially. You have been in it for some time.

General DALEY. I have a feeling that the average citizen is becoming more and more aware of it. I would say that certainly it is a long educational process.

Mr. McDONOUGH. Insofar as you are concerned, do you think we are at the present time progressing fast enough in the development of missiles, satellites, and rocket development?

General DALEY. Sir, I think if I were completely satisfied, they ought to throw me out. No, I am not satisfied. I think that I always ask for more money than I get, and this is a natural consequence of democratic government. I understand this.

But, obviously, I woud like to push things faster if I knew how. I am not always satisfied with my own performance or the officers that work with me, though generally I am.

It is just a case of push, push, push.

Mr. McDONOUGH. Are there practical things that we could be doing now, if we had more money to do them with, that would augment, supplement, and expand our military potential in missiles and rockets?

General DALEY. In big missiles, I think that the amount of money that has been made available by Congress, the amount of effort that is represented by industry and by Government agencies, representatives, in the big missile field, and I include our Jupiter, constitutes practically a maximum effort at this time, or at least a maximum useful effort.

I question whether more could be spent wisely.

Mr. McDONOUGH. That is the point I wanted to make.

General DALEY. In the satellite field it is a question of judgment on how much you could spend. You could spend more. Whether this is wise or not, I don't know. This is up to the director of the Advanced Research Projects Agency.

Mr. McDONOUGH. Does your office have anything to do with the present construction of a spaceship, manned or unmanned spaceship, or am I asking for classified information?

General DALEY. Sir, that is what I was trying to decide. We are authorized, certainly, to investigate this. This is as much as I care to say on the subject.

Mr. McDONOUGH. The Pied Piper is not under your jurisdiction, is it?

General DALEY. No, sir; it is not.

Mr. McDONOUGH. That is a known spaceship being constructed?

General DALEY. It is a spaceship, but I don't believe a manned one.

Mr. McDONOUGH. I notice you said something about the Atomic Energy Commission operating in one field and the Space Agency in another.

Don't you think there is a correlation of the two that will require a direct connection, because certainly we are to use nuclear power

for propulsion and there should be a closer relationship than what you indicate.

General DALEY. I feel sure that we must explore, develop, find out how to use nuclear propulsion in these vehicles.

I am sure this, compared to a chemical rocket, is a longer range program. I am sure that the Atomic Energy Commission and its laboratories must contribute to this.

I do not believe that this necessarily means that the two organizations have to be one.

Mr. MCDONOUGH. I agree with that, not one, but there should be a very close working relationship.

General DALEY. There must be close working relationships, yes, sir.

Mr. MCDONOUGH. In that connection, the bill provides for at least one representative from the Defense Department. Do you think there ought to be more than one from the Defense Department and one especially for nuclear power, for propulsion and for ballistic purposes?

General DALEY. If there were more than one from the Department of Defense, it would be my opinion that it would be probably preferable to appoint them on the service basis as is now done in NACA where you have an Air Force, Navy, and Army representative.

As far as the representation in the atomic energy field, the bill certainly permits it. I would suppose that if it were necessary that the representative here would probably come from the Atomic Energy Commission or its laboratories.

Mr. MCDONOUGH. That is all, Mr. Chairman. Thank you very much.

The CHAIRMAN. Mr. Keating.

Mr. KEATING. General, you consider, do you not, that it is not fanciful, but it is practical, for us to talk about future transportation of man and material in a capsule form by shooting him up in the air in a rocket and landing him some distance away?

General DALEY. It is fanciful to the extent of talking about it in the immediate future. I can well foresee that as you learn more about moving through space that this is a possible way of transporting men and material, a way which should be investigated.

If it were done in terms of today's hardware, the economics today would ruin you. On the same basis, I think if anyone talked about transporting men to Korea by aircraft from California or from Washington back in 1915 or something, the cost also would have been staggering, but it came about.

I simply think this is out in the future, not something for tomorrow.

Mr. KEATING. But you have drawn a very reasonable analogy in my thinking between the two. We are in the early developmental stage in this entire area and we have to look to the future in our thinking.

General, you discussed with one of the members a department of science and we are inclined to think that was undesirable at the moment. Let us put that aside for the moment.

Do you consider that the director of this agency should have a voice in the formulation of national policy at the very highest level, similar, let us say, to the Chairman of the Atomic Energy Commission who sits, at times, with the Cabinet and with the National Security Council?

General DALEY. Within his field, the director should have access to the President, in my opinion. This, however, I do not believe necessarily means sitting in on all National Security Council meetings or things of that nature.

However, I think he should have access to the President and he should be certainly completely informed on everything that goes on at the top levels of the Government so that he can tell when his things are affected and when he can affect things that are going on.

Mr. KEATING. Of course, he should have a voice in anything that affects space.

General DALEY. That is correct, yes, sir.

Mr. KEATING. There is no reason why we could not have a liaison arrangement with the military or any other department of the government without putting it in legislation?

General DALEY. That is a correct statement; yes, sir.

Mr. KEATING. Do I understand it to be your feeling that that is a better way to handle it rather than lay down the lines of liaison in legislation?

General DALEY. That was my statement. In my opinion, I would not put it in legislation at this time.

Mr. KEATING. It leaves it a more flexible arrangement, if you can handle it through administrative channels?

General DALEY. I am not sure whether it is a more flexible arrangement but it does not prejudge what the setup will be.

Mr. KEATING. Do you look upon astronautics and aeronautics as two entirely different fields?

General DALEY. Not entirely different, but considerably different, sir.

Mr. KEATING. Do you look upon outer space as different from the atmosphere immediately above the earth in kind or degree?

General DALEY. I recognize that this is a limit, that you cannot just draw line through it, but the kinds of vehicles that will move in what you call outer space are not the kinds of vehicles that move from Washington National Airport now out to the other cities in our land.

These are air-supported vehicles. The characteristic of space as it exists today or what we call space is such that the air is rare enough so that it won't support the vehicles we know today.

Mr. KEATING. General Schriever testified this morning that about 3½ years ago, and these were rough figures, there were about 5,000 people engaged in all employment related to what he calls space matters.

Today there are 80,000 roughly and he forecast an increase in that figure.

Could you give us any comparable figures for Army development? The Army, I guess, perhaps has done more of this development—what is the phrase you use, in-house?

General DALEY. In-house is the phrase that has been used.

Mr. KEATING. More than the Air Force, is that right?

General DALEY. Yes, sir. There is no question about this because we have used our Army Ballistic Missile Agency, the team headed by Dr. von Braun who spoke to this Committee, we have used that team as a nucleus around which much of our work has been done.

Mr. KEATING. It is only rather recently that the Army has contracted for the development?

General DALEY. We do a considerable amount of the work by contract. It is not actually performed, much of it, at Huntsville, Ala., by the Army Ballistic Missile Agency, but we have used as the guiding engineering talent, the talent of the Von Braun team and they have done some of the work at the Army Ballistic Missile Agency, a large part of it has been let out to contractors like Chrysler, Ford Instrument Co. We do a lot of our satellite work at the laboratory of the California Institute of Technology.

There is a difference, though, because the Air Force generally even puts the systems development out and therefore puts more in this field than we do.

Mr. KEATING. Would you be able to give us any comparable Army figures?

General DALEY. I can furnish them for the record, sir.

Mr. KEATING. Suppose you do that.

General DALEY Yes, sir.

Mr. KEATING. Thank you very much.

(The information requested is on file with the committee.)

Mr. O'BRIEN (presiding). Mr. Ford.

Mr. FORD. I have no questions. I have been fortunate enough to have heard General Daley a number of times on our other committee, and I think, for the purposes of this committee, most of the questions have been asked.

Thank you very much, Mr. Chairman.

Mr. O'BRIEN. If I may say, I did not ask any questions at the beginning and I have only one brief one now which may or may not be pertinent.

We have had considerable testimony here as to whether we are utilizing now as much of the scientific capability as we have in this country.

The thought occurs to me, is the military utilizing as efficiently as it should the talents of the young engineers or scientists who may come to the military through the draft or enlistment?

General DALEY. Sir, I would say in the first place that as efficiently as we should would be 100 percent efficient, and I am sure we don't do it, but I am sure that we are trying and we do have procedures that provide for highly qualified scientifically trained individuals to be put into jobs where we can make use of their scientific talent.

You will find considerable numbers of these individuals working at the Army Ballistic Missile Agency. You will find them working at White Sands Proving Ground. You will find them working at Fort Bliss in the missiles schools there.

These I know from personal experience. I have met them, I have seen them, and I have heard them make briefings. We are aware of the fact that there is still talent and we want to use it.

The only way to use it would be to use it perfectly and I am sure we don't.

Mr. O'BRIEN. I did not intend that even indirectly as a criticism. I wanted to bring out a point that where we do occasionally have a snafu like a highly trained young man peeling potatoes, that is the exception to the rule.

General DALEY. It is, sir.

Mr. FELDMAN. General, I would ask you again to address yourself to the language in the bill which reads:

Except insofar as such activities may be peculiarly associated with weapon systems or military operation.

The United States Weather Bureau, the Army Signal Corps, the Air Weather Service, the Naval Bureau of Aeronautics are all interested in weather.

Where would you put meteorological satellites?

General DALEY. I believe that I would probably put it under this National Space Agency and I would probably execute the work through the Advanced Research Projects Agency and through the existing military departments.

Mr. FELDMAN. Somebody might disagree with you on that conclusion, is that not so?

General DALEY. I am sure they might. I thought that was a very wise question you asked.

Mr. FELDMAN. How would you resolve it except through some liaison?

General DALEY. The primary way to resolve something like this would be, if this Agency were set up, the director of this Agency and Mr. Johnson of the Advanced Research Projects Agency, would have to sit down together and state their case.

Initially I think what would happen is that somebody at a lower level in each agency would sit down and the reason I gave the answer I did was that I thought it does have wide civilian application, but the resource to do this quickly lies within the Defense Department.

Mr. FELDMAN. You will agree that there might be a number of other instances of this kind?

General DALEY. That is right.

Mr. FELDMAN. And the director, who is on top of an agency of that kind, should be relieved of as many of those functions as he can be. At least, he should be so briefed on them that he does not have to spend so much time with them that he is unable to do his job in an orderly and efficient way. Is that not so?

General DALEY. That is correct.

Mr. FELDMAN. Now, the proposed Space Agency creates an Aeronautics and Space Board that is to meet no less than four times a year.

The Chairman of that Board is not to be from any branch of the government and is to be appointed by the President.

We are told that the reason he is not to be a Government representative or a military representative is because there might be a conflict of interest involved.

Are you acquainted with the membership of the NACA Board as it is presently constituted?

General DALEY. No, sir, not personally.

Mr. FELDMAN. There are some members on the Board who are employed by companies or connected with companies that are engaged in the making of hardware.

The new proposal gives the new Agency the authority to build hardware. Might there not be the same conflict of interest which Dr. Dryden told us about the other day, when he testified in that situation

as there would be in the case of a Government representative serving as a chairman?

General DALEY. I am not a witness as to the conflict of interest or whether there is one in the NACA. I accept your statement.

Certainly there is a chance for a conflict of interest. There is, to me, a somewhat different connotation here, though, and that is that the object here is to make a civilian space agency and it seems to me that one of the first things I would want in a civilian space agency is a civilian director.

Mr. FELDMAN. We are not talking about the director now. We are addressing ourselves particularly to the Space Board.

General DALEY. This says that the Chairman of the Space Board shall not be military.

Mr. FELDMAN. That is right.

General DALEY. I find nothing to argue with this. Frankly, I think this is a civilian agency. The military representation is possible, but making the chairman a civilian seems perfectly appropriate to me.

Mr. FELDMAN. I was not addressing myself to the fact that he should not be a civilian. I was addressing myself to the fact that Dr. Dryden stated that the reason why he should not be a military man and the reason why he should not be otherwise connected with the Government is because there would be this conflict of interest.

In other words, if he happened to be from the Air Force he might favor the Air Force. By the same token, using that as a premise, would not a civilian who was appointed Chairman of the Commission, who was connected with a company or had an interest in a company or had stock in a company that was making hardware that might be used by this Agency, also be subjected to the same criticism, namely, the conflict-of-interest charge?

General DALEY. Sir, obviously he could be charged with a conflict of interest. I arrived at my reason for having a civilian chairman not for the same reason that Dr. Dryden did. I think for a civilian agency it is good to have a civilian in charge.

Mr. KEATING. I think perhaps the counsel has not gotten through to you as to the provisions of this bill which have nothing to do with military or civilian. The bill says that not more than 8 of the 17 shall be connected with any department of the Government, and then, presumably, there would be 8 from the Government and 9 from outside. Dr. Dryden's point of view was that the bill says that the Chairman shall be chosen from outside of the Government. Dr. Dryden made the point that the Chairman might just as well be from within the Government, because there would be the same conflict of interest outside the Government as in.

The reason given for selecting the Chairman from the nine outside of the Government was that, if they were in the Government, they would have a conflict of interest, not necessarily military. But, if they chose one from the military, he might favor the military, or the Atomic Energy Commission, or the Weather Bureau. They might have a slant in that way.

I guess what counsel wanted from you was whether you felt that the same conflict of interest might apply outside the Government as well as inside.

Mr. FELDMAN. I was thinking of the present constitution of the NACA Board and the possibility that, since it is the block upon which the new Agency is to be built, it might be lifted over, in toto, and there might be some criticism along the lines I discussed.

For that reason, I am trying to prevent that embarrassment from occurring.

Mr. KEATING. I do not suppose there would be any embarrassment in moving the Board over from the NACA. If that was anybody's thinking, it certainly was not mine.

Mr. FELDMAN. That is partly what I had in mind. General, I want to ask one more question. This proposed Space Board would have no power except to recommend. In other words, the Director does not have to accept any recommendations; he can do as he pleases. So, the function of the Board is purely advisory. Now, I also thought that the word "advisory" meant just what it said, give advice, and that you could not use that as a liaison agency.

The word "liaison," to me, means coordination. It means letting the right hand know what the left hand is doing. If you are of the view that, because you had representation on this Space Board, therefore, you had liaison with the new Agency, I would ask you to reconsider your answer. Please do so in the light of the fact that No. 1, the Space Board would meet no less than 4 times a year, probably 8 or 10 times a year, and, secondly, the fact that I believe liaison requires being in constant touch with what is going on in the agencies involved.

General DALEY. I certainly agree with your last remarks. I would not say that this meets the requirements of liaison. It helps; it would mean that you would be there and have a representative present any time they initiated a major policy or made a major program change, because they will be consulted prior to this time, the Board will. However, you must have a day-to-day contact.

All I am saying is that I do not believe it is necessary to spell out out in this law, nor do I think it is desirable to spell out in this law, how that liaison will be created at this time.

Mr. FELDMAN. What harm will there be in doing it at this time?

General DALEY. I certainly believe in laws, but I believe when you lay down too many administrative details in laws they come back to haunt you. This is the only thing that worries me.

Mr. FELDMAN. If you have a body with the experience of the AEC, which has proven that you do not have anything to haunt you, you want to borrow from that body of experience, don't you?

General DALEY. That is correct, and I am a member of the Military Liaison Committee. My personal opinion is that I would not put that into this law at this time. It is quite a possibility you might want to, a year or two from now. But I would say set up the agencies and find out.

Mr. FELDMAN. If you have found out, on the basis of experience, that it is a good thing, wouldn't you want it in the law itself? It is not a basic provision.

Mr. KEATING. You would see no objection to having a sentence that there shall be liaison?

General DALEY. No, sir.

Mr. KEATING. All you object to is setting up the details as to how the liaison is to be accomplished; is that right?

General DALEY. That is right.

Mr. FELDMAN. I will say that you are the only military man who has objected to it.

General DALEY. It is not the first time I have been alone, sir.

Mr. KEATING. That is not my understanding of the testimony. I think, if you refer to the question put to the other members of the military, I think the question that was put to them was, "Would you favor setting up liaison between the military and the civilian?" Probably, they meant just what the general says, that to have a sentence in there saying there shall be liaison is fine. But I did not understand that the others had said that we should outline the details of just how that was to be effectuated. If that was so, it escaped me.

The CHAIRMAN. I asked questions of them, and my recollection is pretty much the same as Mr. Feldman's, except that I agree we did not discuss writing out the details. That was not gone into. You would not have to write out the details. That depends on the sense of responsibility that exists between understanding men. You can write all the details and, if the men are stubborn, you will not get anywhere. They, first, have to have an understanding and appreciation of their trust and the overall national interest. I assume that will exist.

Once in a while you meet a situation where it does not. So, I do not think there is much difference all around. As a matter of fact, it was thought by some of us that the liaison group, based on the experience of the AEC, would have a strengthening influence, particularly in this trying period, from the angle of the military, which would inure to the benefit of our country. It would enable them constantly to get information, to keep in contact, and to have their views represented over and above this 17-man board, whatever the representation might be on that.

Mr. KEATING. I am not familiar with whether the AEC law sets up the method by which liaison shall be effected or whether it just deals with the subject in broad terms.

Mr. FELDMAN. Relatively broad terms.

General DALEY. The Military Liaison Committee was established by the law establishing the Atomic Energy Commission.

Mr. KEATING. Your impression is that we are not ready for that step yet with regard to a space agency?

General DALEY. That is correct.

The CHAIRMAN. Why not?

General DALEY. Sir, this really has very little to do with the establishment of this particular Board. It is my feeling that you are setting up a new agency. It is dealing with another relatively new agency representing the Department of Defense. Set these agencies up. Let them establish liaison. They will establish liaison. They have to establish liaison.

Mr. FELDMAN. On a hit-or-miss basis?

General DALEY. On this basis.

Mr. FELDMAN. On a hit-or-miss basis, it could be, if it was not in the law.

General DALEY. It could be, if you get an inefficient director and an inefficient director in the DOD.

25973—58——46

Mr. FELDMAN. Precisely. When you draft something, an order or anything else, whether legislation or whatever the document is, you want to make that as specific as you can so that there can be no misunderstanding, if you can avoid that misunderstanding at the outset.

The CHAIRMAN. You are giving one man a lot of power, are you not?

General DALEY. Yes, sir.

The CHAIRMAN. Particularly in the Director, like in Defense, because over him there is the Secretary of Defense. In a democracy, you realize the fact that this man is going to have a tremendous amount of power?

General DALEY. That is correct, sir. Any time that you give a man great responsibility you must give him equal power. I believe that he, within our democracy, is controlled by the fact that he is subordinate to the President. He is controlled by the fact that he must come to the Congress and explain what his programs are.

He must defend his money to the Congress, he must serve the executive branch of the Government, he must serve the legislative branch of the Government, and furthermore, when you establish the laws, he must serve the judiciary.

So I believe you are protected.

The CHAIRMAN. That is very nice and very correct, but there are an awful lot of things that go in there. Those of us who have been in Congress more than 30 days know just what the human difficulty is.

General DALEY. I think the most expert witnesses are sitting around here, sir, and I should probably be asking the questions.

The CHAIRMAN. I would not agree to that, but I would not deny it.

Mr. FELDMAN. I have just one more question.

Are you aware of how long it takes for an amendment or statute to go through the Congress?

General DALEY. No, sir, I am not.

Mr. FELDMAN. Well it takes a long time.

Mr. KEATING. It depends on the circumstances.

Mr. FELDMAN. I am talking about the average. You just cannot press a button and get an amendment through.

General DALEY I am sure that is true.

Mr. FELDMAN. Consequently, if you can get a good job done from the outset, from the drafting experience, from the administrative point of view, from a political science point of view, it is a good thing. You do that in your everyday work in the military, I am sure.

Mr. KEATING. I will just make the comment to counsel that the chairman of this committee has sufficient influence to get an amendment through the House of Representatives. I saw him the other day introduce a bill and 5 minutes later it was passed.

The CHAIRMAN. That is true, but before that was done, the majority leader consulted with the minority leader, the minority leader consulted with the ranking members on his side of the committee, and the majority leader consulted with the ranking members on the majority side and we cleared it through the Speaker.

Mr. KEATING. That is the way the gentleman operates.

The CHAIRMAN. I agree that there must have been some pushing force. That is all right. There has to be a motivating force.

I like to have the benefit of other views. I find that I am wrong, myself, so often. You gentlemen here have helped me inestimably on

this committee, and I have kept you working morning and afternoon with all my other work.

Other than the driving force, I probably have not contributed much. But it is a matter of consultation. I do not think there is much difference between any of us and the general.

I think in this period of the world's history, I would like have John McCormack, an American who is on the civilian side of Government, know that the viewpoint of the military will always and completely be expressed.

That is the thing I have in mind. You do not quite grasp my viewpoint, I think.

General DALEY. I think I understand your point of view, sir. Maybe I am more optimistic as to whether this would work or not, as to whether I would get an opportunity to express my viewpoint.

Mr. METCALF. I am glad that you have expressed a viewpoint, General, that is somewhat different from the other members of the military, especially as a member of the military liaison committee and the experience that that committee has working with the Atomic Energy Commission.

I respect your opinion because of your experience. You are suggesting that we make a general declaration of policy, perhaps in section 1, that there should be constant and continuous liaison, and then leave it up to the Director to set up the kind of liaison that he feels will be most efficient and then wait a while until we see how that works before we write that into legislation.

Is that your suggestion?

General DALEY. That is correct, sir. If it needs a modification, I would make it a general modification. I would not spell out as the law presently does. The Atomic Energy Act says there will be a chairman and it tells who he will be and it says there will be at least 1 representative, at least 1, although there can be 1 from the Army, Navy, and Air Force, and it spells out the duties in detail.

I think it is premature to put it in this bill. Now I can be wrong.

Mr. METCALF. I think as a member of the committee that is functioning and a very experienced individual in this whole field, your opinions are entitled to a good deal of respect. So perhaps we should say here in the enumeration of activities on page 2 of the part of the declaration on policy that there shall be constant, continuous liaison with the military over and above the liaison that will necessarily be established as a result of the creation of a member on the Board.

General DALEY. This to me might even strengthen the bill.

Mr. METCALF. Thank you, General.

Mr. O'BRIEN. General, I know there will be one more question. We have on the committee a Navy lieutenant who is trying to get promoted. He has had some difficulty in a recent examination.

He has stated his problem to all of the learned witnesses who have appeared here. Perhaps I do not state it accurately, but it spells out something like this to me.

If a man is going in six different directions at the same time, at the same speed, where is he going?

Do you have an answer to that?

General DALEY. No, sir. I am afraid I do not.

Mr. FULTON. Could I restate it?

Mr. O'BRIEN. Go ahead.

Mr. FULTON. We received this question on the Navy reserve promotion point list: "If a vehicle or missile is in a position where the thrust equals the drag and the lift equals gravity, what is that vehicle or missile doing?"

I wish you would not consult with Dr. York.

General DALEY. I would have flunked the Navy examination.

Mr. FULTON. Maybe the three of you could answer that.

Dr. YORK. It is flying steady, that is all.

Mr. FULTON. That is to say, constant, level flight?

Dr. YORK. Yes; that is what I meant, flying steady straight and true.

Mr. FULTON. Is it in a line conforming to the circumference of the earth or is it a plane that, as it comes out of a climb, reaches the stall point.

Dr. YORK. It is flying straight and steady, flat.

Mr. FULTON. A straight line or parallel with the earth's circumference?

Dr. YORK. It could be either. I don't think when the question was asked they had that kind of detail in mind.

Mr. FULTON. Would you have to say something about a constant velocity?

Dr. YORK. That is what I meant by steady; yes.

Mr. FULTON. It is not a plane that reaches the peak of its climb and goes into a stall?

Dr. YORK. No.

Mr. McDONOUGH. It is not the same as an irresistible force meeting an immovable object?

Mr. O'BRIEN. General, I know I speak for the chairman of the committee and all the members in expressing our very great gratitude to you for your testimony and your frank response to the questions, even though I think you failed on the last one.

General DALEY. Thank you, sir. I am glad to have been with you.

Mr. O'BRIEN. Now we have Dr. Herbert F. York, Chief Scientist, Advanced Research Projects Agency of the Department of Defense.

Dr. York, welcome back.

STATEMENT OF DR. HERBERT F. YORK, CHIEF SCIENTIST, ADVANCED RESEARCH PROJECTS AGENCY, DEPARTMENT OF DEFENSE

Dr. YORK. At the behest of one of your colleagues, I am supposed to be catching an airplane at 6 o'clock. I have a statement about the role of ARPA in its relationships with NASA in all of this, presuming that there is an NASA.

I could either read it or leave it for insertion in the record, whatever you prefer.

Mr. O'BRIEN. Since you have that time problem, I would suggest that you put it in the record.

Mr. SISK. Do you have extra copies, Doctor?

Dr. YORK. Yes.

Mr. FULTON. Could you summarize it orally?

Mr. SISK. How lengthy is it?

Dr. YORK. Not very.

The CHAIRMAN. I think the doctor should use a little judgment. Give us a summary, doctor, and we will put your statement in the record.

Dr. YORK. The role of ARPA vis-a-vis NASA, presuming there is an NASA, as we see it now, is that ARPA will do the programs which are primarily military in nature, and would also do supporting development and research programs related to those.

Those programs which are primarily nonmilitary or primarily civil in nature, including such things as basic science, for example, would be done by the NASA.

There is a considerable gray area in between which we have to resolve. In some cases we would suggest that there be permitted a wide variety of methods of operating such as now exists between the NACA and the service.

We suggest that there be joint programs, that there be cooperative programs, and that there be coordinated programs.

In the case of a coordinated program, for instance, an example is satellite communications relay development where there are civilian applications. There are also military applications.

The military applications may very well be quite different. Security may be involved or something like that and there might very well be two communications relay programs and these would be simply coordinated so that the research and development results of one could be used by the other.

A joint program would be one where we actually set about doing a program something like, for example, the way the X–15 is being developed between the NACA and the Air Force and the Navy, the three agencies work directly together at most all points in the program.

Another way, at least for the time being, of deciding on who should do what in these gray areas, we would suggest, would be on the basis of who is best able to carry it out at the particular time.

As far as coordination with NASA, we have what I think is a fairly good start already in working with NACA. For the space science programs; that is, those which are basic science and which presumably under almost any reasonable definition here would go to NASA, we already have a coordinating board in operation.

This Coordinating Board consists of ARPA, the NACA, the National Academy of Sciences, and the National Science Foundation.

We work out what it is that should be done in the way of space programs, space science programs, and in fact what we do in general is that ARPA brings to this Coordinating Board the information on what vehicles can be expected, what capabilities are coming along, what are the possibilities for payloads, destinations of space vehicles, and so forth, transmits this information to the other members, and then in this particular the National Academy of Sciences, just as in the case of the present IGY year, there is a committee which goes over all of the proposals in the scientific community, establishes priorities, and so forth, and then it would be our hope that the National Science Foundation or some other agency with funds for basic research would support the payloads.

This sort of thing is already in progress and I hope would continue.

The way we are operating is that we do not assume that there will be an NASA when it comes to trying to round up support for funds, facilities, people, and so forth.

ARPA goes ahead as if there were not going to be an NACA or an NASA.

On the other hand, we take into account the fact that there no doubt will be something of this sort by always making sure that anything which could be even remotely considered as a civilian program is something which the NACA people approve of and we check over all of our programs with them as we go.

This is what we are doing in order to do what I think is extremely important and that is get a space program going right now and not wait for all of these questions to be resolved.

Mr. O'BRIEN. Does that complete your summary, Doctor?

Dr. YORK. Yes, sir.

Mr. O'BRIEN. Without objection, your full statement will be made a part of the record.

(The statement is as follows:)

Mr. Chairman and members of the committee, I appreciate the opportunity to discuss with you the role that the Advanced Research Projects Agency plans to carry out in the field of space technology. I shall emphasize the type of programs and projects that ARPA will carry out.

You are aware of course that the President has stated that ARPA will conduct for the Department of Defense those programs which are primarily of a military nature, and that other programs, those of a civil or commercial nature will become the responsibility of the National Aeronautics and Space Agency, if this organization is established as he has recommended to Congress. The emphasis here is on the words "primarily military" and is the guide that we must go by in selecting, in cooperation with NASA's predecessor the NACA, those projects that fall in our respective areas of responsibility.

I am sure that you realize that this selection is not an easy one to make for any specific project or program. It has been proven many times in the experience of the Department of Defense that developments that at first appear to have no conceivable military use will often have important implications on national security. These developments, then, may form the basis for new weapons that greatly reorient the strength of our military position with respect to other countries. Certainly some of the earlier explorations into nuclear physics fall into this category, and there are many more of lesser significance.

It is also true that many developments that appeared to be only of military interest have turned out to be of great benefit to the scientific civil and commercial interests.

We are generally prone to work on the subjects or projects that we know best how to do and that we can foresee will, with a high degree of reliability, provide a system that will solve a known problem. This is the easy thing to do and will lead to minor improvements in existing systems and eventually to complete obsolescence of our military weapons and technology. Accordingly, it is vital for us in maintaining our leadership in the technological area to look as far into the future as we can and grasp at every new idea to see if it has significance in the military sense

The primary purpose of the Advanced Research Projects Agency is to take this long look ahead for the Department of Defense on an integrated three-service basis and provide a source of new weapons technology from which the weapons systems requirements of the military services can be satisfied. The areas where it is most important to apply this service of ARPA at the moment are that of space technology and in certain aspects of the antiballistic missile field. With regard to space technology the Department of Defense, even when space was unpopular, and in fact was perhaps something to hide under the table, was active in studying its potentialities and had many small projects in being, ready to be expanded into military uses when the need arose. Advantage was taken and is being taken of the existence of large guided missiles as the basis for space vehicles for military purposes. Military rocket technology made possible the swift development of the Vanguard satellite launching vehicle, the launching facilities and the tracking network in support of the International Geophysical Year. This project demonstrates that the Department of Defense can work successfully and on the best of terms with the civil and

scientific community in a cooperative venture in which the Department of Defense is providing a nonmilitary service to the Nation. We have had a similarly successful relationship with the NACA in the past and expect to continue to do so in the future.

This brings us back to the problem of deciding what is primarily military in the field of space technology and what is scientific or civil or commercial. ARPA is currently in the process of working out with the National Academy of Sciences, the National Science Foundation, and the NACA a program for civil and scientific activities in the field of space, and with the NACA a method of operation whereby the two organizations can contribute their own best capabilities to the furtherance of the country's interests in the exploration of space.

Where it is apparent at a particular time that techniques or projects or systems are primarily military they will be retained by the Defense Department. Where it is apparent that they are not primarily military, they will be transferred, in due course, to the NASA. But there are many projects or programs where it is not possible to determine which side of the line these projects will fall. In this case we would propose that these be assigned on the basis of which organization is in the best position to pursue them. There will be other cases where rather similar endeavors will need to be carried out separately but on a coordinated basis between NASA and DOD and still others where the project will be carried out under the primary cognizance of one organization but with the very active participation of the other. It is most important, and I cannot emphasize this too strongly, that promising technological ideas must be developed by one or the other Agency rather than let such a possibility lapse by reason of uncertainty as to within whose responsibility it falls.

Mr. METCALF. As I understand it, Dr. York, your proposal would be that ARPA would continue to operate, if NASA is created, on the programs and the projects that are already underway?

Dr. YORK. Yes, sir. Well, I do not know if we are quite together or not. What I would do is to continue with ARPA as a permanent arrangement for handling the Department of Defense programs and requirements in space, that ARPA would coordinate and carry out within the Defense Department the programs which are, as the bill says, peculiar to or primarily military in nature, and I would certainly hope that the law were interpreted in such a way that that allows, in addition, research and development and was not narrowed in terms that all we could do was hardware systems.

In the meantime, we have a number of programs started. These can either continue under our direction or be transferred to NASA and I think the only criterion should be just simply whether they can be transferred in such a way that they do not lose any momentum.

I rather imagine that those things which are not too far off, such as the lunar problems and the other space science vehicles that we have already emphasized for ABMA and AFBMD, that we keep those.

Others which are further off, even though we start them, would presumably be transferred over at an appropriate time, as soon as the new Agency is capable of picking them up.

Mr. NATCHER. Do you favor a 17-man Board, Dr. York, or would you be in favor of a Board containing a smaller number?

Dr. YORK. I worked for the Atomic Energy Commission for many years up until a month ago and I am more familiar, so to speak, with the small and continuous Board that the Commission represents as opposed to the very large and occasionally meeting Board that is mentioned in the Board. That is where all my experience lies.

I like that way of doing things. I really have not seen enough of the other way to know that the Commission is necessarily better, but I am quite satisfied that it is a good way.

Mr. NATCHER. Dr. York, assuming that NASA is presently the law, we have the other agencies that we refer to from time to time, not only in our military services but otherwise that are doing considerable research work.

What suggestions do you have to make that should naturally follow after passage of this law insofar as they concern exchange of scientific knowledge, accomplishments, and achievements here in our own Government and in our own country, and insofar as they concern exchange between the different agencies, your Agency and the other agencies, the military services included?

Dr. YORK. Between us and other agencies doing similar work we would do it by what amounts to a continuous liaison, either formal or informal, just simply having our technical people get together with their technical people.

That will hapen on an informal basis. Where the coupling is very close, then probably one would set it up on a formal basis.

Mr. NATCHER. Do you feel, Doctor, that we have proper exchange of scientific knowledge today with our allies?

Dr. YORK. We could always have more. There is a growing problem. It has to do with the fact that information is being produced at an ever-accelerating rate.

I don't have any ideas on what to do about it. I know it is very easy to get behind in information even in a very narrow field because there is such a rapid generation of information.

Mr. NATCHER. Do we have too much classification so far as scientific matters are concerned?

Dr. YORK. I am certain with the enormous amount of classified information we have that some of it is probably overly classified and could be declassified.

I do not feel that there is a heavy preponderance of overclassified information. I am certain there is some. I run across it from time to time.

Mr. NATCHER. You are confronted with that from time to time in your present agency?

Dr. YORK. Well, yes. None of us, of course, has any important trouble getting information. On the other hand, there is information which would be of more general use.

When that comes along and we are aware of it, we try to do something about it. I am in the process right now of trying to get some things declassified in the next week or so.

Mr. NATCHER. Thank you, Mr. Chairman.

The CHAIRMAN. As a matter of fact, good leadership on the part of the Nation would be to let the world know, where it can probably be done, of discoveries and information, not only in this field but in all other fields?

Dr. YORK. Yes; certainly with any scientific information that comes from space and space satellites and so forth we should release it just as soon as we can.

I believe that is what we will do. I do not foresee any problem there. I think we will release what we get as soon as we get it.

Mr. SISK. Dr. York, how close has your association been with NACA?

Dr. YORK. In the last 3 or 4 months it has been fairly close with the top levels of NACA. I have never worked very closely with NACA as such.

I have known, personally, Dr. Dryden and General Doolittle for 4 or 5 years, usually because I was on some committee or other which they are also on.

Mr. SISK. My questions do not reflect any necessary criticism of NACA. However, as I suggested to Dr. Dryden the other day, it seems to me, of course, had they been the proper vehicle for this particular job, then there would not be any point of us worrying and trying to create another one.

Are they under direction now? I am referring to the Office of Naval Research under Adm. Rawson Bennett.

Dr. YORK. No, they are not.

Mr. SISK. Are you familiar with the work of the Office of Naval Research under Admiral Bennett?

Dr. YORK. Much of it.

Mr. SISK. How familiar are you with it over a period of years and the attainments of the Office of Naval Research?

I am speaking now back even to the Second World War.

Dr. YORK. I have seen bits and pieces of basic research that they have sponsored. I have been familiar with the Naval Research Laboratory for a half dozen years, I think, with some of the aspects of the Naval Research Laboratory.

Mr. SISK. Are you in any position to appraise, on a comparative basis, the attainments, let us say, of the Office of Naval Research as compared to NACA?

Dr. YORK. They are not very easy to compare because they are in quite different fields. The Office of Naval Research also does a great deal of research, has sponsored a great deal of university research by contract which NACA does not have anything to correspond. Very roughly they are comparable.

I do not know which I would say is better.

Mr. SISK. I realize there is no comparison in the amount of money. Of course, NACA gets some pretty substantial amounts of money.

The Office of Naval Research operates on a very nominal budget. I was interested, in view of some things I have heard and the few things I know, as to your comparison because I think the Office of Naval Research has actually made some substantial progress in the field which we are discusssing today as well as in other fields on, let us say, a far less amount of money than NACA has to play with.

Again, I am not being critical.

Dr. YORK. Are you including the Naval Research Laboratory in this or not?

Mr. SISK. To just what extent it works under Admiral Bennett at the present time as a part of the Office of Naval Research; yes.

Dr. YORK. Well, they have done good work. There is good work in both of these places, both NACA and ONR. It is difficult for me to compare them both on the basis I know, and perhaps I know them too well personally to make a good comparison.

Mr. SISK. I have no intention to put you on the spot, Doctor. Frankly, I might say that there have been things that would indicate that there has been a great deal of delay sometime in making decisions

on the part of NACA. Scientists and others have not had the free rein that they probably should have under NACA as compared to what perhaps a similar man would have had under the Office of Naval Research.

As I say, maybe I am in error on some of those positions. That is the thing that causes me to be concerned about the setting up of this new agency, if we propose to use, let us say, as an example or prototype, the NACA and then have an NASA to take its place.

I believe your statement in answer to one of the other gentlemen indicates you would not object to seeing a commission instead of the proposal in the bill.

Dr. YORK. That is where my experience lies and I am convinced that is a good way to do things. That is a positive statement about the Commission rather than a negative statement about the Advisory Committee.

Mr. SISK. I appreciate that.

Mr. O'BRIEN. You obviously feel that basic research has not been stifled when it has been performed under the military tent.

Dr. YORK. I think sometimes it has. I did not mean to say it has not been stifled at all.

Are you referring to the answers I gave on the question of classification?

Mr. O'BRIEN. No. What I had in mind is the sentence you had in your statement. You said:

> Even when space was unpopular and something to hide under the table, the Department of Defense was active in studying its potentialities and had many small projects in being.

The point I am trying to make is that if it had not been for the encouragement of basic research by the military we would be in pretty bad shape today.

Dr. YORK. That is very true. On the other hand, there is always room for improvement, too.

Mr. O'BRIEN. I understand. A great many people think there is a conflict between the military and the scientist and that the military does not encourage the scientist. Obviously they have, from your own statement.

Dr. YORK. Yes. There are a lot of personal opinions on that. I do not feel that there is this conflict that some other people do feel there is.

Mr. O'BRIEN. Mr. Fulton.

Mr. FULTON. I am glad to see you here, Doctor. Obviously, under the appropriations system of Congress, for the military whatever basic research has been in the program has been smuggled under the table because there has been no money appropriated to these agencies in the military for that purpose.

Dr. YORK. Not for any specific purpose, but in the service laboratories there is always a certain amount of freedom allowed the better people to do some thinking of their own. That is where these things were born.

Mr. FULTON. But it was you people who made room for it in your budget?

Dr. YORK. Not ARPA. We are only a month old.

Mr. FULTON. I mean the military people.

Dr. YORK. Well, made room for it, yes, allowed it, whatever you want to say.

Mr. O'BRIEN. Bootlegged it a little bit, perhaps.

Dr. YORK. That term is sometimes used. No doubt in this field there was a certain amount of bootlegging.

Dr. FORD. If I may, I would like to correct the record. Out of approximately \$700 million appropriated in fiscal 1958 for research and development in the 3 services, I would venture to say that for the 3 services in accumulative total there is probably a minimum of \$200 million used in basic research, according to their own testimony.

Dr. YORK. It is hard to define "basic research," of course. It is like the question: Who is a liberal? You can't settle that question.

Mr. FORD. Yes, but there is a considerable amount of money and a sizable number of projects which could legitimately be called basic research. It is not as much as the military would want for basic research and, certainly, not as much as the scientists themselves want, but there is ample testimony in the hearings over the last few years that a substantial portion has been used in basic research in one sort or another.

Dr. YORK. Yes; there is a considerable amount. There is always room for improvement, but there is a considerable amount.

Mr. FULTON. I think we want to see the military have an opportunity for basic-research programs in their programs that are, under the proposed legislation, restricted primarily to military weapon systems.

Dr. YORK. We in ARPA are looking into the question of in what area is there too little in the way of research and are beginning to identify some and hope to get on with them.

Mr. FULTON. That is why I asked you, in connection with the gentleman's question, for better language to assure that just this thing will be taken care of in the future.

Dr. YORK. I am not enough of a lawyer. I could interpret it in such a way that would make it broad enough now, but I suppose somebody else could do it some other way.

Mr. FULTON. You have projects on the shelves of ARPA now that you believe are practical. How many projects, in number or size, are there that are sufficiently practical so that, if you had the ability to go ahead with it and instructions to go ahead, you could do? Are you being held back much on the plans and programs you have because Congress and the American people are not being awakened to what you are going?

Dr. YORK. I think, right now, we are probably being held back, if it is fair to say we are being held back. There are two reasons.

Mr. FULTON. You would say that, first, you are being held back in ARPA?

Dr. YORK. Or we are holding ourselves back. We are very new. We are still getting our people. As far as the ARPA staff is concerned, we now have one kind of string or another on what we regard as a sufficient staff for going ahead, but they are not here. It will take some time for us to get them here. It will take some time for us to get oriented. One of the reasons we are being held back is the fact that we are very new and are still trying to develop our capability.

Mr. FULTON. Take, for example, the million-pound-thrust engine. You could be expanding your studies tremendously on that if you had $15 million to $25 million to begin with, instead of $500,000 annually.

Dr. YORK. Yes.

Mr. FULTON. Is that not right?

Dr. YORK. That is quite right. The other thing holding us back is that, since there was no ARPA at all, it was hard to appropriate money to ARPA, and there was $10 million appropriated in fiscal 1958.

In the next fiscal year, there is around a half billion dollars, but the fiscal year does not start for 3 months yet. So, we are held back, if you like, both because we are new and don't have people, and, also, because we are new and don't have a fiscal 1958 appropriation.

Mr. FULTON. The question is: Do you have room to put in your budget the research that is necessary for lunar shots, million-pound-thrust engines, a third-of-a-million-pound-thrust engines, ion propulsion, photon propulsion, nuclear propellents?

Dr. YORK. We don't have room for everything under the sun, but we have room for most of the things you mention. We do have room for a million-pound engine. We do have room for lunar problems and so forth.

Mr. FULTON. Do you have room for the development of this intercontinental travel and this intercontinental capsule freight transmission or the shot proposed by Von Braun to put a man 150 miles into the air?

Dr. YORK. We can do some combination of these things.

Mr. FULTON. Which would you leave out?

Dr. YORK. I am not prepared to answer. For instance, several of the things you mentioned have to do with what we refer to under a general title of "Man in Space." What we intend to do jointly with all 3 of the services and with NACA is to study the some 60 proposals that have been made for "Man in Space."

There are not really 60 different proposals, but there are a half dozen which are different. We propose to study those, review them, try to see which ones make the most sense with respect to such items as time scale, cost, pertinence to long-range objectives, reliability, and so on, and then institute a program to get a man in space. There are quite a few alternatives for the short term. You mentioned Von Braun's proposal on what is called the Adam program. That is the flight of two men in Redstones.

Mr. FULTON. I think it has been renamed, since this committee started, "The Woman Being Shot From the Gun" program.

Dr. YORK. Perhaps so. The last name I am familiar with is the Adam program. This has to be evaluated against other ways of finding out information.

The question comes up: Which ones are more pertinent in the long run?

The Adam program does put a human being into space, but it only puts him in for a very short time and, as it is proposed now, only two.

The alternatives to that sort of thing are, first, to put animals into orbit and study both the psychological reactions of animals, and for

a much longer time. Animals being lighter than men, they can be put into orbit much sooner than man can, simply because the capability for putting them up, that is, the requirement for thrust, is less.

Also, of course, the requirement for safety is considerably less, too. Of course, we do not necessarily have to choose between one or the other. It is possible to do them both.

Mr. FULTON. Our point on this committee is that there are some of us who want to go ahead with a space program on an accelerated basis and on a much broader basis, first, for security, and second, for exploration, and, third, to encourage the tremendously expanding space industry. How do we do it? We want you people to think broader, and maybe Congress, itself, will raise its sights.

Dr. YORK. Incidentally, I would hope that there would be more money for space matters next year than there is just in the ARPA budget. I would hope that NASA would have a sizable budget of its own for carrying out programs that are primarily civilian on its own and to combine with funds of others for programs that might be of joint interest.

The CHAIRMAN. Assuming you have the money, what kind of space program do you see for ARPA?

Dr. YORK. ARPA has not tried to lay out a complete national space program because the NASA, presumably, is coming along. Roughly speaking, the space program that we have laid out consists of, first of all, the things already going on. There are 4 space vehicles that we authorized for ABMA, including 2 lunar probes. There are the three lunar probes we have authorized for the Air Force Ballistic Missiles Division.

These are nonmilitary in objective. In addition, as a continuation of that, we hope, in conjunction with requirements and priorities established by the National Academy of Sciences and the National Science Foundation, and the NACA, to set up a continuing program of some reasonable number of scientific space vehicles per month.

I don't know what is reasonable yet because on the scientific side the Academy people and that group have not yet really made a positive indication of what they think there ought to be.

We are still in the process of trying to find out what the costs are to put one up. We don't know the number of satellites per dollar and so forth, but I imagine one per month or every month for purely scientific purpose might be a reasonable number.

Mr. FULTON. How can we in Congress on these space programs increase the proportion of thrust to drag? How can we get it moving faster?

Dr. YORK. Well, pass the 1959 budget, I guess, is the first item.

Mr. FULTON. Would you put in the record your method of deciding jurisdictional disputes at present between ARPA and the NACA, the policies you are using?

Another thing is this: Supposing this committee recommends the establishment of an agency, a separate agency in Government, to have the primary responsibility for implementing a glossary or dictionary of scientific terms that will be official for the whole United States Government, where would you put that?

Dr. YORK. A glossary of scientific terms that would be official?

Mr. FULTON. Where would you put the agency? Who should do it?

Dr. York. I do not really much care. If you want it done right now, it has to be done within the Department of Defense probably.

Mr. Fulton. Should there be a separate division of NASA to do that or should it be over in the Library of Congress?

Dr. York. I don't think it is that type of job, a separate division of anybody. You can get a couple of people together who know these terms and then they can go around and ask more people, "What should you like to put in here?"

Mr. Fulton. But it should be done, should it not?

Dr. York. Well, I suppose. I don't even get excited about it.

Mr. Fulton. I have heard scientists use terms here that do not equate with the other scientists' use of terms. For example, I heard one of them use air for atmosphere and atmosphere for space.

Dr. York. I am sure it is worthwhile. I just am not very personally excited or interested. I am sure it is worthwhile.

Mr. Fulton. On this translation of documents from foreign countries, should we have a special agency set up by this committee in Government to have the overall responsibility for the Government and every agency in it for making translations on space and basic scientific research materials?

Dr. York. Certainly such translation should be made, indeed. I do not know whether this committee should get into it or not. It could be handled either by the NASA or we in ARPA could find somebody to handle it.

Mr. Fulton. I was really asking you what agency should handle it rather than whether any congressional committee should handle it.

Dr. York. Well, it could be handled by the Science Foundation or there are quite a number of groups interested in the translation of scientific documents at this time.

The Science Foundation is one group. ONR is another. In a particular field like this the NASA could do it.

Mr. Fulton. I understand that the Library of Congress at present is not able to keep 1 out of 6 volumes it would like to keep in related fields, the fields we are discussing on space. So should that not be expanded?

Dr. York. I think it probably should.

Mr. Fulton. How do you make available generally, to the companies participating in these programs the materials that would be of a scientific nature which would help them on their contracting?

Dr. York. You mean information?

Mr. Fulton. Yes. How could we get a system of distributing that around the country, particularly in relation to small business.

Dr. York. I really do not know how to do that.

Mr. Fulton. You see, so much of it is classified that it keeps many small businesses out of the program.

Will you submit a statement on the record for that?

Dr. York. I don't know how long it will take me to submit a statement on that.

Mr. O'Brien. Dr. York has to get a plane at 6. I understand in spite of scientific accomplishments, to get to the airport you still depend on gasoline propulsion?

Dr. York. Yes, sir.

The CHAIRMAN. Doctor, in response to my question on the space program conceived for ARPA, I don't think you completed your answer, on the rest of the ARPA program.

Dr. YORK. Yes. I had discussed essentially the programs we had already specifically authorized and then the fact that we are working on a continuation of such a program.

The CHAIRMAN. Can you give us an idea of what that continuation is?

Dr. YORK. I mentioned perhaps one a month or perhaps every other month or something like that. We do not yet have a picture. We don't have, yet, what you might call a requirement from the IGY or the people who will follow the IGY.

In addition to that, we are planning component development programs. The million-pound-thrust engine is one such component development program.

The development of special stages to go on top of our big rockets is another. That is, as has been pointed out here quite a few times, it is not just the matter of a thrust in the bottom stage, but it is what goes on top, too. So we are planning development programs on having better higher performance, higher stages for rockets as well as developing larger lower stages.

We are planning development programs in special components of other sorts; that is, better telemetry systems, better power supplies.

There are a great variety of power supplies for use in space. Both chemical batteries and solar batteries are now being used but both of those can be improved.

There are also reactor power supplies, there are radioactive isotope power supplies, there are solar boiler power supplies and so on.

We are planning a review of that field and then initiation of research and development in various and sundry power supplies suitable for space.

Various new guidance and control systems for midcourse and terminal guidance in connection with getting into precise orbits are being planned.

You know the satellites that are now in orbit are in orbits that are very inprecise, big loopy elipses that are not nice circles and so forth.

We are planning developments of components of that sort. Then we plan again to first review requirements and review the possibilities in a group of possible fields of application, practical application of space.

The ones that were mentioned several times this afternoon, I am sure, communications, meterology, weather reporting, navigational aids, things of that sort, which are of military interest as well as civilian interest, and in many cases the military interest is different from the civilian interest.

You might have satellites which are not just simply relays. I mean one way of having a communication satellite is to have a satellite at some very high altitude, perhaps the one that stands still, use it by simply beaming up and receiving radiation back. That is one possible kind of satellite communication relay. That obviously is not very secure, I mean, anybody can hear what it says.

You could, of course, code it, but anybody could hear it.

Another kind possibly is the one that is sort of like the mailman that has been discussed here, too, where you put information in it at one point and it goes over another one and then you take the information out.

In connection with meteorology, the military interests are different from the civilian interests. The military is always interested in such matters as strike information, for instance, and in connection with the possibilities of nuclear war would be interested in the question of which way the wind is blowing in the target for fallout prediction purposes and so on.

Other programs and actually bigger programs, but programs which I think we should not discuss here, considerably bigger programs, are programs in the use of satellites for strictly military purposes, early warning reconnaissance and so on.

One of the things incidentally in all of the discussions that makes it look as though the civil program is where all of the interest lies is because you cannot talk about the military program. But it is a sizable program. That part of the iceberg that is under the water is the large part.

The CHAIRMAN. Is biological and chemical activity involved?

Dr. YORK. Man in space is a part of the program that we hope to get going. That includes biology, but of a rather special sort. There are really two almost independent branches of what you might call space biology.

There is one which is the human reaction to space, which is important for human space flight, I mean the physiological and psychological reactions of man to weightlessness in particular and acceleration on the way up and perhaps environmental problems. But I think the weightlessness is the overwhelmingly important one and the other biology, the regular biological research where you investigate the organisms under weightlessness where you go to see if there is life on Mars and things of that sort.

These are not of direct military interest. They are not necessarily of interest in connection with military applications.

They might very well become interesting. Nearly any kind of research can lead to results which are a defense interest.

Now, I think I have covered this especially by putting in that big miscellaneous of the special military program.

Mr. FORD. I happened to have heard Dr. York before another committee yesterday and I will forego questioning because of his time problem.

Mr. O'BRIEN. We all appreciate your time problem. We are very grateful to you, Dr. York, for your contribution to the record.

The CHAIRMAN. Not only his knowledge, but his simplicity as well.

Mr. FORD. May I make a suggestion, Mr. Chairman?

Dr. York, is there any objection to the insertion in our record of this chart you submitted to us yesterday showing the organization of ARPA?

Dr. YORK. No, sir.

(The chart above mentioned faces p. 60.)

The CHAIRMAN. I have one more question

In the line of command in ARPA in connection with the Defense Department, are you finding a pleasant, cooperative, understanding, fertile atmosphere, whatever you want to call it?

Dr. YORK. Yes; so far, so good. It is still a somewhat new situation but it shows promise of working well.

The CHAIRMAN. Do you run up against lines of resistance in going through too many steps to get action?

Dr. YORK. Sometimes, perhaps, it seems that way, but then one must recall that ARPA is brand new and nobody over there knows whether we can really be very effective or not.

So it is very natural to expect that people are looking over our shoulders at the present time. But it looks to me as though it will be a situation that will work out very well.

The CHAIRMAN. We know about the difficulties in bygone years. I was on a subcommittee that looked into research and technology in the Defense Department back in 1954. There are a lot of equations in human beings but sometimes they are exaggerated to a harmful extent.

Have you found that has been corrected to some extent?

Dr. YORK. Of course, I do not know how it was. I do not know as well as you do how it was. I have been in and out of the Defense Department in the last few years.

I don't know if it has been corrected or not. However, I do have a good degree of confidence, speaking personally, that things are moving in the right direction over there.

Mr. O'BRIEN. Again, thank you, Dr. York.

The committee will meet tomorrow in room 219 in this building at 10 a.m.

(Whereupon the committee recessed at 5:10 p.m., to reconvene at 10 a.m. Friday, April 25, 1958.)

ASTRONAUTICS AND SPACE EXPLORATION

FRIDAY, APRIL 25, 1958

HOUSE OF REPRESENTATIVES,
SELECT COMMITTEE ON ASTRONAUTICS,
AND SPACE EXPLORATION,
Washington, D. C.

The committee met at 10 a. m., pursuant to recess, in room 219, Old House Office Building, Hon. John W. McCormack (chairman) presiding.

Present: Representatives McCormack, Brooks, Hays, Metcalf, Natcher, Sick, McDonough, Fulton, Keating, and Ford.

Present also: George J. Feldman, director and chief counsel

The CHAIRMAN. The committee will be in order.

We are very happy to have with us three distinguished gentlemen this morning as witnesses. The first witness is Dr. Clifford C. Furnas, chancellor of the University of Buffalo.

Doctor, we are very happy to have you with us. Have you a prepared statement?

STATEMENT OF DR. C. C. FURNAS, CHANCELLOR, UNIVERSITY OF BUFFALO

Dr. FURNAS. I am sorry, Mr. Chairman, I do not have a prepared statement.

The CHAIRMAN. All right. Everything is informal. I like informality in committee hearings rather than formality. You may proceed in any way you want. As far as the committee is concerned the more informal it is the better we like it.

Dr. FURNAS. Thank you sir.

The CHAIRMAN. We shall be glad to hear you, Doctor. By the way, each one of the witnesses will have the opportunity of editing his testimony. You may clarify or add thereto or, if upon reflection, you think of something that you feel might be helpful to the committee in its hearings that you did not cover in your testimony or under questioning, you may include that in your revised remarks.

All right, Dr. Furnas.

Dr. FURNAS. Mr. Chairman, ordinarily one gives a biographical statement at the beginning of the testimony. I might say that I was for a period Assistant Secretary of Defense for Research and Development, from November 1955, to February 1957.

If it is satisfactory with you, Mr. Chairman, I will simply leave a biographical statement for the record and then proceed.

(The record is as follows:)

Brief Biography of Dr. Clifford C. Furnas, Chancellor, University of Buffalo

Dr. Clifford C. Furnas was born October 24, 1900, at Sheridan, Ind. He holds the degree of bachelor of science, with honors, from Purdue, 1922; of doctor of philosophy from the University of Michigan, 1926; and of honorary doctor of engineering from Purdue, 1946; and from the University of Michigan, 1957. While in school he was a long-distance runner of distinction, and competed in the 5,000 meter event at the Olympic Games in Antwerp in 1920. In 1922 he was awarded the Big 10 Conference medal for the best combined scholastic and athletic record.

He has always had a sustained interest in both research and education and his working career reflects this duality. From 1926 to 1931 he conducted research work on metallurgical processes at the United States Bureau of Mines at Minneapolis, Minn. In the latter year he joined Yale University as associate professor in chemical engineering. In 1941 and 1942 he worked for the National Defense Research Committee, coordinating a large research and development program. He was appointed by Curtiss-Wright as director of its aeronautical research laboratory in Buffalo in February 1943. This laboratory was given to Cornell University on January 1, 1946, and he became director and executive vice president of Cornell Aeronautical Laboratory. He assumed the post of chancellor of the University of Buffalo, September 1, 1954. On December 1, 1955, Dr. Furnas was granted a leave of absence by the university to serve as Assistant Secretary of Defense for Research and Development in Washington, D. C. He returned to his University of Buffalo post, February 15, 1957. For a number of years he has been an active member of various technical boards and panels for the Government, particularly in the Department of Defense.

While Dr Furnas has conducted a great deal of research in the fields of process metallurgy, he has specialized in and has written many technical articles on chemical and chemical engineering subjects as well as on phases of research related to aviation. In addition to technical and educational articles he has written several books, including America's Tomorrow (1932); The Next Hundred Years, a Book-of-the-month Club selection in January 1936; Man, Bread, and Destiny, written with his wife, S. M. Furnas (1937); and The Storehouse of Civilization (1939). He was editor of the sixth edition of Roger's Manual of Industrial Chemistry (1942). He was also editor of the Industrial Research Institute monograph on Industrial Research—Its Organization and Management (1948).

He is a member of Theta Chi, social fraternity, various honorary fraternities, social clubs in New York and Washington and of several scientific and engineering societies. He is a registered professional engineer in the States of New York and Connecticut.

Mr. Keating. I might add at that point, Mr. Chairman, that we in western New York are very proud to claim Dr. Furnas from our neighboring city of Buffalo. It is almost surplusage to include a biographical sketch of such a distinguished American.

The Chairman. The sketch is only necessary for the record. If I were a judge and you were appearing as an expert witness you would qualify without the necessity of establishing proof.

Dr. Furnas. Thank you, Mr. Chairman.

In lieu of a prepared statement which I simply did not have time to put together, I thought I would excerpt some material from a talk which I am going to be giving to the Air Force Office of Scientific Research Symposium on Astronautics in Denver, next Monday.

With your indulgence I would like to go a little bit into my own background thinking in approaching the matter of an appropriation for space exploration. I hope it does not seem to be extraneous.

So if I might proceed with some excerpts from this talk:

Why go to the Moon, or Mars, or Venus? At the present time there are probably five good reasons. Arranged in the order of prominence in the public mind, they are:

1. International prestige.
2. Possible military advantage.

3. The spirit of adventure.
4. The possibility of practical technical advances.
5. The thirst for knowledge—the desire to learn more about the cosmos.

This is not necessarily the most logical or most virtuous order of importance, but I believe the list does represent the present relative rating which a public opinion poll would reveal.

Whatever may be the impelling reasons, it now appears quite certain that, within the next few decades, man is going to explore space—at least within the solar system—very assiduously.

The United States space program will not only be complicated. It will be expensive. Now that we are faced with it, three questions come to mind:

I. Is there real justification for that support?
II. How should it be organized?
III. What will be the long-time results?

The first question, Can continuing support be justified? My remarks on this are tying in the military activities with the possible byproducts for civilian benefit. May I present a little bit of background on the byproducts of military activities.

Despite the destructiveness of wars, military activities have often, though sometimes inadvertently, led the longstanding human benefits.

Until the end of the 18th century mechanical goods were fabricated on an individual basis. Each item was practically custom built. In 1800 Eli Whitney (inventor of the cotton gin) obtained a contract from the United States Government for a substantial quantity of muskets.

After a full quota of difficulties, he produced them at his little water-driven mill at Whitneyville, Conn., with truly interchangeable parts; and he effectively reduced the technique to practice.

This was the necessary and sufficient background for the establishment of the mass production of duplicate mechanisms. Be it noted that this step, which was one of the key landmarks of industrial civilization, was born of a military need.

I can mention many others. For instance, the conquering of yellow fever, because of the work in the Army of Maj. Walter Reed; the fixation of nitrogen by the Germans immediately preceding World War I which is now our source of artificial fertilizers which keeps the world from starving to death; and the invention of the airplane would still be just a rather interesting device were it not for the support of the military throughout the last 40 years.

Had it not been for the support of the military for military purposes we would even now I am sure not have safe commercial aviation. Coming to World War II, the great acceleration which was given to the production of antibiotics, particularly penicillin, was one of the things caused by the war needs and has been of benefit, of course, to hundreds of millions of people.

There was a somewhat similar development in the form of synthetic rubber, although synthetic rubber was highly unsafe until the mass production method for making it was developed during World War II because of military necessity.

Then, of course, radar, which has a tremendous amount of civilian application, was the result of war activities, and then most striking of

all is the nuclear energy which arose from the military aspects of the atomic bomb.

I might add, perhaps parenthetically, it is fortunate in the 20th century we did begin using atomic energy for destructive purposes because it is my opinion the only way we will be able to supply the necessary energy for the world by the year 2000. Had we not done this in the middle of this century we would be in a very difficult situation throughout the world some 50 years from now.

The CHAIRMAN. Why do you make that statement?

Dr. FURNAS. Because in 50 years from now the world is going to need, and hence demand, manifold as much energy for the industrial production as we have now, and it is not going to be supplied by our fossil fuels—coal, oil, and gas. Perhaps I am wrong by a few, but not many, years.

Now these few examples from scores of possible ones leave no doubt that military developments have in the past led to many profound peaceful benefits and can well continue to do so in the future, even at an accelerated pace—if we but put our minds to the task.

Such byproduct benefits are one of the uses of adversity. If the national research and development program is planned and carried out with the secondary public benefits in mind, large continuing expenditures are well justified, no matter what may be the course of their national events.

Moreover, the program will make sense to the public, and the public will be willing to provide all reasonable support. The second question, What should be the organizational pattern?

The dual structure of military and civilian participation in affairs dealing with national defense has been fundamental in our national organization from the beginning. It is a sound pattern, but it does have its difficulties and its points of indecision. One of the debatable points is always: Should a particular activity be under military or civilian control? That question is now being debated in connection with the research and development program for the exploration of space.

In 1915 the NACA (National Advisory Committee for Aeronautics) was established to aid and advise the Nation in the basic and applied aspects of the then infant science of aeronautics. It was an entirely civilian agency. It has always remained so, even though a very large proportion of its work has been directed toward military applications. It has worked very well indeed. Its impact on both civilian and military aviation has been profound and outstanding.

The Atomic Energy Commission is a similar case. Although, immediately after the end of World War II, the paramount interest in the atom was for military purposes, it was realized that nuclear science would, and should, have impact and importance in many nonmilitary areas.

Hence, after considerable acrimonious debate, the AEC was established as a purely civilian agency. After appropriate liaison and coordinating bodies were set up between the military and civilian facets, it, too, has worked very satisfactorily. Should the same pattern be followed for the exploration of space?

The present proposal which is being considered by Congress is for the establishment of a National Aeronautics and Space Agency, which

is to be the focal organization for research for both military and civilian space projects.

This new organization would absorb the present National Advisory Committee for Aeronautics. I can best summarize my own reaction by saying I think this is an excellent idea. The scientific competence and administrative structure of the NACA is a most appropriate base from which to build the expanded activity. Such a move avoids setting up a large new governmental agency of which there are already quite enough.

The operating pattern and tradition of NACA practically insure effective coordination and cooperation with the Military Establishment. At the same time, civilian interests will be handled sympathetically and will receive adequate attention.

Discussions of the establishment of a new agency always proclaim an open season for objections and suggestions. I would like to make my contribution with one suggestion on what I believe to be a significant matter. I believe it is most important that this new agency, the NASA, should, as compared to the NACA, have expanded authority and liberalized policies for the support of research by outside agencies.

Certainly scores of excellent research laboratories in universities, research institutes and some industries should be supported by contracts in contributing research knowledge to the multiheaded problems of space.

If this aspect is not adequately handled, the national program will be greatly weakened. There is always the tendency, even if not the intent, for large Government organizations to become monopolistic. This tends to freeze out great blocks of talent, new ideas, and appropriate competition. Further, it seriously shrinks the reservoir of manpower from which future research talent can be drawn. I trust that adequate attention will be given to this important matter.

The CHAIRMAN. Have you looked into this provision of the bill from that angle?

Dr. FURNAS. I have not.

The CHAIRMAN. Will you do so?

Dr. FURNAS. I shall.

The CHAIRMAN. I think the language might cover it; but, on the other hand, I think you are addressing yourself to a point that I know meets response from me. In fact, I have considered that before. Now it is going to be really an operating agency.

It is quite a transformation, according to the concept of the bill. That is true, is it not?

Dr. FURNAS. Yes.

The CHAIRMAN. I think the point you have made is well taken. I would like you to examine the bill to see if the language is adequate to meet that situation.

Dr. FURNAS. I shall be very glad to do that, sir. If this new agency, the NASA, is established, how far should the Military Establishment be permitted to conduct or support research of more or less fundamental character in the general field of space technology?

Some very old arguments are being dusted off and put out on display. There are those who feel that the military organization should stick very closely to its knitting and only develop military hardware; that it should not broaden its operations to encompass anything

resembling fundamental explorations. There is still considerable feeling that it is not appropriate for the military to dabble in "scientific toys."

I feel that such arguments get the cart before the horse. If there is even a small probability that military weapons systems now or in the future are going to need some block of fundamental scientific information, which is not now being adequately sought for in some other quarter, then it is incumbent upon the Military Establishment to see that that general area is being adequately explored.

The exploration of space with all its ramifications, will unquestionably be an expensive, as well as a difficult, task. It is incumbent upon all concerned to husband the financial and the scientific resources as much as possible. This is going to make it even more necessary than ever to achieve a truly adequate coordination between the military and civilian programs.

The proposed reorganization of the Department of Defense, which also is receiving congressional consideration, can be a key factor in achieving the desirable pattern of action. President Eisenhower's statement that "separate ground, sea, and air warfare is gone forever" certainly has validity. It also points up the necessity of taking a good hard look at the organization, for all the military functions.

I would not presume to pass judgment upon the proposed changes in the operating command structure, but I do feel that the anticipated changes in the research and development area is a good step in the right direction. There are two important aspects of the proposed reorganization. First, the official in charge of the overall program (the Director of Research and Engineering) will have a higher rank and more well-defined authority than the present Assistant Secretary of Research and Engineering.

Second, this official will have at his command and available, certain funds and transfer authority which will permit him to initiate and control important research projects, particularly those which are of potential benefit to all three military services. This will give him a positive and constructive control which has been almost completely missing in the Assistant Secretary's Office in the past.

At present, the Assistant Secretary effectively has only negative control. The situation is roughly analogous to being responsible for driving a car but having access only to the brakes and not to the wheel and the accelerator. That is not a very satisfactory way to drive a car.

There are those who fear that the proposed structure will lead to too much concentration of power and that the desirable amount of competition among the services will be lost. Admittedly, a certain level of competition is desirable, but not the mayhem which is what we have been exposed to for quite some time. Even a football game needs a set of enforceable rules and an effective referee.

One of the major responsibilities of the new Department of Defense Research and Development organization, if it does materialize, will be the adequate planning and coordination of those projects dealing with space technology which can be carried out either by civilian organizations or the Military Establishment, or both.

This will be a difficult task at best but it can only be carried out effectively if there is adequate and well-defined authority, as well as responsibility, in the Office of the Secretary of Defense. Orderly

planning and procedure is going to be much more important than ever before.

The third question: What will be the longtime results?

Who could have predicted what Columbus would find when he sailed westward in 1492? By comparison, while we must admit that part of the crystal ball of space exploration is very cloudy, there are a few things which can be predicted with reasonable certainty.

It is reasonable to expect that before long we will have reconnaissance conditions, either manned or unmanned, which can continuously communicate a great deal of information about conditions on all parts of the surface of the earth. The military utility of such reconnaissance satellites is obvious.

It is also reasonable to expect that such satellites can be useful as practical relay stations for short wave communications over long distances. The development of anti-ballistic-missile missiles is very closely linked and perhaps should be an integral part of the space program. There can be no question of these military needs.

On the other hand, I find it impossible to generate any enthusiasm for the idea that artificial satellities, or the moon, could be militarily useful as storage places and launching platforms for guided missiles. Conceivably this might be possible but it would be the hard way to accomplish the military objective. Why do it?

If we should become thoroughly bemused with difficult accomplishments such as that, we could fritter away endless amounts of money and scientific talent. We will soon have guided missles of long range and great weight-carrying capacity which can reach any spot on the earth with far greater accuracy and infinitely less expense than any launched from artificial or natural space stations. Perhaps it is a sign of advancing age, but I do feel that enthusiasms should be tempered with a certain amount of judgment, particularly when very great sums of money and effort are involved.

Even though the space program has a very strong military impetus, the greatest yield in the long run may very well be from the indirect results. It will be difficult to predict what the applications may be; whether their greatest impact will be military or civilian. But, we can be quite sure that a number of things will be forthcoming. New knowledge nearly always finds a use—eventually.

One can visualize many developments in propulsion, especially in the field of rockets. Many basic and applied research programs are underway in the development of new fuels of greater energy content and greater specific impulse than the conventional hydrocarbon fuels. Various oxidizers for rockets are also under intensive investigation.

Since the conventional fuels and oxidizers, such as jet propulsion fuel and liquid oxygen, are marginal in their performance for getting into space, there will be greatly increased emphasis upon the development of the more exotic substances. The boron fuels which are under development for possible use in turbojets or ramjets do not offer any particular advantage in rockets, but these are by no means the only possibilities.

The most attractive fuel, of course, in terms of energy per pound, is liquid hydrogen. But its use is plagued with many practical difficulties. Its density is so low that it is very bulky, indeed. The very low temperature of liquid hydrogen leads to endless difficulties. It is hazardous to handle, unless extreme care is taken. These are

the kind of difficulties, however, that intensive development may be able to overcome. Fluorine has some distinct advantages over oxygen as an oxidizer. It, too, is a nasty substance to handle. But here again, intensive development may lead to practical solutions for its use.

Sketchy and preliminary measurements have established that the very nebulous atmosphere about 60 miles above the surface of the earth contains substantial amounts of monoatomic ionized oxygen. Oxygen molecules are ordinarily diatomic but in the rarefied high atmosphere the energy of the sun causes them to dissociate into single, ionized atoms.

When such atoms recombine, they release very substantial amounts of energy. Hence, studies are going forward on the possibility of using this atomic oxygen supply as the fuel for a ram-jet flying at those altitudes, at high speed.

This fuel supply would be inexhaustible so a ram jet propelled in such a manner could go on flying forever at this altitude, or until it wore itself out. The air at that altitude, of course, is extremely thin, the pressure being only about 3 millionths of an atmosphere.

Hence there is not very much atomic oxygen fuel per cubic foot and hence the thrust from such a device would be very small. However, the drag would also be very small and calculations indicate that such a ram-jet machine could fly, although it would have to be very light in weight. We need to learn more details about the condition of the atmosphere at those altitudes and then we need to try to get one of the devices up there to determine if it will fly as the calculations indicate it should.

Would this system have any practical advantage for either military or civilian use? Of course, we don't know. But, undoubtedly, we would learn a great deal. The knowledge would be applicable to research on free radicals of various substances that have some high energy fuel possibilities. Free radical research is one of the most interesting fundamental investigations that is going on at the present time.

Research in the development of nuclear rockets has been proceeding at a low level. This program, with the investigation of space in mind, will undoubtedly receive renewed emphasis. The first developments will be with nuclear rockets carrying some sort of a fluid to produce thrust. This will be necessary in order to develop the high thrust necessary to launch a device from the earth and accelerate it to very high speeds.

The second phase of the investigation will involve the thrust which may be developed from a nuclear rocket using only the nuclear particles of the active fuel itself The amount of thrust so produced would be very small but it could be long sustained. Perhaps this will prove to be the only effective way of developing adequate acceleration for true space travel. Will such developments have military or civilian application? No one can say with certainty but the chances are that they will.

There is a very good possibility that efforts such as these will, in the not distant future, lead to practical, rocketship transportation of men and materials between distant spots on the earth's surface. When that day comes, every spot on the earth will be within 2 hours'

traveling time of every other spot. This will be a tremendous step in man's advancement.

One can visualize a number of developments of new component devices which will eventually find great utility. One of the American satellites now orbiting overhead is using solar batteries of a new type to power its milliwatt broadcasting station. Solar batteries are in their infancy and space exploration is going to lead to their great improvement. One can visualize many applications which may be far more significant than merely powering portable radios.

Another approach to the satellite power supply for sustained instrumentation and broadcasting is the development of very small, compact, and effective nuclear powerplants. When such devices are perfected, will they have utility outside of satellites? They probably will.

Already many advances have been made in very compact and lightweight electronic instruments of various kinds in connection with the satellite program. The possibilities of utility here are very great, indeed.

Our thinking, however, would be very restrictive, if we simply confined ourselves to trying to visualize the immediate development of practical devices.

In the long run, the most appealing part of the exploration of space will be the acquisition of new, basic knowledge. One of the more intriguing fields of investigation is that of the terrestrial weather. What effect do the violent storms on the surface of the sun, and the sunspot cycle, have to do with the weather over the surface of the earth? It seems quite apparent that there is an effect, but how much and why? Do the ever-shifting magnetic fields around the earth and around the sun have some impact, particularly on the long-range weather cycles? When we acquire more fundamental knowledge about the solar and the terrestrial weather and their relationships, we will certainly be able to make better predictions which will be useful to a great many people.

If we are able to improve our predictions, will we eventually be able to control the weather if we should so desire? It is highly important that we try to arrive at the answer to that question.

Even now, very early in the game, our quite small satellites have yielded considerable new data on cosmic rays, those rather mysterious high-energy radiations which constantly bombard us from outer space. Just what are the makeup and the characteristics of the primary cosmic rays? Where do they come from? What do they signify? Some have said that they are the birth cries of atoms; others have said that they are the death cries of atoms.

Perhaps they are both. Be that as it may, these fringes of outer space constitute one of the most effective laboratories for the study of nuclear phenomena, provided we can get adequate experimental apparatus there and maintain it. Directly, and indirectly, we are going to learn a great deal more about the fundamental structure of matter and what the nucleus really is and how it acts.

As a Cornell professor recently stated it, "Researchers studying the source of cosmic and radio waves in space and those trying to produce controlled nuclear power are traveling the same scientific wavelength." Such knowledge may turn out to be the key to the effective and practrol of fusion (the hydrogen bomb reaction). When and if this

occurs, we will have found the way of supplying essentially an infinite amount of energy for human use on the face of the earth, for all time to come. We trust that it will be used for peaceful purposes.

Although I can see no reason for attempting to use the moon as a weapon carrier, I think it still might be very useful to us. Some day we will get there. It would make a marvelous stable platform, without any interfering atmosphere, for an astronomical observatory. If such a station could be established, the results would add greatly to our knowledge of the universe; how it is put together and how it ticks.

It would be very interesting, indeed, to have some solid samples from the moon. They won't consist of green cheese but they might be just as palatable to scientists. We might learn something new about the evolution and the concentration of minerals.

If we should get to Mars, and if there is plant life there as many people believe, we would add greatly to our knowledge of the penomena of living matter itself. If there is life there, it has certainly evolved under quite different atmospheric and other physical conditions than on earth. Would such new samples, which arose from very different conditions, give us some intellectual leads to common and basic phenomena of the chemical kinetics of living matter?

It is a very interesting speculation. When we do learn more about the basic facts of life, we almost certainly will make still further improvements in human health. It is not hard to visualize many other applications which ultimately will improve human welfare, when the living cell is no longer a mysterious and misunderstood blob of matter.

I want to summarize by saying that for our own immediate military welfare and for ultimate human advance it is highly important that we get to the moon and beyond.

The CHAIRMAN. Doctor, the bill provides for an organizational setup under a Director, as you know. Have you any opinions to express as to that type of setup or Commission type?

Dr. FURNAS. I am not sure I understood you, sir, as contrasted to having it under a Director or under a Commission?

The CHAIRMAN. Yes.

Dr. FURNAS. In general I feel this type of setup should be under a Director, that there should certainly be a guiding body very much as the present National Advisory Committee for Aeronautics.

It is that sort of structure which I think works very well.

The CHAIRMAN. The future field and jurisdiction of this Agency is broader as it is now and as it has been in the past; is it not?

Mr. FURNAS. The so-called NASA will have a broader field, yes.

The CHAIRMAN. I am exploring and trying to get the benefit of your views.

Dr. FURNAS. I do think the NACA structure has worked so well that it is one that can be used. Perhaps there will be some variations, but I feel the new structure should be modeled after that.

The governing board or the committee itself, which certainly guides the program, is made up of representation of the various key spots in the Government and also of outstanding national figures in the scientific field.

I think this makes a very sound, nonpartisan, guiding body which works effectively. It depends, of course, primarily on the character of the men that are there, but I think we will get such high character of men in such a governing body in that area——

The CHAIRMAN. Unfortunately, Dr. Dryden made a statement that the suggestion of Dr. von Braun was more or less a circus stunt like shooting a lady out of a cannon.

Dr. FURNAS. I believe that Dr. Dryden was referring to the von Braun statement, that within a year they could send a man 150 miles into space and bring him back, something like that, and Dr. Dryden said this was rather like a circus stunt, we would not learn anything.

I tend to agree—I don't know that I would make quite as vigorous a statement as that, but I tend to agree with Dr. Dryden on that.

I don't think there is a point to doing this with all the hazard unless we can learn something. If it is valuable to impress the Russians, in this way, then let us do it on this basis.

The CHAIRMAN. Out of that could come an awfully lot of good, the manned vehicle. There could be an honest difference of opinion on that.

Dr. FURNAS. I think there is an honest difference of opinion.

The CHAIRMAN. In your opinion, you would not refer to it as a circus stunt?

Dr. FURNAS. I would not.

The CHAIRMAN. Some of us thought that looked into the mind of Dr. Dryden, and it was only a slight piece of evidence, but you judge a person's mind by what he says and what he does; some thought that the statement indicated that he did not have an appreciation of the maximum possibilities to which that example was directed.

Dr. FURNAS. Knowing Dr. Dryden quite well, I don't think I have any trepidations about his imagination and constructive approach. I think all he was referring to was the fact that this would be premature until we had a great deal more instrumented flights.

The CHAIRMAN. What do you think of this 17-man board established by law?

Dr. FURNAS. I think I had probably better read the bill before I express an opinion.

The CHAIRMAN. You read it over and you express your opinion when you are editing your remarks.

Have you given any consideration to the possible international aspects of this field, international law, the sovereignty of nations in the outer space?

Dr. FURNAS. I have given no consideration to that, no.

I know it is the sort of thing that can be very complicated. I do know that there are various people who have been trying to express legal opinions of all the implications. I feel that the old analysis of freedom of the seas and freedom of the air are not going to be applicable.

I have formed no opinion as to what the legal aspects may be in the international scene.

The CHAIRMAN. I realize that that is a matter of many years of consideration and study and probably trial and error and the development of a code of international law and conduct, but I can see the possibility of one nation hitting the moon and claiming the moon within their jurisdiction.

Dr. FURNAS. I presume the claim is not valid unless it is occupied, however.

The CHAIRMAN. Well, it is according to who the nation is. I take it from your testimony that you have in mind the necessity of the military considerations involved, having also in mind the world of today and as far as we can project our mind into the future.

Dr. VURNAS. That is correct, sir.

The CHAIRMAN. Furthermore, there is an interrelationship there, anyway, is there not?

Dr. FURNAS. There is, definitely.

The CHAIRMAN. Furthermore, we have to, above all else, do those things best in connection with our country in connection with its preservation. Everyone has to face that fact, does he not?

Dr. FURNAS. That is right.

The CHAIRMAN. You refer to a number of incidents, of where something started out primarily as a military inquiry and has produced great peaceful benefits to mankind. Do you think there should be close relationship between any new agency and the Defense Department and the Atomic Energy Commission?

Dr. FURNAS. Yes, sir

The CHAIRMAN. In fact, all other agencies but those two, in particular?

Dr. FURNAS. That is correct, sir.

The CHAIRMAN. That could be done by representation on this board if it is part of the law, but also through the establishment of liaison groups where there would be the constant contact with one another and an exchange of views.

And, above all, there have to be understanding minds everywhere that appreciate the overall consideration of the national interest of our country?

Dr. FURNAS. Yes.

The CHAIRMAN. Mr Brooks

Mr. BROOKS. Doctor, I listened with a great deal of interest to your statement. I rather liked your approach to this problem. You make a very interesting statement and at the same time it shows definitely that it has ample substance.

I also like the apparent admiration that you have for the National Advisory Committee for Aeronautics. I worked with that Committee, too, for many years.

Does your university have projects in the handling of which they come from the Advisory Committee for Aeronautics?

Dr. FURNAS. No, at the present time we have no project with the NACA.

Mr. BROOKS. Have you had any such and have you had any experience with the way in which they handled these projects?

Dr. FURNAS I was formerly, until 1954, director of the Cornell Aeronautical Laboratory in which we had a few projects, not many, but I had a great deal of contact with the NACA because when I worked as Assistant Secretary of Defense, I was a member of the NACA ex officio.

Also, everyone that is involved in this NACA are personal acquaintances because of the activities of the Institute of the Aeronautical Sciences.

So I know the members personally and I know their work quite well as I have been on the subcommittee dealing with the subject matter for over a number of years.

Mr. BROOKS. You think the NACA is a well managed, efficient operation?

Dr. FURNAS. Yes, sir.

Mr. BROOKS. And it goes after the particular projects that it has in mind in a proper and efficient manner; is that right?

Dr. FURNAS. Yes, sir.

Mr. BROOKS. You had that experience as a member of the NACA Board. Do we have anybody from the Defense Department now on the NACA Board?

Dr. FURNAS. I have forgotten the makeup at the present time. General Putt, I think, is still on the Board, from the Air Force.

Mr. Foote, who was Assistant Secretary for Research and Engineering, is on there.

At the moment I am not sure who is on from the Navy.

The Army is not represented.

Mr. BROOKS. There is no provision in law with respect to the requirement that someone from the Defense Department or each agency shall be a member of the Board?

Dr. FURNAS. I am not sure whether it is provision of law, or regulation of the NACA itself. These are ex officio positions.

Whether they have set up that structure themselves, or whether it is a provision of law, I am not aware.

Mr. BROOKS. At any rate, the Defense Department is adequately represented at this time on the NACA Board?

Dr. FURNAS. I personally feel, although there are others who don't agree, that the Army should be represented if we are going to maintain our three military departments' organizational structure.

Mr. BROOKS. That is the only department which is not represented?

Dr. FURNAS. That is correct.

Mr. BROOKS. Because you do not know what is going to come out of this Pentagon reorganization, it may not be represented on there after that shakeup.

Dr. FURNAS. But I feel very strongly that, whatever may be the structure, the Military Establishment should be adequately represented on this Board, whatever it is called.

Mr. BROOKS. I share that view with you, because the military has given great impetus to the NACA program in the past, has it not?

Dr. FURNAS. Yes, sir; very much so.

Mr. BROOKS. How do they handle these projects when they approach a laboratory or university for the handling of a project? Can you give us very briefly how the NACA approaches that?

Dr. FURNAS. It is a matter of writing a contract. It may arise either way. It may be from the director of the staff that approaches the university because they know it has certain competence, or it may be that they know the university applies to the NACA and states, "We have an area in which we feel we are competent and we would like to explore and have your support."

It is a rather simple procedure. There is a definite contract that is written and handled with the director's office.

Mr. BROOKS. The contract is with the university or laboratory, not with the individual?

Dr. FURNAS. That is correct.

Mr. BROOKS. But the university obligates itself to provide scientific assistance which is needed to perform a project?

Dr. FURNAS. That is correct, and they usually will name the principal investigator they anticipate will be used.

Mr. BROOKS. NACA puts up the money?

Dr. FURNAS. That is right.

Mr. BROOKS. What sort of supervision, if any, does the NACA maintain over its project?

Dr. FURNAS. If the project goes along as it should, there is little supervision. There are reports that are required, of course. Usually there is a certain amount of personal contact, but there is only light supervision.

If they have confidence in the institution, then supervision is not really necessary.

Mr. BROOKS. There is nothing in the supervision at any time that would stultify the efforts of the scientists?

Dr. FURNAS. I have not observed any cases.

Mr. BROOKS. There is no part in NACA in any kind of supervision of contract to regiment scientists, is there?

Dr. FURNAS. I have never seen that in any NACA contract, sir.

Mr. BROOKS. Have you seen too much evidence there of a military concept, or military regulations or principles being visited on the colleges or the laboratories?

Dr. FURNAS. No, sir; I never observed any.

Mr. BROOKS. So your experience has been very satisfactory with it?

Dr. FURNAS. That is correct. Except I might add, sir, in general, they have not been willing to pay enough overhead to pay the full cost.

Mr. BROOKS. Well, I think you are a true American with that approach.

Do you think that that organization is named correctly? At the time I thought that the Advisory Committee for Aeronautics was not a very good name.

Dr. FURNAS. It is actually a misnomer. Of course, it arose as an advisory committee. That was the original concept, but then we very soon had to get into laboratory work so it became a very large operating organization in the research field.

So that the name of advisory committee is obsolete. But, then, it has the aura of age on it and it is well accepted. So I never felt it was necessary to change it just for that purpose.

Mr. BROOKS. Even though we would in this program add additional powers or functions to the NACA, you would not advise a change in the name?

Dr. FURNAS. Well, the NACA would disappear. It would be the National Aeronautics and Space Agency. I think that would be an appropriate title.

Mr. BROOKS. I want to ask you this:

In the new agency that is contemplated in this bill, H. R. 11946, this provides for a board of 17 individuals and only 1 representative of that 17 would be required to be from the military. The questions I am going to ask you are not technical, sir.

Your failure to have read the bill would make very little difference there. It is just general policy I want to get to.

Do you think that is ample representation for the military?

Dr. FURNAS. Before I could express a firm opinion, I would certainly need to study the bill.

Offhand I would say only 1 out of 17 from the Military Establishment would not be sufficient, but this is merely an off-the-cuff opinion.

Mr. BROOKS. My thought for sometime has been that in the initial establishment anyway, in the changeover, that there should be a minimum larger than one from the military if we are going to have a continuation program.

If, in this time, it is advisable to have only one from the military, then that should be posponed until a little later date.

Dr. FURNAS. I tend to agree with you, but this is not a well considered opinion because I have not had the time to study it.

Mr. BROOKS. You feel we should have a civilian agency, I am sure of that?

Dr. FURNAS. Yes.

Mr. BROOKS. I am sure we all are agreed on that. We are here and we are not going to get another chance perhaps to hear from you for a long time on this subject.

Are there any recommendations other than what you have made in your general statement that you would like to give this committee, which would assist us in pushing further and faster the program that we have under study here today?

Dr. FURNAS. I do not believe so, sir.

Mr. BROOKS (presiding). Thank you.

Mr. Hays?

Mr. HAYS. I have no questions.

Mr. BROOKS. Mr. Metcalf.

Mr. METCALF. Thank you, Mr. Chairman.

Dr. Furnas, when you were discussing with the chairman of the committee the need for power in the year 2000, you omitted falling water. That is a matter of a great deal of interest to the area from which I come.

Was it your idea that nuclear power would replace falling water, or that we would need all the power?

Dr. FURNAS. You will need the falling water and other things, too. Falling water, hydroelectric power, now supplies only about 1 percent of the total energy used in the United States.

If we developed all of it, it would still only supply a few percent, even at the present time. In 50 years it will just be a very small proportion, but we will continue to use falling water because it is convenient, should I say, and also the matter of dammed-up water is of importance in flood control, it therefore has at least a dual purpose.

So it is going to continue to be used. Where it is available close by it is inexpensive and it will probably continue to be so. So we will use it, but it will never solve the nuclear energy problem.

Nuclear energy will not replace it, but will be supplemental to it.

I should like to point out also that the use of electrical energy in the United States doubles in every 10 years. So if you carry that on for 50 years we have every reason to believe that the trend will continue, we will need 32 times as much power in 50 years as we have now, and we are going to have to use every available source of energy.

That is the reason nuclear energy is so important.

Mr. METCALF. I was sure that that is what you meant. In connection with other hearings in other committees we have had many educators before us who are talking about Federal aid to education.

The other day, the United States Chamber of Commerce said there were more than 81 different Federal-aid-to-education programs going.

That elicited a response from some of the educators that many of these were not Federal aid to education, but education's aid to the Federal Government.

I was interested that you had stated there was not enough overhead on such contracts.

Dr. FURNAS. That is right.

Mr. METCALF. Testimony has developed that many of these colleges are helping the Federal Government by carrying some or all of the overhead and thus paying some of the expenses of research out of their own funds.

Dr. FURNAS. That is correct. This might be repetitious—if you would not mind I would like to read, if I can find it, a portion of testimony I gave before one of the subcommittees of the House Government Operations Committee last year on this matter of overhead. This was in answer to a question.

Incidentally, this was a hearing on January 29, 1958, before a Subcommittee of the House Committee on Government Operations. Item 10, which was posed essentially as a question or for discussion:

> Any suggestions regarding actions Congress or the executive agencies can take to facilitate and stimulate scientific research and development in the United States and in the free world or to remove impediments thereto.

I said:

> Finally, I would like to speak of the support of university activities. As you well know, nearly all universities are in serious financial straits. It is also generally true that the more research a university does, the more serious its fiscal difficulties.
>
> In large measure this is due to the fact that, in practically no instances, do any of the Government agencies pay the full, that is, direct plus indirect costs, of research which is undertaken on Government grants or contracts.
>
> The losses on many projects, especially those supported by certain agencies of the Government, are often very severe. The more prosperous a university is in such research, the greater the loss.
>
> The inevitable result is that faculty salaries for both teaching and research have to be left at an unrealistically low level. To put it mildly, this has certain deleterious effects Because of low salaries, faculty morale tends to shrink to a low level. This is almost universal at the present time.
>
> Second, the better research men keep receiving tempting offers of higher salaries from Government agencies and from industry. Many of them accept such offers. This leads to a continual leeching away of the best talent and the weakening of the research accomplishments in the universities, which are the most important source of basic research, as well as of scientifically trained manpower. This definitely is not in the public interest and the situation should be remedied.
>
> I can illustrate the situation best by citing the current experience of the institution which I know best, and which I now head, the University of Buffalo. For the fiscal year 1957, the indirect costs—overhead—associated with research as established by our firm of public accountants in accordance with accepted accounting practice, was 81.17 percent of direct salaries.
>
> During the fiscal year 1957, this university carried on \$1,945,503 worth of research on contracts and grants. The direct salaries involved were \$1,046,505. Accordingly with the above-established percentage, we should have received \$859,913 for indirect costs. Actually, the total amount we did receive to cover these costs was only \$255,838.
>
> Thus the loss on research operations at my institution for this 1 year was \$604,075. Had this latter sum been made available, it would have been used largely for establishing more equitable salaries and would thus have greatly improved our research performance and potential. The total operating cost of my institution for both instructional and research work during this same fiscal year was \$6,114,055 Thus the amount of loss on the research contracts was 9.9

percent of the total budget. Such a percentage loss can well make the difference between making or breaking an institution, or between low and high performance.

In this instance, 34.8 percent of the research losses were from Federal Government contracts or grants. It is almost certain, because of the various national trends, that an increasing percentage of the research support in my own institution, will in the future, be coming from the Federal Government. So, the situation will become worse instead of better, unless remedial action is taken.

Mr. METCALF. If that condition continues it will mean that the that the college will have to discontinue this research service to the Federal Government?

Dr. FURNAS. It will certainly cut it down.

Mr. FORD. Will you yield?

Mr. METCALF. Certainly.

Mr. FORD. In the contract for research and development which the Department of Defense or the individual services make with universities or colleges and with private research organizations, do the private research organizations do any better in that regard than the universities or colleges do?

Dr. FURNAS. This depends on whether the private research organization can operate on the business-type contract, or whether they have to operate on the university-type of contract, however the organization is set up.

The military organization, particularly the Navy, which I think is better to negotiate with than the others, usually allow the bluebook formula, which is very much better than some of the other Government agencies, but I still think it does not adequately cover all of them.

In the case of my own institution the bluebook formula gives us an overhead of 65 percent plus.

Our public accountants say the overhead should be 82 percent.

In my own case the situation, which is worse, is that the National Institutes of Health by law is restricted at the present time to 15 percent of overhead which is completely inadequate.

This is my own situation. I do think the bluebook formula should be revised so that it gives more adequate consideration to the overhead for universities. All of the Government agencies should certainly go at least as far as the bluebook formula.

Mr. FORD. Who uses the bluebook?

Dr. FURNAS. The three military establishments.

Mr. FORD. Then the military seems to do better in this regard than other Government agencies.

Dr. FURNAS. That is correct, sir.

Mr. FORD. Is the bluebook formula acceptable to colleges and universities, or not?

Dr. FURNAS. In my case I feel it is not adequate.

Mr. FORD. Is the bluebook formula used with private research organizations?

Dr. FURNAS. If they are part of the university, yes. For instance, there are research foundations which are an integral part of the university and the bluebook formula is applied there.

Mr. FORD. It does not seem to me that it is fair that private research organizations should do any better than colleges or universities, but how do we get at that problem?

Dr. FURNAS. Pay all of them adequate overhead, sir.

Mr. FORD. When we make the money available we do not specify except in the HEW case, and that is by law.

Is it just a heritage which causes the problem or what is it?

Dr. FURNAS. I must say that I am not clear as to what can be done by legislation on this and how much of it is heritage.

I must also say that I think the universities themselves are at fault to a large degree because they have been willing to accept work at less than it cost them.

But you will never be able to get universities to have a unified front so I am afraid we are going to have to live with that.

Mr. FORD. Thank you very much.

Mr. METCALF. I thank the gentleman from Michigan for points which are of extreme interest to us.

Dr. Furnas, when you examine this legislation I hope you will be sure that this new agency we create does have the power under the law to adequately compensate the universities for these various very important research programs that have contributed so much not only to national defense, but to the entire domestic economy.

If you are not sure that there is adequate law to protect the universities, I hope you will suggest some language that will take care of that situation because time after time this question has been raised in recent months.

I believe it is one of the grave obstacles confronting us in developing future research and using our colleges and scientists for the betterment of our country.

Dr. FURNAS. I could not agree with you more, sir.

Mr. METCALF. Thank you.

Now, I think you developed rather completely the justification for the expense that this space program is going to cost. You showed and demonstrated by many instances that the result would be worth the expense.

You talk about another phase, how it was going to be organized. In your discussion with Mr. Brooks and with the chairman you used such language such as you felt the NACA had done very well and probably that was a good solution.

But "very well" is not enough. We want the best solution to achieve these results that you point out. I hope when you go over this legislation you will think not whether a 17-man board will do very well or a director will do very well, but whether that is the best kind of organization.

When you respond to the chairman's question, you will answer with that point in view?

Dr. FURNAS. Yes, sir.

Mr. METCALF. Thank you, Doctor.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. Doctor, several months ago one of the Members of Congress called upon a group of scientists to give their reasons as to just what was wrong with our missile and space research program. These gentlemen made certain observations, one of which was that at the present time science should have a place in the Cabinet and that it was important that this action take place as soon as possible.

How do you feel about that, Doctor?

Dr. FURNAS. My own opinion is that we should not have a cabinet post, a secretary of science, I think, would not serve any good purpose. I think it would add to the confusion.

Mr. NATCHER. Another observation that these gentlemen made was to the effect that a great portion of our material should be de-

classified. They felt that that would help us with our present research program. How do you feel about that?

Dr. FURNAS. I think there is a great deal of material which should be declassified. This can never be clean-cut. A good part of the reason for the lack of declassification is simply the great mass of material. Those who are responsible for the declassification are ordinarily not particularly interested and often are not in a position to spend the time and the effort to go through the great masses of material to see what should be declassified.

My own tendency is to be on the liberal side of declassifying, or not classifying in the first place, because every time you classify something you do hold up progress.

The question is: Are you declassifying ourselves or the possible enemy more?

We tend to overclassify and keep too many things classified. It is like legislating virtue. I do not know how you do it.

Mr. NATCHER. This group also made the suggestion, Doctor, that we should pool our scientific knowledge and skill with our allies today considerably more than we are doing. How do you feel about that?

Dr. FURNAS. Yes, sir; I believe that is correct. Western Europe is a great source of information and talent which I do not think we are adequately utilizing. This has its great difficulties, but I think we should pursue it more assiduously than we have thus far.

Mr. NATCHER. Doctor, I understand that you have not had a chance to read the bill. But there is one question I would like to ask you concerning the observations made by this group of scientists.

This bill, Doctor, provides that the Space Board should be composed of not exceeding 17 members. No more than 8 of the members of the Board are to be designated from appropriate departments or agencies of the Government, including at least 1 from the Department of Defense.

Members of the Board other than those appointed under the above section shall be eminent in science, engineering, technology, education, and so on.

Now, that is the present bill we have before us for study. It incorporates the President's proposal concerning this new space agency. This group of scientists, Doctor, in their opinion, felt that this new organization should be a commission composed of from 5 to 7 members; 3 or 4 of the members should be scientists; 1 from the military, 1 from industry, and that the chairman or the director should be a scientist well equipped from the standpoint of training and ability and also should have a fine administrative background.

Now, I realize, Dr. Furnas, that you have not had a chance to go through the bill and to make observations and arrive at your own opinion as to the bill. How do you feel about the suggestion that instead of having a director and a committee here of 17, that it should be a combination as outlined by this group of scientists? How do you feel about that, Doctor?

Dr. FURNAS. In my own opinion, and I must say this is based largely on the suggestion of NACA, is that this approach of the committee is the better one.

I also want to say that I certainly concur in the requirement for the director, that he be a scientist with high standing and administrative ability.

The reason I say a committee rather than a commission is a commission is necessarily going to be closely involved in the operating and probably the real reason for having a commission is when there are regulatory functions involved.

This is in the case of the AEC, there is a reason for having a commission there because there is a large body of regulatory element involved there, for safety and other things.

I do not believe there is the implication of this necessity for regulations in the space agency that is being discussed as there is in the case of the AEC.

Hence, I do not believe there is really as much of a justification for a commission. I would rather see it approached from the committee point of view and, of course, if this is not satisfactory, there can be later legislation if the commission function does seem to be desirable.

I, myself, cannot visualize that regulatory function, which is the real justification for a working commission.

Mr. NATCHER. Under this bill it provides for the director who is ot be appointed by the President and confirmed by the Senate.

In your opinion this director should be a well qualified administrator?

Dr. FURNAS. Without question.

Mr. NATCHER. And should be a scientist?

Dr. FURNAS. Yes, sir.

Mr. NATCHER. Thank you, Mr. Chairman.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. Dr. Furnas, I wish you would elaborate a little bit further with reference to your answers to the question by the gentleman from Kentucky in regard to making a Cabinet post of the Department of Science. You say it would add to the confusion

Why would it add to the confusion?

Dr. FURNAS. Because I think everybody which is added, in general, tends to add to the confusion. It is true that is a generalization.

Science so permeates everything that I don't see how you can pull everything together at one point and have a superman with his staff who will have all the right answers. I think it is analogous to the fact that everyone uses English language, presumably, in all Government activity, but I don't think anyone suggests there should be a Secretary of English as a Cabinet post.

I think the Secretary of Science is a little analogous.

Mr. NATCHER. You know we have a Department of Interior which has certain jobs to do. Do you anticipate that the time may ever come when we will need a Department of Outer Space?

Dr. FURNAS. I doubt it, but I suppose my crystal ball is very cloudy on that point. I do not think we should take that trouble on at the present time.

Mr. NATCHER. Now, you do not sound very optimistic as to our conquering and making extensive use out of outer space.

Dr. FURNAS. No, sir; I don't think we will make extensive use of outer space if you are speaking in terms of the number of people that will be there. It will be very few.

Mr. NATCHER. Assuming that we had no demand from a military standpoint, that the world was totally and completely at peace, and no one else was interested in space, would we be interested in space?

Dr. FURNAS. Yes, sir.

Mr. NATCHER. Why?

Dr. FURNAS. The acquisition of knowledge.

Mr. NATCHER. You would put it strictly on the basis of acquisition of knowledge; that is the curiosity of our scientific minds?

Dr. FURNAS. That is correct, sir. quite analogous to the study of astronomy in that way.

The basic motivation has been the acquisition of knowledge for astronomy. It has proved very useful just as all knowledge has proved useful, but the real basic motivation has been the acquisition of knowledge.

Mr. NATCHER. Now, has the basic motivation been the acquisition of knowledge?

Dr. FURNAS. I am speaking of astronomy now.

Mr. NATCHER. I am speaking of the achievements we have made in view of the fact that we have satellites orbiting the earth right now. What was the incentive in putting those in orbit? Was it curiosity of the scientific minds?

Dr. FURNAS. A large block, yes. This did not result in dollars, however.

Mr. NATCHER. They all go together, do they not?

Dr. FURNAS. Perhaps I did not state the point specifically enough, but the real justification for the effect and the money which is going to be put on exploration of space is first our military defense. We are not sure to what extent it will be useful, but we know it will be useful to a certain extent.

This is No. 1.

The second point is the knowledge which is gained will be useful to the human race. These are two motivating factors which are powerful and justify the expenditure of money in the eyes of the voters. This we have always to keep in mind, but in the basic motivation of the research scientists, to him it is always sufficient justification to go after something just in order to add to our fund of knowledge.

This is what distinguishes a fundamental research scientist. So there are three very important factors, but only on the first two can you get very much money. These are the practical aspects.

Mr. NATCHER. I certainly appreciate it. I think what we are faced with, Doctor, at the present time, is a political matter, and I am not speaking of the narrow partisan thing, but the overall situation. We are faced with being pretty realistic in this thing and I think that is the whole point of our being here this morning and discussing the possibility of a new agency.

That leads to the next question:

Do you feel we need a new agency, Doctor?

Dr. FURNAS. Yes, sir.

Mr. NATCHER. Why?

Dr. FURNAS. Because as it is now it is a matter of bits and pieces. Each of the individual services wants to set up its own space agency and I certainly agree that this should be a civilian agency.

I think it should be one that does not exist except insofar as it makes a very logical step to expand the function of NACA to do these things. NACA has been nibbling on the edge of this and it is the logical one to take this over.

Mr. NATCHER. What do you anticipate will happen to ARPA?

Dr. FURNAS. This is one of the things that puzzles me a little bit. I don't think any answer can be guessed at on that until we see what happens to the Department of Defense reorganization.

Mr. NATCHER. In other words, before we can, in my opinion, intelligently write a bill here and set up a new agency, I think we are going to have to determine whether or not ARPA shall be permitted to continue to exist or not.

How can we set up a new agency if that is going to be a confused point at issue?

Dr. FURNAS. I believe it should be the other way around. I believe the new agency should be set up and then the ARPA function adjusted within whatever happens in the Department of Defense to be adequately coordinated with the new agency, the NASA.

Mr. NATCHER. Would you anticipate authority in the new agency would be in a position to determine what happened to ARPA?

Mr. FURNAS. Not authority in the strict sense of the word, but I anticipate a well coordinate program. I do not think you can solve those problems of coordination and management by legislation. You can only provide the framework in which the direction is worked out properly.

Mr. NATCHER. Of course, that still goes back to the heart of the issue, it seems to me. You have made a very fine defense of NACA and I am not going to necessarily disagree with you.

Of course, I know there are people who disagree with you, but merely upgrading and changing the name of NACA is not going to accomplish the purpose, is it, Doctor?

Dr. FURNAS. If they are assigned the prime responsibility for the research in this area which we are calling exploration of outer space, yes.

Mr. NATCHER. All right. In what way is NACA limited by legislation or otherwise, today, in its authority and responsibility to move into this field? Are they restricted in any way in the field?

Dr. FURNAS. I think their assignment is the science of aeronautics. It does not include astronautics at the present time.

Mr. NATCHER. In other words, they have been bootlegging a little bit in getting in on some of these programs; is that not true, toying with something which you would say they did not have authority to get into?

Dr. FURNAS. I would express it, sir, that the fields have merged.

Mr. NATCHER. That is the point that the gentleman from New York has from time to time brought up, in other words, the degree or where the borderline comes between outer space or space as compared to what you might call aeronautics.

What is the scientific definition, Doctor, of the difference between aeronautics and astronautics? I think I know in general terms what Webster says about it. Aeronautics implies there is some air there.

In other words, aeronautics, strictly speaking, is confined to airborne vehicles and the physics of the atmosphere itself.

Astronautics is essentially those vehicles and devices which are out beyond where there is any perceptible atmosphere at all.

I might add that a ballistic missile, however, despite the fact that it does go through the atmosphere when it goes up and comes back through the atmosphere when it comes down is really an astronautical vehicle because it is following a ballistic course rather than something that is airborne.

The CHAIRMAN. In other words, it is difficult to bring about a straight line of divisibility.

Dr. FURNAS. Yes, sir; this is the reason I say the fields merge.

Mr. SISK. In view of the merger, that, of course, was my reason for asking you about any limitation on NACA. You say they have done an excellent job. I will not argue with you about that.

Let me ask you this: If their powers were broadened to include space or astronautics, do you think that would solve the situation and that we need no further agency or step at the present time?

Dr. FURNAS. Remember, sir, we are not creating a new agency; we are enlarging the assignment and responsibility and I think probably some of the authority of the NACA.

Mr. SISK. Now, I think we are getting down to the point. Is that what we are doing? That is not my opinion of what we are doing by any means.

Dr. FURNAS. Then I think I will have to study the bill first, sir, before I express an opinion.

Mr. SISK. Maybe that is what the authors of the bill had in mind. I do not know. Certainly it is not what I anticipate we had in mind.

But I feel that is what you feel is needed; is that right?

Mr. FURNAS. An expansion of the function and certainly the authority to a certain degree with the responsibility.

Mr. SISK. Doctor, to what extent do you feel we are utilizing at the present time our scientific and engineering know-how in this country?

Mr. FURNAS. Are you speaking of the efficiency with which we are utilizing them?

Mr. SISK. Yes. You know, of course, Doctor, of the great debate to some extent that is going on and has gone on for some time that we are falling behind in engineering know-how and engineering application and so forth, and that Russia is making great strides in this field, some of which I do not necessarily agree with, but I am concerned as to whether or not we are properly utilizing our scientific knowledge in making proper application of it.

I was curious as to whether you had any opinion about that, Doctor?

Dr. FURNAS. We are not nearly as inefficient as the severer critics indicate. However, we are a long way from perfection, I feel.

The real crying need is for a larger number of really top-flight scientists and engineers. We have a large number of mediocre, such as there are, of course, in any profession. The thing which is rather discouraging is the fact that we have not at the present time the prospect of having enough top-flight scientists and engineers 10, or 20 years from now.

Mr. SISK. Where do you think we stand with reference to Russia in that field, top-flight scientists?

Dr. FURNAS. I have no way of really knowing or judging the proportion of topflight ones that they have as compared to us. We do know they have some good ones. We do know they are producing more than we are at the present time.

Mr. SISK. More topflight people?

Dr. FURNAS. I have no way of grading them.

Mr. MCDONOUGH. Will the gentleman yield at that point?

Mr. SISK. I will be glad to yield.

Mr. McDonough. If we had more topflight engineers, physicists, and scientists today than we have, what more could we do than we are now doing? I am talking of astronautics and use of outer space.

Dr. Furnas. I think we would progress more rapidly. We would progress more rapidly at less cost.

Mr. McDonough. General Daley was here yesterday and I asked him if he was moving as fast as he could in the ballistic missile field. He said he could not go any faster than he is going right now.

Now, the question of topflight scientists and physicists in the exploration of outer space and the question related to it is whether we have as many such people as Russia. It has always posed the question in my mind whether we could go any faster if we had these people.

Dr. Furnas. You do not necessarily go any faster by putting more engineers on the design board.

Mr. McDonough. Then Russia cannot move any faster than we are because they have more scientists if that is true.

Dr. Furnas. If you have really intelligent and very competent scientists and topflight engineers in the initial planning stage, you make fewer mistakes. In all of these experimental things you have more mistakes than you have successes.

So your speed depends very greatly on your ratio of right theory or rightness, if you want to call it that, as against the number of mistakes.

So the more really topflight, very intelligent, and very capable people you have, the fewer mistakes you make and the more rapid your progress.

Mr. McDonough. That stimulates another question in my mind.

Do you think at the present time Russia has advanced scientific knowledge on astronautics that we do not have?

Dr. Furnas. I doubt, sir, if they have knowledge that we do not have. They might have, but I don't have reason to believe they do.

Mr. McDonough. They are operating under the same basic research and attempting to implement the natural laws the same as we are, so far as astronautics are concerned?

Dr. Furnas. Yes, sir; the law of physics are the same in Russia as they are here.

Mr. Sisk. I have one concluding question, Doctor, and then I will yield the floor.

What amount of urgency, then, do you place on this program? Do you feel we have become unduly alarmed with reference to trying to expedite our conquest of space and our utilization of it?

Dr. Furnas. No, sir; I do not think we have become unduly alarmed because this is a race from the military and national defense point of view and there is nothing more difficult than to catch up in a race after you have slipped behind a little bit.

It is certainly very important that we proceed as expeditiously as possible, but avoid being frantic. If you become frantic, you soon wear yourselves out and you make less progress, but I think we should take this very seriously and expedite it with all dispatch.

Mr. Sisk. It is not actually true when you analyze it that the vehicles, the hardware that has been developed, the actual research and so forth that has put us at least in a limited way into space and that we have been able to launch satellites, are strictly programs developed by the military and that no civilian agency in a sense has contributed a great deal, NACA or anyone else?

Now, I think that should have some consideration in the type of agency we might set up to expedite the program.

Dr. FURNAS. I think it is not correct to say that other agencies have not contributed.

Mr. SISK. I did not mean to say they had contributed nothing, but I am speaking of the great majority of contributions.

Dr. FURNAS. As far as the bulk of the hardware, yes; it has been the military, namely the rockets and control systems.

The National Science Foundation in the International Geophysical Year, has been very significant. Also the volunteer people you might say in the national committee headed by Dr. Kaplan, for the International Geophysical Year have contributed a great deal to the scientific theory, to the instrumentation, and are contributing tremendously to the interpretation of results.

So that I think their contribution has been very significant and will continue to be so.

As far as the tons of hardware, which is primarily the propulsion system, this has been the military, that is correct.

Mr. SISK. That is all, Mr. Chairman.

The CHAIRMAN. Mr. McDonough.

Mr. McDONOUGH. Doctor, you mentioned the new sources of potential power in outer space. If there are quantities of oxygen that could be used to propel a vehicle in outer space, how are we going to collect it and use it practically?

Dr. FURNAS. Sir, you will have to go up there to use it.

Mr. McDONOUGH. Yes, of course.

Dr. FURNAS. This is a layer which is roughly 60 miles above the surface of the earth.

Mr. McDONOUGH. Nascent oxygen; is that close?

Dr. FURNAS. That is right. Apparently this is one of the things we don't know. Apparently 50 percent of the oxygen molecules are in that condition.

Perhaps it will be useful to have a vehicle circumnavigating 60 miles above the earth for a reconnaissance vehicle.

If it does work out, they will have a perpetual energy supply there. I don't know if it will be useful for civilian travel, but the thing that intrigues me most is the fact that we can study that material there and learn how to use it, and it is going to help us to learn more about the use of some free radicals.

Oxygen is not the only thing that can be treated this way. We are going along with the Bureau of Standards on research on free radicals at this time. I think the knowledge we can get 60 miles up will be useful.

Perhaps that layer of fuel up there will be useful to military or civilians. I don't know.

We do need to find out.

Mr. McDONOUGH. In other words, to get to that position, you would use another type of fuel and after you get there you would have to have an engine designed to use the free oxygen in the air.

Dr. FURNAS. Yes.

Mr. McDONOUGH. Would that be an explosive propelling force?

Dr. FURNAS. No, it would be a ram jet with continuous thrust. You would squeeze the molecules together and just by the fact that

you bring them close together they would recombine and produce energy.

You may have heard of the atomic hydrogen welding torch which was developed years ago by the General Electric Co. in which they take hydrogen and pass it through an electric arc and break up the hydrogen molecules into the two atoms.

When they recombine with oxygen they produce hotter flame than the hydrogen-oxygen flame.

What we are talking about is quite the same reaction.

Mr. McDonough. That would remove the danger of radiation in a nuclear powered ship, would it not?

Dr. Furnas. Yes, sir.

I might point out that the source of energy in this case is solar energy, the energy from the sun's rays.

Mr. McDonough. Do we know that there is a consistent quantity of that at a 60-mile height?

Dr. Furnas. This I am sure is one of the gaps in the data. Perhaps Dr DuBridge will know more on that than I do.

Samplings from the rockets that have gone up have indicated that there is a consistent layer there. I think that some of the future satellites that we send up may get some more information on that, although it will be too close to the earth for the satellite orbit.

As they go up and as they come down we may be able to get some more information on this.

Mr. McDonough. The energy source will be the combination of molecules; is that right?

Dr. Furnas. That is right.

Mr. McDonough. That is the heat of association?

Mr. Furnas. That is correct.

Mr. McDonough. As distinguished from the heat of disassociation in the nuclear bomb; is there such a thing?

Dr. Furnas. You could hardly speak of it as disassociation in a bomb. That is a different reaction.

Mr. McDonough. What do you think of establishing an extensive course of astronautics at the Air Academy at Colorado Springs?

Dr. Furnas. You mean as part of the undergraduate work?

Mr. McDonough. Yes.

Dr. Furnas. I presume this will be one of the things which will be forthcoming. It is a natural course of events if we are going to use astronautical vehicles.

Mr. McDonough. You mean that there is a correlation between aerodynamic and astronautics that should be associated with the study of these things?

Dr. Furnas. Particularly in the matter of training at the undergraduate level; yes, sir.

Mr. McDonough. We always have a problem, such as we attempted the other day, on the reentry of a cone shot in outer space and coming back to earth. Why is there not the same problem of the cone entering outer space with the power behind it as there is in reentering space?

Dr. Furnas. Because you go slowly as you go up.

Mr. McDonough. You mean you come back faster?

Dr. Furnas. Yes, very much faster.

The Chairman. Mr. Fulton.

Mr. FULTON. Glad to have you here, Dr. Furnas.

Dr. FURNAS. Thank you.

Mr. FULTON. I was interested in your discussion with the gentleman from California on the ionization of oxygen. Has that layer ever caught fire due to any of these rockets?

I think I read some place where some had caught fire a little bit; is that right?

Dr. FURNAS. I only know of one experiment, and I have forgotten just what was ejected, but they did eject, I guess it was sodium at very high velocity at that altitude and this really served as a catalyst for this recombination of the oxygen molecules and there was, shall I say, a quite brilliant light in the area which gave evidence of the recombination if you had the proper material up there.

Mr. FULTON. So if somebody wanted to destroy the world, they could put the proper catalyst up there and this whole circle of oxygen would be ionized and combined?

Dr. FURNAS. The effect would be quite limited. It is not something you can trigger and have the world entirely circled with fire. I do not think we need to feel uncomfortable on that.

Mr. FULTON. With respect to the ionization we are speaking of, their breaking O_2 down to 2O, could that be used in conjunction with ordinary ion propulsion that he speaks of?

Dr. FURNAS. I personally do not see offhand how we could. But I am not sufficiently experienced in that field to give a definite answer to that.

Mr. FULTON. So the use of this ionized oxygen would really be limited to this band above 60 miles above the earth?

Dr. FURNAS. Yes.

Mr. FULTON. And the space vehicle or the engine would have to really be confined to that area in case we were going to have the propellent taken from the atmosphere.

Dr. FURNAS. That is correct, sir.

Mr. FULTON. Have there been any experiments on the ionizing of oxygen for some vehicles regardless of this particular layer that we are speaking of?

Dr. FURNAS. Roughly analagous, this is the free radical research I spoke of.

Of course, many substances that you can break up in the ionized forms, tend to, of course, at the ordinary pressures and temperatures, recombine very rapidly. I spoke of the hydrogen torch which is used. They recombine in a matter of a few thousandths of a second.

However, when you take them down to a very low temperature, you can keep them in this free radical form. This is essentially the approach that is being made now to see whether or not you can store up greater concentrations of energy by taking a substance, which is ordinarily a fuel anyway, and then giving it this extra storage of of energy by dividing it into ionized form and holding it that way until you want to recombine again.

We do not know this will work, but there is the possibility. We are quite sure that it can work as far as the laws of chemistry are concerned, but whether or not you can have a practical device that can handle it, we do not know.

It is very touchy material because when it does start to recombine it does so with great violence.

Mr. FULTON. The point I was making is, would it be worthwhile to have a program of research on this in order to reduce the size, the bulk as well as the weight, for example, of the Vanguard in the first and second stages?

Dr. FURNAS. There is a program of research on this sort of thing. I think it should be increased and emphasized more.

Mr. FULTON. How much more money do you think should be spent on such a program?

Dr. FURNAS. I would have to go into a detailed study of the program.

Mr. FULTON. You can place that in the record.

Another point I would like to make is this: You have spoken of the fact that we should not probably look at outer space in the context of freedom of the seas; is that right?

Dr. FURNAS. I said that I did not feel that the outer space was not an analogous case to the freedom of the seas.

Mr. FULTON. On what basis should the United States set its policy? Should we have a national space policy as distinguished from a United Nations policy?

Dr. FURNAS. I am afraid you are getting beyond my depth or my reach; I am not sure which.

Mr. FULTON. You would favor a national space policy for the United States, would you not?

Dr. FURNAS. If you can set up a practical policy, yes, but I am puzzled as to what would be involved in this policy.

Mr. FULTON. Would you try to get an international conference? I have suggested that several times, a meeting of all the nations to try to set up some sort of agreement or treaty that would control outer space and its development.

Dr. FURNAS. I must say, sir, at the present time I do not see how we can physically control outer space. So I think any such treaty would be meaningless.

Mr. FULTON. Grotius had the idea of freedom of the seas and then John Selden of England came up in 1655 with the dominion of the seas.

Do you think the United States should try for dominion of outer space as distinguished from leaving it as a free space and we do what we wanted?

Dr. FURNAS. I think for the moment we should leave it as free space to do what we wanted, because I do not think we have enough wisdom to devise a policy which will mean anything.

Mr. FULTON. So you would not go into outer space as a United States policy, but primarily as a military or dominion procedure?

Dr. FURNAS. I think our primary reason for going into outer space at the present time is military; yes.

Mr. FULTON. Should we race with Russia for the control of outer space, then?

Dr. FURNAS. I think it is highly important that we get vehicles there which will be useful for military reconnaissance. This is the outstanding aspect.

Mr. FULTON. So that you feel it is necessary to have a national space exploration policy for our own security?

Dr. FURNAS. That is correct, sir.

Mr. FULTON. May I finish with this. I believe that you had some contact with the decoding of the signals of the sputnik, did you not?

Dr. FURNAS. No direct contact; no.

Mr. FULTON. Do you, of your own knowledge, know what the results of these decoding operations have been if it is not classified material?

The CHAIRMAN. I might say that any question asked that goes into classified areas, you gentleman just simply say so.

Dr. FURNAS. All that I have learned on this has been with conversation with others that have been more involved in this and they say they have gotten so far very little information from the Russian signals, from their instrumentation. Apparently the Russians have published a little bit, but not very much. They have promised to publish more.

The information so far gathered from the Russians has been fragmentary.

Mr. FULTON. Thank you very much.

The CHAIRMAN. Mr. Keating.

Mr. KEATING. Dr. Furnas, do you look upon the control of so-called outer space as well nigh an impossibility?

Dr. FURNAS. Yes, sir.

Mr. KEATING. Because of the vastness of the area?

Dr. FURNAS. That is correct.

Mr. KEATING. Do you look upon outer space as different in kind from the atmosphere immediately above the earth or just an extension of the atmosphere.

Dr. FURNAS. It is different in kind in the sense there is no atmosphere there, but primarily because of the vastness of space.

Mr. KEATING. It also has entirely different physical properties?

Dr. FURNAS. That is correct.

Mr. KEATING. There are differing views. We have had a good many Defense Department witnesses and some have said that the difference between the earth's atmosphere and outer space was like the sea with different areas of density.

Others have felt that there was a more vital difference, as I would put it, the difference between land and sea.

Which do you think is more accurate, or is it in between?

Dr. FURNAS. I would vote for the more vital difference, sir.

Mr. KEATING. That was my impression.

In your answer to the gentleman from California that there should be a course of astronautics in the Air Academy, you did not mean to exclude West Point and Annapolis in that?

Dr. FURNAS. No, sir.

Mr. KEATING. In other words, this is a matter that undoubtedly engages the attention of the young men in all of our service academies?

Dr. FURNAS. I think so; yes, sir.

Mr. KEATING. And the University of Buffalo?

Dr. FURNAS. Yes, sir.

Mr. KEATING. Now, you are of the school of thought, I believe, and we have conflicting testimony on this, you are of the school of thought that this new Agency should not be limited simply to research.

Dr. FURNAS. Here, sir, you get into the definition of research. I think the scope should be research and whatever is necessary in order to prove the feasibility of vehicles or devices.

In other words, I do not think it should be confined purely to fundamental research. I think the pattern which the NACA has worked

out, of the degree of development they have gone through, has been quite satisfactory for their aeronautical field.

Mr. KEATING. The functions of the agency include the development, testing, launching, operation of aeronautical and space vehicles. In another area they are given the authority to acquire, construct, improve, repair, operate and maintain laboratories, research and testing sites and facilities, manned and unmanned aeronautical and space vehicles, and so forth?

Dr. FURNAS. Yes.

Mr. KEATING. Now, this is a very broad operational authority, would you not say, sir?

Dr. FURNAS. Yes, but it is necessary to carry on this research in space. You are simply hobbling horses if you are saying you can only take steps so large. The distinctive point is that they shall not go into the manufacture. In other words, they shall not do production and development, but it is only for their exploration activities they need to develop the vehicles that have not been developed before.

Mr. KEATING. Yes, I understand your point. You think they should have authority?

Dr. FURNAS. They should; yes, sir.

The CHAIRMAN. Of course you recognize that the bill calls for not less than one member of the Defense Department, it could be more. Of course that is a matter of the discretion of the President. He could appoint more than one member.

Dr. FURNAS. Yes, sir; but I do believe one is too small a minimum to be specified.

The CHAIRMAN. You do have sufficient confidence in the President of the United States to know that he would use his judgment.

Dr. FURNAS. The present President, yes, sir.

The CHAIRMAN. Well, I said the President of the United States.

Mr. KEATING He thought, though, Mr. Chairman, that the minimum that we put in the legislation should be something above one.

The CHAIRMAN. I am not expressing any views, I am just exploring.

Mr. KEATING. I was not sure that you got his thinking.

The CHAIRMAN. I think it is well to explore with the witness to get their views.

My mind is completely open. I have some fixed views but I will discuss them in executive session.

Mr. Ford?

Mr. FORD. Dr. Furnas, from your experience as Assistant Secretary of Defense for Research and Development, do you think it is wise or unwise in the appointment of individuals from the Department of Defense that there should be one from each service?

Dr. FURNAS. With the present setup of the Department of Defense yes, sir, because this is the only way you can get appropriate representation of the different military disciplines if you choose. Whether this will be wise after the legislation on the reorganization of the Department of Defense I could not express any opinion.

It depends on how that turns out. I think it is essential that there is representation of the major activities, and if those major activities are separate and autonomous, you have to have those representatives there.

Mr. FORD. I am not entirely familiar with the details of the proposed change in the research and development aspects of the Depart-

ment of Defense but I gather from what I have read that it would give a greater degree of control in the Assistant Secretary's Office, more, for example, that what you had when you had their responsibility?

Dr. FURNAS. Yes, sir.

Mr. FORD. As a sideline to this legislation do you concur in that new approach to that problem?

Dr. FURNAS. Yes, sir.

Mr. FORD. It would have made your job much easier and more effective?

Dr. FURNAS. I do not know it would have made it easier, it would have made it more effective.

Mr. FORD. If that proposal goes through, that aspect of the reorganization, then you would see less necessity for equal representation from each of the three military services in this legislation?

Dr. FURNAS. That is correct.

Mr. FORD. As I look at section 6 (b) (5), the pertinent portion is on page 8, it seems to me that the legislation, as drafted now, would seem to take care of the problem raised by the gentleman from Montana, Mr. Metcalf. I would like to read it and see if you concur.

It says,

> In performance of the above functions the Agency is authorized without regard to section 3648 of the Revised Statutes, as amended, to enter into and perform such contracts, leases, cooperative agreements, or other transactions as may be necessary in the conduct of its work and on such terms as it may deem appropriate, with any agency or instrumentality of the United States, or with any State, Territory, or possession, or with any political subdivision thereof, or with any person, firm, association, corporation, or educational institution.

That would seem to give a very wide discretion, a high degree of flexibility in entering into contracts and so forth.

Dr. FURNAS. My first reaction is that this seems to be sufficiently all-inclusive. I would really want to study it a little bit more before expressing a firm opinion.

Mr. FORD. It would seem to put vast authority in the hands of the Director in reality for the entering into such agreements. So here it seems to be the good will of the Director in making the kind of contract with educational institutions that would be satisfactory to them under the appropriate criteria to be developed.

Dr. FURNAS. That is true. Of course, the other factor that enters into this is the Bureau of the Budget which overrides many things in contractual regulations.

Mr. FORD. I gather then that you feel from your own practical experience that even legislation of this sort, if it is not buttressed a bit, could be hamstrung by administrative interpretations by the Bureau of the Budget?

Dr. FURNAS. That is correct. I am not sure how far legislation can go in the matter of compensation, of full compensation for work done.

Certainly speaking from the background of lack of knowledge as to what can be effective legislation, it seems to me there could be language that would make it imperative that full recognition be given to full cost in these contractual regulations. I am reading this because there are regulations now in the National Institutes of Health which prevents paying full cost. So I presume it would be necessary to require legislation that would require full cost.

Mr. FORD. In your contacts with various Government agencies where you are trying to negotiate research contracts do you find that those who represent those agencies do seek to give you adequate compensation but then they say, well, we have the Bureau of the Budget to contend with?

Dr. FURNAS. Not in all cases; no, sir.

Mr. FORD. In other words, even some of these agencies themselves or the people representing them are at fault in this problem?

Dr. FURNAS. The administration, yes, within the agencies themselves They tend to haggle. They look upon it that I have so many dollars and I want to get the most research I can out of them and if you are willing to take it at a loss, why this is what we are going to do.

Mr. FORD. If you don't we will get somebody else?

Dr. FURNAS. That is correct, and they often do.

Mr. FORD. I think it is a very serious problem. I think the committee ought to do what it can to be helpful. I am glad to hear that your experience indicates that the Department of Defense at least seems to be more realistic than some of the other agencies.

Dr. FURNAS. They are more realistic, yes, sir.

The CHAIRMAN. Mr. Feldman?

Mr. FELDMAN. Doctor, in response to a question from Congressman Keating regarding the NACA setup you said that the essential character of the Board and its functions should remain the same.

The Board, when you served on it, was the top ruling agency in the NACA; is that not so?

Dr. FURNAS. Yes, sir.

Mr. FELDMAN. You set the policy and the Director carried it out; is that correct?

Dr. FURNAS. That is correct, sir.

Mr. FELDMAN. And you had the right to discharge or change the Director if you so saw fit or at least make a strong recommendation that he be changed?

Dr. FURNAS. I could make a recommendation; yes, sir.

Mr. FELDMAN. In other words, the Board was the top authority in the Agency. Is that not true?

Dr. FURNAS. Yes, sir.

Mr. FELDMAN. Under the new proposal the only function of the Board is to recommend and advise. You can accept that, Doctor, because there is no provision in the law which says their recommendation has to be followed by the Director. In other words, the setup is changed so that under the new proposal the Director would be the top authority and the Board would have no power other than to recommend and the Director would not be obligated in anyway under this new proposal to accept that recommendation. That is the fact within the law. I do not think there is any dispute about that. I mean the new proposal.

Mr. KEATING. Would the gentleman yield to me?

Mr. FELDMAN. Yes; I will.

Mr. KEATING. I think probably the legal conclusion is right, but I am wondering if that does differ from the setup of the present NACA or whether what Dr. Furnas was talking about was the way it operated in practice rather than the legal way it was set up.

Dr. FURNAS. I am not familiar sir with the language of the act on NACA but I was under the impression that its role was advisory, that

it was in effect controlling because the Director did follow the consideration of the Board in determination of policy.

The CHAIRMAN. We can settle that very quickly. Here's a chart given to us by Dr. Dryden. The National Advisory Committee for Aeronautics is at the top and the NACA Headquarters, Washington, D. C., and the staff is under the 17-man Board.

So, organizationally, in the law the National Advisory Committee for Aeronautics could be and was the top operating unit. Now whether in fact it was or not is a difficult question.

Mr. KEATING. Mr. Chairman, I would anticipate that Dr. Dryden, if he were givin us a chart of this new Agency would set it up exactly the same even with the wording that we have in this bill.

The CHAIRMAN. He testified to the contrary, that he would be the top man.

Mr. FELDMAN. He not only said that but under the new setup he characterized the Advisory Board as "kibitzers."

The record is clear on that.

Mr. KEATING. My opinion is this, Mr. Chairman. I do not think you can look at a chart to determine what the present setup is. I do not know, I have not looked at the law, but I think we have to look at the law setting up the NACA and see by looking at that whether it differs from this law in that respect. Perhaps counsel has done that.

Mr. FELDMAN. I have and it does differ in that respect.

Mr. SISK. Would the gentleman yield there?

Mr. FELDMAN. Yes.

Mr. SISK. To clarify the answer to your question a moment ago, did you accept the thesis as propounded that when you were a member of NACA that it operated in the other direction—as a practical matter now—that is, that the Board controlled what the Director did, what Dr. Dryden did?

Dr. FURNAS. It seemed to me the action of the Board was essentially analogous to the board of directors of a corporation and it operated in that way.

You did not give detailed instructions but you set the general pattern and the policy, and you discussed major activity and the Director sought the guidance of the Board. Whether this was by tradition or by law I am not sure but I know they did operate as really the top governing body.

Mr. FELDMAN. In fact I used that very illustration to point out that the NACA function of the Board is in the nature of a board of directors but under the new setup where the Director is on top and the Board is purely advisory. Because the proposed Board only has the power to recommend, then we lose that identity of the Board remaining a board of directors. What are your views regarding this change?

Dr. FURNAS. I would say as a practical matter to me it is obvious that whatever legislation was set up for NACA has worked satisfactorily. I feel that the same language should serve for this new Agency.

The CHAIRMAN. On the question of responsibility do you think you would get more direct responsibility from a 17-man Board operating than 1 man? A 17-man Board can do it if they want to. They have complete authority. If they did not do it that is their fault?

Dr. FURNAS. The effectiveness of a 17-man Board will depend on how judiciously they use their authority. If they begin using this authority in every minute detail it simply won't work.

The CHAIRMAN. Under the original act they could if they wanted to.

Dr. FURNAS. They could; yes.

Mr. FELDMAN. It is like cooperating with a board of directors. The board of directors wants to set the policy.

It gives the orders to the president and the president is supposed to carry out those orders. The test is usually what the figures are at the bottom of the line at any given period to see how effectively he is carrying out those instructions.

Mr. FULTON. Would the gentleman yield on that point?

Mr. FELDMAN. Yes.

Mr. FULTON. Do you feel that giving the National Space Agency a tremendously expanded field would call for full-time people rather than part-time advisory committee members who meet possibly 4 or 6 times a year, and do the job as a side issue?

Dr. FURNAS. I feel, and this again is partly because of the success of the other pattern, that this Board meeting occasionally is the better way to do it. If you are going to have it full time, this comes over to the Commission structure, which I feel is necessary when you have a regulatory function.

But, if you have this Commission structure which is full time, then they will begin to get into operating details, and I don't think this is the best way to run a research and development organization.

Mr. FULTON. With a commission structure, we could set up by legislation that they have an advisory consulting board, just as many other Government agencies do at the present time; could we not?

Dr. FURNAS. It is possible. The advisory boards are useful but they are not as effective as the NACA. I feel that the NACA structure, with certain well-defined responsibilities—and actually meeting directly four times a year is too few. I do not feel that is an appropriate way to do it.

Mr. FULTON. That is all.

Mr. FELDMAN. In response to Congressman Fulton's question you stated the agency has regulatory functions. Would not this new agency have regulatory functions?

Dr. FURNAS. I do not think it would have.

The CHAIRMAN. What about licenses?

Mr. FELDMAN. Would they be any less regulatory than the Atomic Energy Commission?

Dr. FURNAS. Yes.

Mr. FELDMAN. You talked before of the fact they have the safety problem in the Atomic Energy Commission.

Dr. FURNAS. That is correct.

Mr. FELDMAN. Do you envision the fact that there may be great safety factors involved in connection with the launching of missiles?

Dr. FURNAS. This will be part of the military function as I see it. It may be part of the Weather Bureau sometime or it may be part of the National Science Foundation.

Mr. FELDMAN. If this expanded organization is to go into the development of new missiles or new satellites or new vehicles that will go into outer space, will they not involve grave danger factors?

Dr. FURNAS. Not grave danger factors; no, sir.

Mr. FELDMAN. They could involve because of the use of these exotic fuels and things of that sort. Won't they have to regulate?

Dr. FURNAS. I don't visualize they will have to regulate except for their own internal regulation.

Mr. FELDMAN. There will not be any concern if you establish a new site in the interior of the United States or any place in the United States, you won't have to have regulations?

Dr. FURNAS. Not in the sense that the AEC has to have regulations on the safety of the use of fissionable materials, no, sir.

Mr. FELDMAN. These exotic fuels are pretty dangerous and have to be used properly and you have to have regulations concerning them, do you not?

Dr. FURNAS. As far as the launching sites are concerned, yes, sir.

Mr. FELDMAN. And there may be a lot of launching sites. We are talking about, for example, a million-pound thrust engine, the launching of a satellite from an engine of that kind which might certainly be one involving health and safety?

Dr. FURNAS. Not to the extent of the hazards of fissionable material.

Mr. FELDMAN. Well, the danger may not be as great but it still requires some regulations, is that not so?

Dr. FURNAS. Not in the national sense, no, sir, I don't think it does.

Mr. SISK. Would the gentleman yield again?

Mr. FELDMAN. Yes, sir.

Mr. SISK. We had testimony before this committee about the danger of dirtying up space with too many satellites. Very frankly this was proposed as I recall in good faith, that it might need some regulations. I am curious to know if you have any comment as to the regulations concerning that feature?

Dr. FURNAS. I certainly cannot get frightened with having too many satellites up there, there is an awful lot of space.

Mr. FELDMAN. Would it control who goes up in outer space? Would you let anybody go up?

Dr. FURNAS. I don't see any reason to prevent them at the present time.

Mr. FELDMAN. Won't there be some traffic problems?

Dr. FURNAS. No, sir.

Mr. FELDMAN. Never?

Dr. FURNAS. I do not visualize it, no.

Mr. FELDMAN. Aren't we in the same relative position as we were at the time of the development of the airplane when we did not have the need for traffic problem?

Dr. FURNAS. The NACA has done a very effective job in the research end, but they have not done anything in the regulatory end. If we are going to have regulations of the Space Agency it should not be NASA.

Mr. FELDMAN. What about communications? We are giving them this expanded authority where they can go into all these fields.

Dr. FURNAS. If you are talking of allocation of wavelengths this is the job of FCC and they have to use certain bands.

Mr. FELDMAN. Won't they have to come to this new Agency?

Dr. FURNAS. No, the FCC will regulate the allocation of bands.

Mr. FELDMAN. In outer space?

Dr. FURNAS. Yes, because the radiation is coming in from outer space. It is simply a matter of interference with communication. In general, I would hate to see this new Agency get into the regulatory business.

The CHAIRMAN. Doctor, I can appreciate your answer to the immediate situation but we have to project our minds ahead and see what the law of natural consequences probably might be.

Dr. FURNAS. I think there will be plenty of time, sir, for additional legislation if that is required.

The CHAIRMAN. I take it then from your testimony you do not think much of this new Agency, do you?

Dr. FURNAS. Yes, I think a great deal of this new Agency.

The CHAIRMAN. In other words, you think 10 or 15 or 20 years from now after the military has done its operating, then what flows from the military activities to be used for peaceful purposes might be then drifted over to the civilian side of the Government. I would take it that is the substance of your mind?

Dr. FURNAS. No, sir. In the foreseeable future I don't see any lessening of the necessity of the military development.

The CHAIRMAN. I agree with you on that. When I analyze what you say I am wondering what is left of this new Agency.

Dr. FURNAS. All of space.

The CHAIRMAN. I know but the military has taken all of that now.

Dr. FURNAS. No, sir. This is to do the essential background research and development for this and the military applications. Specific military application will be the role of the military.

The CHAIRMAN. I know, but the role of the military today could almost be 100 percent, could it not? What is left of this new Agency is what I would like to know?

Dr. FURNAS. There has been a tremendous amount and there is still a tremendous amount in conventional aeronautics if we might use the term, at the present time for NACA and it has been the backbone of a great deal of military developments in aircraft and in missiles too.

The CHAIRMAN. That is upon permission of the military, when they ask them to come in and cooperate with them, is that right?

Dr. FURNAS. That is correct.

The CHAIRMAN. Of course, the NACA cannot get into the military research unless they ask the NACA, or the new Agency, to do so. I am wondering what original jurisdiction this new Agency will have once it is established?

Dr. FURNAS. It will have the jurisdiction of the background research and development in the exploration of space.

The CHAIRMAN. But the military, according to your testimony, is primarily interested in that and the biggest part of that is going to be connected today, tomorrow, and in the foreseeable years with the military. I am not arguing against that now. I am trying to project my mind and analyze what is left of this Agency as a matter of original jurisdiction.

Dr. FURNAS. I think it is a matter of the original jurisdiction, very much the same as it has been in aeronautics since 1915.

With respect to my statement on the role of the military, I felt that if there are areas of background and fundamental research which are probably going to be of interest to the military and it will not be

covered, then the military should undertake that itself. But I anticipate that the Agency will plug the holes quite well if given proper support.

The CHAIRMAN. What holes will be left as a matter of original jurisdiction?

Dr. FURNAS. This Agency will be the one which will have that original jurisdiction.

Mr. McDONOUGH. Along that thought, do I understand you to mean, Doctor, that this Agency will be the agency for basic research and development in astronautics and will not be an operational agency?

Dr. FURNAS. No, sir; it will not be an operational agency.

Mr. McDONOUGH. It will not be?

Dr. FURNAS. It will not be.

Mr. McDONOUGH. It is strictly a research and development agency?

Dr. FURNAS. That is right.

Mr. McDONOUGH. For the purpose of coordinating the men, physicists, and scientists who are devoted to that under its jurisdiction?

Dr. FURNAS. Yes, sir.

Mr. McDONOUGH. Both in the civilian pursuits and in military expansion.

Dr. FURNAS. They will not have any authority over the military. They certainly will deal in subjects which are of interest to the military.

The CHAIRMAN. Who would be the operating agency if we can ever get into this peaceful side? Who will be the operating agency?

Dr. FURNAS. For the military?

The CHAIRMAN. I a m excluding the military now. Who will be the operating agency? You say it is confined to research and development. There will be something beyond that sometime, will there not?

Dr. FURNAS. I anticipate that there may be some Weather Bureau activities at sometime just as the Weather Bureau operates weather ballons. Whether this will be used as transport or not I do not know. If it does come to commercial transport it will come under the CAB and CAA.

Mr. KEATING. May I ask a question on that point? Dr. Furnas, under the wording of this bill, whether it is right or not, I think it is operational because we are giving them the authority to acquire, construct, improve, repair, operate, and maintain laboratories, research and testing sites and facilities, manned and unmanned aeronautical and space vehicles. This agency is given by this bill authority to operate a fleet of space vehicles. Whether we want to do that or not is another question, but under the wording of this, in my judgment, that language is not capable of any other interpretation.

Dr. FURNAS. Perhaps I am getting the wrong slant on the semantics of operation here. The necessary operation to carry out a research and development program, yes. But operation as military weapons, no. Operations for commercial transport, no. Operation as a function of the Weather Bureau for long-range weather predictions, no.

Mr. KEATING. But I think if we are going to negative that authority, we would have to add something to this language because this is in a separate section from the one talking about development.

This is the broad authority to operate the McCormack Space Vehicle Corporation to the stars, and I do not think you can limit the language unless you put some more in there.

Dr. FURNAS. Perhaps, sir, if you put in a phrase, the language there for research and development purposes.

The CHAIRMAN. Mr. Fulton has a question he wants to ask. Mr. Fulton.

Mr. FULTON. Who in your theory would launch a space vehicle for peaceful purposes, whether for an exploration of space experiment or testing the type of vehicle?

Dr. FURNAS. Certainly this new agency, the NASA could do that. I think there might be launching by contractors of the National Science Foundation, for instance.

Mr. FULTON. But you would let NASA operate, for exploration of space, a peaceful space vehicle?

Dr. FURNAS. Certainly. This would be part of their function, whatever operation is required in this research and development function. This is the operation we are talking about; yes.

Mr. FULTON. You have research and development of the structure and you also have exploration of the space?

Dr. FURNAS. That is correct.

Mr. FULTON. One is Columbus and the other is von Braun. Now would you have our future Columbus of America operate under NASA?

Dr. FURNAS. He might.

Mr. FULTON. So that he would really be an operating explorer?

Dr. FURNAS. Yes, sir; you have to get out there if you are going to explore space.

Mr. FULTON. Then when we go into this radical, free radical program of yours and establish a powerplant against the opposition of the gentleman from Montana, who is for H_2O and not O_2, who is going to do that, this NASA Agency?

Dr. FURNAS. Yes; I think this would be a very appropriate function.

The CHAIRMAN. Did I hear you say rightly a moment ago that the National Science Foundation would shoot one of these peacetime satellites in the air?

Dr. FURNAS. I think they might very well do that.

The CHAIRMAN. What do you want to have another agency for? What is the use if they are both going to do it? If we are going to establish an agency we ought to give them some authority or jurisdiction.

Mr. MCDONOUGH. You must have basic research before that is done. As I understand the doctor and as I see it, the National Aeronautics Administration at the present time is a source for advanced aeronautics, that private industry has not yet tested. This agency is for the purpose of studying basic research for advanced astronautics that only the Government up to now has been interested in and private industry later may be interested in.

The CHAIRMAN. The doctor just said a moment ago, if I understood him correctly, that the National Science Foundation, in response to Mr. Fulton's question, could shoot one of these peacetime satellites in the air. Is that correct?

Dr. FURNAS. I think it might well be within their function.

The CHAIRMAN. Then if we establish this new agency, it can do it, too?

Dr. FURNAS. Yes, sir.

Mr. FULTON. You would not have passports for outer space, would you?

The CHAIRMAN. You also say the National Science Foundation has the authority now to do it and should do it in addition to the new agency?

Dr. FURNAS. Of course, the National Science Foundation is only a contracting agency. This would be one of their contracts. If it is one of the projects which they are supporting, with a research organization which calls for sending a satellite up into outer space, I do not see any reason why they should not.

Mr. SISK. Would the gentleman yield?

The CHAIRMAN. I am not arguing that, but I am trying to get in my mind these two agencies. We are likewise terminating an existing agency with too limited jurisdiction in the world of today and establishing a new one with broader jurisdiction. If we do that it seems to me that we ought to confine the jurisdiction to the one agency so far as this outer space activity is concerned.

Dr. FURNAS. I think that would be unduly restrictive sir.

The CHAIRMAN. Mr. Metcalf?

Mr. METCALF. Is the Weather Bureau going to send up a weather satellite at the same time?

Dr. FURNAS. I visualize they may.

Mr. METCALF. So there is another agency?

Dr. FURNAS. I would say it is analogous to what the situation would be if we had the restriction that only the Atomic Energy Commission could have any nuclear reactors. I think this would be highly restrictive. This was essentially the attitude initially but we have certainly gotten away from that.

The CHAIRMAN. But the Atomic Energy Commission has jurisdiction over that, does it not?

Dr. FURNAS. Only in the safety aspect.

The CHAIRMAN. The Congress passed a law connecting it with the AEC. It came out of the Joint Committee. All of that is regulated and under control of the Atomic Energy Commission, the grants, subsidies and all that in connection with these peacetime reactors. It is all connected with one agency though, is it not?

Dr. FURNAS. This, of course, ties back to the security aspect and being built of material and also with safety.

The CHAIRMAN. I am not arguing in the field of private industry. I am talking of control and jurisdiction.

Dr. FURNAS. I hope that this NASA does not get into the regulatory aspects. I think it will hinder their research projects.

The CHAIRMAN. We have gotten into the hardware angle now.

Mr. NATCHER. Doctor, you agree that the NACA is an operating agency?

Dr. FURNAS. It only operates the equipment and the facilities for its research function.

Mr. NATCHER. I agree with that. When Doctor Dryden appeared before our committee he very emphatically stated that the NACA is an operating agency, it is not an advising agency. Now you agree with that?

Dr. FURNAS. In the research and development field, yes, sir.

Mr. NATCHER. That is all.

Mr. SISK. There is a point I would like to explore then. Doctor, maybe I am thick headed but I think we are just spinning our wheels. You indicated a little while ago that the only purpose in changing the format of the NACA was to broaden its scope a little bit in view of the fact it would be confined to aeronautics, and we want to get it into astronautics.

Now you say the National Science Foundation has authority to get into this field and the Weather Bureau has authority to get into it. I don't see but what we are wasting our time. The NACA has the same authority and jurisdiction to get into it as the National Science Foundation, would it not? So that it seems to me that if we assume your position, Doctor, we have just been wasting an awful lot of time. That is my summation of the situation.

Thank you, Mr. Chairman.

Mr. KEATING. Mr. Chairman, I do not agree with the gentleman from California. I do not want my silence to be taken as agreement because I look upon this as very important.

The CHAIRMAN. The Chair will say that silence does not constitute consent.

Mr. KEATING. I do think we have put a finger on a very important matter as to how far we are going to allow this agency actually to operate because under page 7, subdivision 3, NASA is given wide operational authority in my judgment, not limited to research and development; they can even run a cafeteria under this subsection 3, which is certainly getting into operation fields.

I think we have to give a lot of thought to that section.

Mr. MCDONOUGH. It is just a function that would be necessary for any agency.

Mr. FULTON. The McCormack Astronautical Co. will not have to worry about overhead.

The CHAIRMAN. Are there any further questions of the doctor? You have stimulated some discussions.

Dr. FURNAS. I am sorry, Mr. Chairman. I apparently have confused a lot of people on the subject.

Mr. FELDMAN. I just have one more question to ask. I ask this because of the fact that you did serve on the NACA, that is on the Advisory Board or the board of directors, so to speak.

What percentage of work did the NACA do for the military that was military in nature?

Dr. FURNAS. On request from the military or of military importance?

Mr. FELDMAN. I mean of military importance.

Dr. FURNAS. I would say that probably 75 to 80 percent of the work was of military importance. It might even be higher than that. But this is very hard to define.

Mr. FELDMAN. Do you envision that when this agency is taken over by the NASA that those facilities would continue?

Dr. FURNAS. Yes, sir; for the foreseeable future this would be a large proportion of military importance.

The CHAIRMAN. Let me see if I get this clear now. Under this Agency they will have the authority to make contracts, if desired, with private companies?

Mr FURNAS Yes.

The CHAIRMAN. To do basic and applied research in connection, say, with a satellite going up into the atmosphere. You admit that they should have that power?

Dr. FURNAS. Yes, sir.

The CHAIRMAN. And at the same time the National Science Foundation should have the same power?

Dr. FURNAS. Yes, sir; if their program justifies it. I might add at this point that the effectiveness in avoiding undue duplication is going to depend primarily upon this committee or board. The membership should be made up so that you have representation of these various major activities so that you get ability in coordination.

The CHAIRMAN. I see the separation or the difference between the military at this time in the world's history clearly. But these are two civilian activities, primarily for peacetime purposes. You say they both should have this jurisdiction to compete with one another.

Dr. FURNAS. No; they should act complementary.

The CHAIRMAN. Which should be the major one?

Dr. FURNAS. As far as the amount of money spent on astronautics, the NASA should be the major one.

The CHAIRMAN. If you were to say that the NASA could make a contract with the National Science Foundation to carry out certain research work, either basic or applied, I could see the difference, but for the National Science Foundation to have original jurisdiction after we set this up in the initial stage, that is where it is difficult for me to reconcile.

If you mean the latter, I can understand that.

Dr. FURNAS. I feel that it would be a mistake to have legislation that confines all astronautical research to the NASA just as I think it would be unwise to confine all nuclear research to the AEC.

The CHAIRMAN. What other agencies are doing nuclear research besides the AEC, I mean outside of the military?

Dr. FURNAS. Various companies and various universities, various research foundations.

The CHAIRMAN. I can see a difference there but the Government has the benefit of their discoveries, does it not?

Dr. FURNAS. Not necessarily; I mean there are private companies that are doing nuclear research.

The CHAIRMAN. But in connection with Government contracts the Government gets benefit, does it not?

Dr. FURNAS. Yes, sir, if it is a Government contract that is part of your contract provision.

Mr. McDONOUGH. Speaking about the Weather Bureau operating independently or releasing a satellite, even before we released a satellite they had released balloons for checking weather conditions into outer space, had they not?

Dr. FURNAS. I have forgotten the altitude but they have sent some up quite high, 100,000 feet or so.

Mr. McDONOUGH. So that we have been exploring outer space or the upper atmosphere?

Dr. FURNAS. Yes, sir; the fringes of the atmosphere.

Mr. McDONOUGH. So as I conceive your opinion of this Agency it should be the parent agency from which the basic research on astronautics should originate?

Dr. FURNAS. Yes, sir.

Mr. McDONOUGH. And the discoveries of the Government or the military would be available to private industry for peaceful uses?

Dr. FURNAS. That is correct

Mr McDONOUGH. That is simple. It is a very important Agency in my opinion for that reason. There is no other agency that can do it.

The CHAIRMAN. You said the parent organization. You mean in relation to the National Science Foundation, for example?

Mr. McDONOUGH. Yes.

The CHAIRMAN. I am talking about the satellite going out in the air.

Mr. McDONOUGH. The National Science Foundation should seek from this Agency the authority, the regulation, the license, the privilege of moving.

The CHAIRMAN. That is different. Now you have come to my point. Is that what you meant, Doctor?

Dr. FURNAS. No.

Mr. FELDMAN. Doctor, I have just this one question. Under the type of agency that you envisage why do we need a new law to accomplish what you have in mind? Why cannot the NACA as presently set up do everything that you want done within the limit and scope that you want it done?

Dr. FURNAS. Because I think its assignment has been too restricted for this.

The CHAIRMAN. All the President would have to do is put a reorganization plan through just demoting the Board below the Director, appointing a director.

Mr. METCALF. Not even that, an Executive order.

The CHAIRMAN. I think so but I would not go quite so far as that.

Mr. McDONOUGH. I should imagine he has the authority now any way.

The CHAIRMAN. I will not go quite as far as that now, but I won't argue against one who says that.

Mr. KEATING. NACA has not anything to do with outer space.

Mr. FELDMAN. They are doing it. Doctor Dryden testified here that about 15 percent of their work last year was in outer space and that in 1959 their program calls for 25 percent.

Mr. McDONOUGH. The Weather Bureau is investigating upper atmosphere also.

The CHAIRMAN. Are there any further questions?

Mr. SISK. I would like to say one thing. I do not think there is any difference of opinion between myself and the gentleman from New York with reference to what the bill does and in reference to what we have in mind. On the other hand I do feel that should we follow the doctor's suggestion then I think we have been spinning our wheels.

I want to clarify that.

The CHAIRMAN. I agree with Mr. McDonough but the doctor does not wholly agree with Mr. McDonough.

Doctor, it has been very interesting. We ask questions oftentimes in the nature of a devil's advocate and they do not necessarily reflect our state of mind. You understand that?

Oftentimes it is from the pressing questions that the members of the committee get the most valuable information. I make that statement so that it is clearly understood that while I have asked what I thought were some pointed questions—I don't know whether

they are interesting questions, they concern me—they do not necessarily represent my state of mind.

Thank you very much. We have enjoyed having you with us. So the committee will adjourn now until 2 o'clock.

(Whereupon, at 12:55 p. m., the committee adjourned, to reconvene at 2 p. m., the same day.)

AFTERNOON SESSION

Mr. McCormack. The other members will come in, gentlemen, later. So we will proceed.

I notice that Dr. DuBridge and Dr. Pickering, both of whom we know are outstanding scientists and dedicated men come from and are connected with the California Institute of Technology.

I like to make this as informal as possible. And don't have any hesitancy in collaborating with one another.

Dr. DuBridge. Thank you.

Mr. McCormack. We want as frank expressions of views as you can give. Any question asked which involves an answer which involves classified information we want you gentlemen to just simply state so.

We are glad to have you with us, Dr. DuBridge.

The next witness is Dr. Lee A. DuBridge, president of the California Institute of Technology, Pasadena, Calif.

Mr. Keating. Before he states, may I again stake out a claim?

Dr. DuBridge was head of the physics department of the University of Rochester for a number of years before becoming president of the California Institute of Technology. And he is a distinguished scientist.

I need not tell you or the members of this committee that.

But I am particularly gratified to be on a committee where he is going to give us the benefit of his great knowledge and wonderful experience.

Mr. McCormack. I am sure we will benefit by his presence.

Mr. McDonough. Let me say, California is proud of that fact.

Dr. DuBridge. I was born in Indiana. Isn't there somebody from Indiana here?

Mr. Chairman, may I make one suggestion since my interest and whatever small competence I have in the field of space research comes from the fact that one of the divisions of California Tech is the jet propulsion laboratory which we operate under an Army contract for the Government and which has been responsible for collaborating with the Army Ballistics Missile Agency in the launching of the two Explorer satellites.

The Director of our Jet Propulsion Laboratory, Dr. Pickering, is here with me, and though we haven't collaborated on our testimony, I think our remarks will supplement each other.

May I request that immediately after my prepared statement he give his statement, and then that questions be directed to both of us and then we will share the questions between us, if that is all right with you.

Mr. McCormack. That will be agreeable.

STATEMENT OF DR. LEE A. DuBRIDGE,[20] PRESIDENT, CALIFORNIA INSTITUTE OF TECHNOLOGY

Dr. DuBridge. It is an honor to be invited to present my views on the future of space research to this committee.

The actions which the Congress will take during the coming weeks on this issue will decisively determine the role which the United States and the free world will play in this exciting field.

I suppose that the dream of "flying to the stars" has been dreamed by men ever since men have been able to dream at all. But it was not until the time of Isaac Newton that the essential physical conditions for leaving the earth were first understood. Newton himself did point out, however, that if air resistance could be eliminated then a stone hurled horizontally from a high mountain might circle the earth forever.

Newton knew also how to calculate the velocity required—by the simple process of equating the gravitational force on the object to the centrifugal reaction. For over 200 years men have been trying to lift objects high enough above the earth to get away from atmospheric friction, and then to hurl the objects with the colossal speed of about 5 miles per second which Newton's law requires.

It became clear in 1955 or earlier that modern rocket technology had advanced to the point where this feat could now at last be achieved. And it was also agreed that during the International Geophysical Year program both Russia and the United States would attempt to launch earth satellites for the purpose of obtaining scientific information.

As you know, both nations have now achieved that objective; hurling objects into orbits around the earth is no longer a dream. Objects will soon be hurled to the vicinity of the moon and before long to other parts of the solar system.

Getting beyond the solar system—out to other stars, for example—will remain still, a dream, for a long time to come for two reasons:

(1) The velocity of escape from the solar system—for an object which has escaped the earth's field—is about 26 miles per second. It takes 15 times as much energy to escape the sun's gravitational field as to escape the earth's field alone;

(2) After escaping from the solar system, it would still take 10,000 years for an object to reach the nearest star if we could again get up to a speed of, say, 18 miles per second. Stated another way, if we could give an object five times the speed—of 7 per miles second—required to leave the earth—for example, 25 times the energy—it would still take over 10,000 years to reach the nearest star.

Other stars are from 10 times to one-half billion times farther away still.

We will thus do well to stay in the solar system for the present. Thus, while we rejoice at the achievement of getting outside the earth's atmosphere for the first time, we have taken only a very tiny step into real outer space.

Yet, getting outside of the earth's atmosphere has enormous scientific advantages:

1. It lets us look at the moon, the planets, and the stars for the first time free from the blanketing effect of the air. This means we can—if we can obtain stable platforms and accurately guided telescopes—secure images free of distortion or "fuzzing" produced by air currents, and can also receive all the ultraviolet, infrared, X-rays, and radio waves now cut off by the atmosphere.

2. It allows us to look down—with our instruments or cameras—on the earth from above the air, thus seeing a large segment of the earth all at once, and getting for the first time a comprehensive view of the clouds and weather patterns as seen from above. As the earth rotates under the satellite orbit, it will have a view of the whole earth every 24 hours.

3. Outside of the earth's atmosphere we will get a new look at the earth's magnetic field, the cosmic rays, the gravitational field of the earth and the earth's exact shape and size, the radiations from the sun that presumably cause the aurora and other atmospheric effects and possibly have some effect on the weather.

In short, the possibility of having satellites taking instrumented observations at distances of from 200 to 2,000 miles above the earth's surface opens up many new fields of scientific exploration. That is the reason, of course, why a satellite program was included in the plans for the International Geophysical Year and why scientists are now so anxious to continue a large-scale satellite program.

I should like to commend to you the report of the technical panel on the Earth Satellite Program of the United States IGY Committee.

Because this sets forth the scientific exploration program that scientists have thought about carefully, I believe is a solid and useful, important program.

Mr. McCormack. How long a report is it?

Dr. Pickering. Six or eight pages.

Mr. McCormack. If there is no objection, at the conclusion of your statement we will make it a part of the record.

Dr. DuBridge. Thank you, sir. It was published in full in the New York Times. It is published in a recent issue of Science Magazine. So it is easily available.

It should be emphasized that while there are many phenomena which we know a good deal about and wish to measure more accurately far above the earth, there may be a number of wholly unforeseen phenomena which we might encounter and which will be of surpassing interest.

It is hardly fruitful to speculate as to what these unknown things might be, but the history of science is replete with examples of the new discoveries resulting from a new advance in the technique of observing or the opening up of new kinds of observations.

I think next week the International Geophysical Year Committee is going to release the results of some of the programs, some of the

information that has been obtained with the existing Explorer and Vanguard satellites.

I hear from advance rumors—but I am not in a position to give the details—that quite new things have been obtained by the cosmic ray instruments and quite unexpected results are being revealed by the Geiger counters used for cosmic-ray measurements.

This might be quite an important new thing that is being uncovered. We can expect many unexpected new things.

In my view the predominating and overpowering reason for developing a substantial program of space exploration is the vast new extension in our knowledge which this will yield and the great value which this knowledge is certain to have as it is applied, as time goes on, to the practical problems of human welfare.

However, the results of exploring space go beyond the purely scientific. It is not a matter of breathless interest to the scientist to know what the other side of the moon looks like. There is no reason to suppose that the other side hides any great new undiscovered phenomenon of nature.

Nevertheless, no human being can avoid being curious about what the other side of the moon does look like.

Man's curiosity will never be satisfied until he has a picture of it or until he actually sees it.

Mr. McDonough. The moon does not revolve.

Dr. DuBridge. It does But it revolves at the same speed that it rotates around the earth. The speed of rotation about its own axis is exactly the speed of the rotation around the earth.

Mr. McDonough. Is that the only planet that does that?

Dr. DuBridge. Yes. Well, it is really a satellite of a planet, of course. Some of the other moons of other planets may do this, we don't know.

This is not exactly accidental. This has come about because of the fact that the moon's own rotation about its own axis is damped out by the tidal friction, the loss of energy due to the tides.

This has reduced the moon's rotational velocity until it happens to match its orbiting velocity.

Mr. Feldman. Isn't that true of Mercury too?

Dr. DuBridge. No, I don't think so.

Well, we may not know. It is conceivable that other satellites around other planets might have come to the same condition.

This is the final stable condition.

(Editor's note· According to the World Almanac, Mercury always turns the same face to the sun.)

Mr. McDonough. I don't understand this control of the tides.

Dr. DuBridge. Not control. You know that the tides are produced by the moon's gravitational influence.

Mr. McDonough. On the earth.

Dr. DuBridge. Yes.

Mr. McDonough. Yes.

Dr. DuBridge. And these tides involve a very large expenditure of energy. Energy is being dissipated in the tides. As the water rises and falls this means a dissipation, a loss of energy. This energy has to come from some place. It comes primarily from the moon's own rotational energy.

Mr. Keating. Has it always been that way?

Dr. DuBridge. Of course.

What do you mean "always"? Four and a half billion years?

Mr. FELDMAN. What was it before then?

Mr. DUBRIDGE. We think the solar system was created about 4½ billion years ago. So it is only since then.

Mr. FULTON. Obviously the atmospheres around the earth and the moon revolve too.

Now, do the atmospheres——

Dr. DUBRIDGE. Of the earth. It goes with the earth.

Mr. FULTON. Yes.

Dr. DUBRIDGE. Yes. All right.

Mr. FULTON. Is there any place where it moves less fast?

Does the atmosphere just go at the same speed?

Dr. DUBRIDGE. Yes.

Mr. FULTON. Where does that stop, then?

Dr. DUBRIDGE. The top of the atmosphere?

Mr. FULTON. We don't know where the end of that is, do we?

Dr. DUBRIDGE. The atmosphere trails off exponentially. But I think you could say 500 miles above the earth the number of molecules is so small that the atmosphere is no longer there. And that there would be at that height be no longer any relation between the motion of the individual molecules and the motion of the rotation of the earth.

Mr. FULTON. Jet streams around the earth's surface of the high winds are not caused by the atmosphere slipping in.

Dr. DUBRIDGE. No. No reason why it should slip. Once it gets started, it keeps on going. But the earth's rotation plays a part in these high atmospheric currents.

Mr. FULTON. That is really what I meant.

Dr. DUBRIDGE. Because once you get a motion started, say, at the North Pole, as air flows toward the South Pole, it flows into a region where the velocity of rotation is greater.

That is the speed required to go around is greater. This means a centrifugal force that diverts the air currents and causes them to divert themselves into curious patterns.

Mr. FULTON. So it is the centrifugal force and not the slipping of the atmosphere?

Dr. DUBRIDGE. Yes.

Nor will it likely add anything to scientific knowledge when a man first travels in space. Yet we are all curious to know what space travel feels like, how a man will react to the weightlessness and other unaccustomed environment in a space vehicle—and there are many people who can hardly wait to get a "look-see" at the region beyond our atmosphere, even to the farthest reaches of the solar system.

In other words, in addition to the pure scientific interest in space there is the explorer's interest—the interest in satisfying human curiosity and human yearning. These things are important—they have been a prime urge toward human progress for thousands of years. And no one dares to say that these explorations will not yield unexpected knowledge of great value.

This weightlessness that is talked about, many people think that is due to the fact that a satellite is outside the earth's gravitational field. This is of course not the case. The earth's gravitational field is not very much less at 200 miles than it is at the surface.

Even with a thousand miles it is only 40 percent less.

25973—58——50

The weightlessness in a satellite is due to the fact that the gravitational pull is exactly balanced by centrifugal force or centrifugal reaction so the two exactly compensate.

So the net result is that the net weight is zero. But there is a gravitational force compensated by a centrifugal reaction which gives a net zero amount of weight.

Thus we should add to the scientific interest in space the explorer's interest.

These two are connected but slightly different. One could send an expedition to take measurements at the top of Mount Everest. But most explorers that have gone to the top of Mount Everest have not had scientific knowledge as their major objective.

We must also face up to the fact that during the next few years the nation that leads in the exploration of space will also gain great international prestige. I think we should be careful not to exaggerate this factor—but we should not minimize it either. The astounding impact which the first sputnik had on world opinion was a stunning surprise and shock to the American people—and indeed to our friends around the world.

However, now that five satellites have been successfully placed in orbit, the great shock of the first one has passed and it is unlikely that future space ventures will have anything like the impact of the first sputnik. Everyone knows now that sooner or later a satellite will be placed in an orbit that goes out into the vicinity of the moon. But that achievement—just because it is expected—will hardly cause the stunning shock, and hence the great propaganda victory, which Sputnik I produced.

At the same time we cannot deny the fact that if America neglects to exploit the possibilities of space exploration while Russia moves rapidly ahead our prestige will seriously suffer.

While there will be substantial propaganda advantages in carrying out a bold and an original program we must remember that we cannot expect to do everything first.

There are many things to be achieved in this field. Russia may go quietly ahead in some project they know we are not working on and therefore beat us to it once more. We should be prepared for this.

But we should move ahead and try to attain a few first of our own.

Thus the propaganda values add a third reason for proceeding with space exploration.

Finally a fourth reason. We must consider the military values associated with space exploration.

Now it is terribly important that we think our way through this field with the greatest of care.

We must not neglect any possible military gain to be attained. But we must also not waste untold billions of dollars on fruitless adventures. No task is more difficult than that of being both bold and careful.

And yet in this area we must be both.

Now, let me say at once that I do not include the development of military ballistics missiles such as the ICBM and the IRBM as space developments. I am not thinking of those in terms of space research.

It is true the long-range missiles do penetrate into space well above the atmosphere and remain there for a brief time, a few minutes. And it is necessary that we know more about this space and the problems

of leaving it and returning to the atmosphere in order to do a better job of designing missiles.

But space exploration and space research for its own sake I should like to separate from the problems directly connected with military missiles.

For one reason I don't want anything to interfere with missile development, which is a very important military goal.

It is, of course also true that rocket technology which enables us to project military pay loads for distances of 5,000 miles or so on earth also enables us, as we now well know, to project satellites into earth orbits.

Missile research therefore will contribute to space research and no doubt the reverse will also be true. In short, no one should argue against the necessity of the defense agencies working on the many problems of space investigations which are clearly related to ballistic missile development in order to speed these missile developments themselves.

May we take that for granted and then talk about other space problems, the real exploration of space as a separate category from missile development per se?

Nevertheless the military services must do more than just the pure ballistical missile work.

An earth-encircling satellite, especially one of some size, might have quite important military applications. The possibilities of surveillance and reconnaissance for example are at once obvious. The use of satellite relay stations and various types of communication problems may be important. Weather observations are of course also of military interest.

There may be other applications of which I have not heard or which no one can now foresee. Certainly a program of research in this field by the military services is of great importance for we must at least keep alert to the possibilities which our potentials may be developing.

Having said all this, however, I think it is also important that we examine our military programs with some care. In the first place we must be sure that the glamour of Buck Rogers Adventures does not divert effort and talent from more important military projects, nor lead to the expenditure of vast sums of money on projects which will not contribute to our security.

There is no use denying there are some very alluring prospects in projecting vehicles into space. It is perfectly possible now to design and build rockets and guidance equipment which, Will put large objects into orbits around the earth and into orbits which will reach the vicinity of the moon or indeed actually strike the moon and later into orbits which will reach Mars or other planets.

The major questions to be asked are, What purposes do such devices serve and how much are we willing to invest to achieve these purposes?

Also we must ask how urgent some of these needs are and whether large extra effort and funds are justified to attain results more quickly.

Now, as I say, no one would deny that reconnaissance vehicles are of great military importance. They will help us learn much about space and about the earth. Military funds of substantial amount would be justified for a broad program for such purposes. What then about weapon launching satellites?

Here I feel that the answers are less clear. Our ICBM and IRBM weapon systems themselves are so promising and require still so much

attention that it is not clear that a weapon-launching satellite system would offer the great advantages which would justify a very heavy investment in this field.

A searching analysis of this question, however is surely in order and general research in this field is very much needed. But I call your attention to the fact that to get a weapon from a satellite or to get the satellite vehicle itself, including a weapon, accurately, reliably and quickly to a particular target on the earth is a most difficut and expensive operation. While the advantages of doing it this way are still very doubtful, at least I think they cannot be taken for granted.

We very quickly then reach the question also about whether or when we should plan to send manned satellites into space for presumed military purposes.

First we must ask what the purpose of the man is in the vehicle. Is it simply to give him a ride for the sake of the stunt, the adventure? If so, let's be honest about that and then we can decide how much such an adventure is worth to the taxpayer.

Is the purpose of the man to operate scientific instruments or to take scientific observations? If so, we must ask whether unmanned scientific instruments could do the job as well for less cost. And in many cases it will be found that a man contributes nothing or very little to what could be done with instruments alone.

And the cost of sending a man up on an extended trip including, of course, the cost of his food, water, oxygen, and all the other necessary requirements plus the considerable equipment required to bring him back alive, these costs may be very high indeed.

They may add several hundred pounds to the weight of the necessary payload and thus thousands of pounds to the required gross takeoff weight.

And an equal weight of scientific equipment might well yield much more valuable results in scientific experiments.

Now many rocket scientists and technologists are in favor of pursuing unmanned vehicle experiments for the present, saving the man for the time when his presence is absolutely necessary and really contributes something and also awaiting the time when improvements in reliability of rocket equipment will give the human being a better chance of returning alive. These considerations, of course, really apply equally well to scientific or military experiments.

We must also I think give more careful attention and critical attention to the various proposals being made for military bases in space.

Shall we assemble at colossal price a big space platform to be used as a base for further exploration and for military operations?

Shall we prepare at once to establish a military base on the moon?

I would like to say that when scientists speak of the conquest of space they mean the acquisition of knowledge about it, just as the conquest of the atom meant learning to understand it.

But some people apparently have taken the term "conquest of space" to mean military conquest. That we should promptly claim certain regions of space as having been captured by America, and that the United States Forces should capture the moon and hold it by military force.

Such notions I am inclined to think are likely to be dangerous for two reasons. First they may be impractical or useless or unduly expensive without adequate military worth.

And, second, very important, they may lead directly into military conflict with other nations, when we ought to be reserving outer space for peaceful international collaboration rather than as a locale for fighting.

A base on the moon, for example, it has been said by some to be a military necessity. I believe a careful study will show this to be unsound. It is clearly easier, cheaper, faster, more certain, more accurate to transport a warhead from a base in the United States to an enemy target on the other side of the earth than to take that same warhead, together with all the men and necessary auxiliary equipment to the moon and then shoot it back from there.

And what gain can possibly compensate for this enormous cost? I trust that the United States will take the lead in urging that outer space be used by all nations exclusively for peaceful purposes. All that I have been saying emphasizes that there are large tasks of peaceful scientific research and exploration to be carried on in outer space and that in many ways the extent and importance of these scientific tasks exceed that of the military aspects of space vehicles

Since we shall wish to be working extensively with other nations on the scientific aspects of space research, because we can make much faster progress if other nations join with us, it is desirable that the civilian aspects of space research be placed under a civilian, rather than a military, agency

So I favor the prompt creation by Congress of such an agency.

One thing about such an agency is that it will be able to avoid classifying or making secret many of the things about space exploration which ought to be open to all Americans and to all the world.

I should add, however, that if the Congress should create such an agency and then proceed to vote large funds for space research only to the military agencies, then it would be better not to create the civilian agency at all. If civilian space research is to be put under a civilian agency then that agency must be provided with adequate funds for the job.

There are some people who have predicted that Congress will vote most of the funds for the space research only to the military rather than to civilian agencies.

This, I think, would be tragic. But I also think that it is an unwarranted slur against the good sense of Congress. So I would like to urge then again the creation of a civilian space agency to do the civilian space exploration, to collaborate with other nations on international scientific exploration of space, and to take care of all of those aspects of space exploration which do not have direct and immediate military applications.

Thank you very much, Mr. Chairman.

(The report referred to on p. 775 is as follows:)

BASIC OBJECTIVES OF A CONTINUING PROGRAM OF SCIENTIFIC RESEARCH IN OUTER SPACE

UNITED STATES NATIONAL COMMITTEE FOR THE INTERNATIONAL GEOPHYSICAL YEAR 1957–58

NATIONAL ACADEMY OF SCIENCES,
Washington, D. C., February 14, 1958.

Memorandum

To: United States National Committee, the Technical Panels on the Earth Satellite Program and Rocketry Program, and Chairmen of All Other USNC–IGY Technical Panels.

From: Hugh Odishaw, Executive Director.

Subject: Report on Satellite Experiments.

Herewith is a copy of the study on satellite experiments in the form that it was submitted to the President of the Academy and the Director of the National Science Foundation. This provides a few minor revisions to the earlier draft.

BASIC OBJECTIVES OF A CONTINUING PROGRAM OF SCIENTIFIC RESEARCH IN OUTER SPACE

By the Technical Panel on the Earth Satellite Program of the United States National Committee for the International Geophysical Year, National Academy of Sciences

(NOTE.—Preprinted from the April 11, 1958, issue of Science, the weekly journal of the American Association for the Advancement of Science)

1. INTRODUCTION

The International Geophysical Year marks the beginning of man's exploration of outer space. There have been previous rocket firings into the fringes of the earth's atmosphere, but the expanded rocket-sounding program on an international scale and the advent of artificial earth satellites represent by far the largest steps taken toward the scientific exploration of outer space and the planets.

The interests of human progress and our national welfare now demand that a long-term program of space exploration be formulated and pursued by the United States with the utmost energy. Although there will inevitably be benefits from such a program of a very practical nature, the basic goal of this exploration must be the quest of knowledge about our solar system and the universe beyond.

The scientific program proposed here has been formulated with the following ideas in mind:

(i) Technology of space flight will probably develop gradually. Therefore, the payloads and distances traveled will be relatively small at first, and the scientific experiments and observations will be correspondingly modest in the early stages.

(ii) The scientific program should be designed to give information at each stage which will help in the planning of later flights.

(iii) Manned space flight will occur in the course of the program, but before this occurs certain crucial experiments must be performed which are aimed specifically at the design of a manned vehicle.

(iv) In the quest for outer space we must not lose sight of the tremendous implications to life on earth which the occupation of space will have.

The experimental program proposed in this study represents concepts and views of many scientists, but particularly those involved in the current IGY satellite effort. Of the latter group, the USNC–IGY Technical Panel on the Earth Satellite Program and its three working groups have in one way or another contributed to the thoughts expressed in this paper. The membership of these groups follows:

Technical Panel on the Earth Satellite Program: R. W. Porter (Chairman), G. M. Clemence, Michael Ference, Jr., Joseph Kaplan, Homer E. Newell, Jr., Hugh Odishaw, W. H. Pickering, A. H. Shapley, Athelstan F. Spilhaus, James A. Van Allen, Fred L. Whipple, J. G. Reid (Secretary).

Working Group on Internal Instrumentation: James A. Van Allen (Chairman), Leroy R. Alldredge, Michael Ference, Jr., Herbert Friedman, William W. Kellogg, Hugh Odishaw, R. W. Porter, O. H. Schmitt, Lyman Spitzer, Jr.

Working Group on Tracking and Computation: W. H. Pickering (Chairman), G. M. Clemence, W. A. Heiskanen, G. P. Kuiper, J. T. Mengel, J. A. O'Keefe, J. E. Steakley, Fred L. Whipple.

Working Group on Satellite Ionospheric Measurements: A. H. Shapley (Chairman), W. Berning, George Grammar, C. Gordon Little, Wolfgang Pfister, J. C. Seddon, Ralph J. Slutz, G. W. Swenson, Jr., O. G. Villard, Jr., A. H. Waynick, H. W. Wells.

An earlier study of the Panel in this area was prepared by R. W. Porter, J. A. Van Allen, H. E. Newell, W. W. Kellogg, and Lyman Spitzer in January 1957. The present proposed program, based on the earlier report, but considerably extending the scope of experimental possibilities, was prepared by W. W. Kellogg in collaboration with the Panel and the Working Group on Internal Instrumentation.

2. SOUNDING ROCKETS

Sounding rockets have provided so much information about the upper atmosphere and its effects on incoming radiation of various kinds that they will continue to be useful in this area. A continuing program using such rockets should be aimed at determining the distribution *in the vertical* of such quantities as:

(i) Atmospheric composition.

(ii) Atmospheric pressure, temperature, and density.

(iii) Winds in the upper atmosphere.

(iv) Atmospheric ionization.

(v) The absorption of electromagnetic radiation penetrating the atmosphere and the intensities of sources of such radiation in the atmospheric layers.

(vi) The absorption of cosmic-ray or solar particles, and the secondary effects of these particles.

(vii) The geomagnetic field (also covered under satellites).

(viii) Detection and location of electric-current systems in the atmosphere.

(ix) Experiments requiring recovery of packages. (See below.)

With a sufficiently intense program, it will be possible to detect latitudinal, diurnal, and seasonal changes of these quantities, and also

the ways in which they are modified during periods of solar activity and magnetic storms.

Until the techniques for the recovery of packages from a satellite have been worked out in more detail and demonstrated, there will be a class of experiments requiring the return of various kinds of samples for which the vertical rocket is required. These may involve:

(i) Film samples: Photographs, spectrographic data, cosmic-ray packets, or data recordings where the quantity of information is too great to telemeter.

(ii) Biological samples.

Experiments which will probably not be suitable for sounding rockets in the future, with the availability of earth satellites of progressively larger payloads, are solar or astrophysical observations, particularly those in which time changes are sought. Clearly, a satellite vehicle is superior for such observations.

3. EARTH SATELLITES

An earth satellite is considered, for these purposes, to be a vehicle which is on an orbit controlled primarily by the earth's gravity. (This means, in effect, something less than 1,000,000 miles from the earth and with insufficient velocity to carry it further.) Even when the technology of space flight has progressed far beyond the ability to put satellites on orbit and vehicles are being directed on heliocentric and interplanetary missions, the earth satellite will surely continue to be a base for fruitful observations.

Fundamentally, a satellite well outside the earth's atmosphere can be used to observe only three kinds of things, namely: photons, particles, and fields.

The photons, since they represent electromagnetic radiation, may range from X-radiation and ultraviolet radiation to radio waves. In general, when dealing with photons coming from remote sources in the sun or beyond, the purpose of a satellite is to observe the wavelengths which do not penetrate the earth's atmosphere. This implies that the radiation of primary interest is at wavelengths below the ozone cutoff in the ultraviolet (about 0.32 microns) and at wavelengths above the ionospheric cutoff in the radio wave region (about 30 m., or 10 Mc.). Most of the radiation in between these limits penetrates the atmosphere and can therefore be observed on the ground or from balloons, except for some important, but limited, regions in the infrared where water vapor, carbon dioxide, and ozone cause absorption.

In addition to observing these highly significant radiations from above, the satellite will be of great value in observing the earth, its changing cloud patterns, its infrared radiation, etc. These are discussed further below.

The particles which can be observed from a satellite are solid meteoroids of various sizes and atomic nuclei with great energy emanating from the sun and beyond (auroral particles and cosmic rays). These are both of great significance to the development of manned space vehicles, since the solid particles constitute a hazard to the vehicle due to their ability to puncture its skin, and the atomic particles may be a hazard to the man inside.

The fields which are measurable from a satellite are the field of gravity and the magnetic field. The first, the field of gravity, is related to the masses and shapes of the earth and moon, and satellite observations promise greatly to improve the precision of our knowledge of these quantities. Magnetic field measurements not only tell about the magnetization of the earth and moon, but also tell about the electric current systems which flow in the vicinity of the earth.

Since a great deal has already been written about the uses of an artificial satellite, the following experiments are presented in outline rather than in detail. First are those which could be done in Vanguard-type satellites, assuming a growth potential in payload to 50 or 75 pounds and a wider choice of orbits than is available under the IGY program. With larger payloads and more advanced techniques there are some more elaborate experiments which could be done, experiments which require stable platforms, large transmission power and information band width, recovery of packages, etc. Finally, there will be manned satellites.

4. LIGHTWEIGHT SATELLITE EXPERIMENTS

(*a*) *Creation of visible objects.*—There are a number of reasons for wishing to have an easily visible satellite. In particular, precision orbit determinations will probably be done optically, and it is clearly desirable to have a satellite which reflects or emits a considerable amount of light. At night a flashing light with a brightness of 10^6 candlepower or more would be just visible at about 1,000-mile range, provided the duration was about 0.1 second or more. An alternative method is the creation of a large reflecting object such as a balloon or erectable corner reflector. Such an object to be seen optically or visually must be near the twilight zone of the earth, so that the observer can see the sunlit reflector against a darkened sky. Under such conditions a 100-square-foot diffuse reflector appears like a first magnitude star at about 200 miles (depending on the angle between the sun and observer), and can still just be seen by the naked eye at about 2,000-mile range. Naturally, with telescopes one can do much better, if one knows ahead of time where to look for the satellite.

With the sort of precision orbit determinations which can be obtained with optical tracking it is possible to do a number of important things, namely:

(i) Determination of air drag at high altitudes, from which atmospheric density can be derived. A possible complication here is the effect of an electrostatic charge on the satellite, and the interactions between this charge, the ions present in the ionosphere, and the earth's magnetic field.

(ii) Geodetic measurements on the size and shape of the earth.

(iii) Lunar mass, for orbits passing near the moon.

(iv) Ion densities, when coupled with certain precision radio techniques.

(*b*) *Total atmospheric thermal and visible radiation measurements.*—A satellite is in an ideal position to measure the total flux of radiation in and out of the top of the atmosphere. The incoming radiation, being primarily from the sun, is largely in the visible part of the spectrum, while the outgoing radiation from the atmosphere is infrared plus the solar radiation which is scattered and reflected upward. These va-

rious fluxes can be sampled by a set of omnidirectional bolometers with coatings which are designed to absorb selectively a certain part of the spectrum. For example, a bolometer which is white in the visible but black in the infrared beyond about 4 or 5 microns, will respond to the thermal radiation from the earth and atmosphere, while one with the reverse spectral characteristics will measure the direct and reflected sunlight. Further, a directional detector of visible radiation pointed toward the sun would, of course, monitor the incoming solar radiation alone. (Such a scheme is included in one of the IGY earth satellites.)

The purpose of this set of measurements is to determine the radiational heat budget of the earth and atmosphere. It is known that an excess of radiational energy is added to the atmosphere in low latitudes and that here is generally a net loss of energy from the polar regions. An understanding of this energy imbalance is basic to an understanding of the general circulation of the atmosphere. Further, such a set of radiation measurements, provided that there were a reasonably fast response, would give a rough indication of the thermal inhomogeneity of the atmosphere and earth. It is likely that a measure of this inhomogeneity would provide an indication of the strength of the cyclonic and anticyclonic circulation. During periods of strong meridional transport of energy by the atmosphere there are rapid migrations north and south of warm and cold air masses, and these could probably be distinguished by their thermal characteristics.

(c) *Mapping the cloud cover.*—On the sunlit side of the earth the contrast in the visible and near infrared between clouds and ground or open water is considerable, and it has been demonstrated dramatically by the use of rocket and balloon photography that the existing weather can be traced by the large area cloud patterns. These cloud patterns can be determined from a satellite by various means. A first approach, in which the scanning of the surface by photocells is performed by the uncontrolled rotation of the satellite, is being developed for the IGY program. In this case the reconstruction of the picture is complicated, however, and the data handling capacity of the telemetering link places an upper limit on the amount of coverage and degree of resolution.

The purpose of such an observation would be to show the cloud patterns over a large area of the earth with a degree of completeness unobtainable with present surface observation networks. For research in meteorology, this will throw new light on the way in which storm systems start and develop, on the broad pattern of flow, on the effects of mountain barriers, etc. If refined to the point where the observations can be made available to meteorologists immediately, it would represent one of the greatest advances ever made in meteorological data gathering, and would surely improve short-term forecasting and hurricane predictions.

(d) *Mapping the night airglow and aurorae.*—The upper atmosphere in the 70 to 150 km. region continuously emits ultraviolet, visible, and infrared radiation. In middle and low latitudes this emission, called the "night airglow," is relatively steady but displays moving patterns. As is well known, the aurorae of the polar regions are tremendously variable. A worldwide survey on the dark side of the earth of this radiation, in the general manner of the cloud cover experiment but with greater sensitivity and less angular resolution, would provide a

map of the activity of the emitting layers. The brightest lines of the upper air emission spectrum are the familiar 5,577 A. and 6,300 A. lines of atomic oxygen, the 5,893 A. doublet of sodium, the OH bands in the ultraviolet and infrared, and the O_2 "atmospheric bands" in the infrared. The last mentioned may be the brightest of all when observed from outside the atmosphere.

The airglow and aurorae present moving complex patterns which must be related to the meteorology of the 70 to 150 km. region. The map of the emission in various wavelengths from the ultraviolet into the infrared would therefore be an invaluable aid in studying the behavior of this important part of the atmosphere. It is significant to note that changes in solar emission are undoubtedly first signaled by changes in the circulation patterns in this same region of the atmosphere, and that these changes probably then work downward to affect the lower atmosphere.

(*e*) *Time fluctuations of solar ultraviolet and X-radiation.*—Solar ultraviolet and X-ray intensities are quite variable, and appear to depend greatly on solar activity. Both X-rays and the ultraviolet are enhanced during a solar flare, in some wavelength regions by an order of magnitude or more. These fluctuations have corresponding effects in the earth's atmosphere. Increased output of hard X-rays, for example, causes a pronounced D layer and an associated interference with radio communications. An increase in the intensity of near ultraviolet solar light could contribute to the marked temperature excursions that have been noted in the ozone layer, and such temperature excursions undoubtedly interact with the surrounding wind patterns.

Since solar ultraviolet light and X-rays have such a pronounced effect on the atmosphere and since their fluctuations are associated with important related effects, it should be very fruitful to monitor these solar wavelengths over a long period of time, say for a year, for the purpose of correlating the ultraviolet and X-ray intensity-time curve with weather, radio propagation, the ionosphere, airglow, winds, etc. Because these solar radiations are absorbed by the atmosphere, the logical place to monitor them is from above the appreciable atmosphere. This could be done in an artificial satellite orbiting entirely above 200 miles altitude. By using suitable windows and gas fillings, photon counters and ionization chambers can be constructed to respond only to radiation within a restricted band. (Such a photon counter, sensitive to Lyman-alpha radiation, is being flown on an early IGY satellite.) With such detectors, various bands from the near ultraviolet down to the hard X-rays could be monitored. Payloads on the order of 50 pounds should be adequate to permit coverage of a number of important wavelength bands in a single installation having indefinite duration of operations.

(*f*) *Distribution of hydrogen in space.*—The hydrogen population of interplanetary and interstellar space has been a subject of much interest and speculation. On the basis of astrophysical observations, the current estimate is about 1,000 atoms per cc. in interplanetary space and about 1 atom per cc. in interstellar space, but the basis for this is uncertain.

The density of hydrogen in space could be determined by observing the hydrogen Lyman-alpha radiation received from space and comparing it with direct solar Lyman-alpha radiation. Hydrogen ions in

space would emit a more or less steady background of Lyman-alpha as they captured electrons. Hydrogen atoms would fluoresce under irradiation by solar Lyman-alpha, and this fluorescence would fluctuate directly with the solar curve. By analyzing the total Lyman-alpha intensity into the steady and solar-dependent components, one could then determine the relative densities of hydrogen ions and atoms. With suitable calibration, the absolute densities could be determined.

The ionization chambers to be used to study solar Lyman-alpha radiation from an IGY satellite could also be used as the detectors for the hydrogen-density experiment.

A valuable refinement of this type of observation would be the measurement of the contour of the Lyman-alpha line with high resolution, possibly using a very high order of reflection from a ruled grating combined with photoelectric scanning Such a technique is capable of a resolution of a few hundredths of an angstrom, which is adequate to reveal the existence of an absorption core in the center of the line. Continuous measurements of this type from the satellite would reveal any temporal variation in the depth of the core of the line, and such measurements could give information about variations in the total neutral hydrogen content between the satellite and the sun, and the temperature of interplanetary hydrogen.

(*g*) *Survey of celestial sources in the far ultraviolet.*—Exploratory measurements made with rockets reveal a very different picture of stellar magnitudes in the far ultraviolet than in the visible. Not only do the stellar emissions show anomalies in the ultraviolet, but intense emission from ionized gas clouds has also been observed.

A satellite equipped with ionization gauges or photon counters with high sensitivity and restricted view would permit a scanning of the sky with better aspect control than is possible with rockets, and would provide a rough map of the ultraviolet "hot spots." Subsequent satellites with better orientation control could then survey these sources in more detail.

(*h*) *Extragalactic light.*—Among the many radiations which strike the top of the earth's atmosphere, the light from sources beyond our own galaxy is one of the most interesting, insofar as it contributes to the profound understanding of the astrophysical nature of the universe. The intensity of this extragalactic radiation is already known to be quite weak in comparison with the light from our own galaxy, and its spectral character is known to be heavily shifted to the red. These facts alone are subject to an immediate cosmological interpretation, viz, the expanding nature of the universe.

The expanding-universe hypothesis can be submitted to more specific test by detailed measurements of the spectrum of extragalactic light and by the distribution of its intensity with respect to galactic latitude.

Such observations are impossible with ground-based or ballon-borne apparatus due to the great overburden of other radiations originating in the earth's upper atmosphere. They might be thought possible with vertically fired rockets which surmount the major emitting layers of the atmosphere, but the intensity is judged to be so weak that the several minutes of a rocket flight provide an inadequate period of time for significant measurement. The long-time duration of a satellite's flight appears to be necessary in order to accumulate significant data.

The proposed apparatus consists of several high-sensitivity, photoelectric telescopes equipped with a variety of spectral filters—all

operating in the visible region of the spectrum. This experiment seems properly classified as an exploratory one. Results are not assured, but if they are obtained they will be of very far-reaching and profound significance.

(*i*) *Cosmic-ray observations.*—The objectives of a cosmic-ray experiment would be (*a*) to make comprehensive observations on the total intensity of the cosmic radiation as a function of latitude, longitude, altitude, and time; (*b*) to investigate the presence of the nuclei of lithium, beryllium, and boron in the primary cosmic-ray beam, and, if present, to measure their intensities; and (*c*) to study, as in (*a*), the intensity of the heavy nuclei separately from the total intensity. Interpretation of the results of (*a*) and of (*c*) should yield a crucial test of the theory of the deflection of charged cosmic-ray particles approaching the earth through the geomagnetic field and should yield new information on the nature and importance of interplanetary magnetic fields. The data of (*b*) should settle one of the leading questions on the astrophysical origin of cosmic rays and on their propagation to the earth. The data from (*a*) and (*c*) should provide a greatly improved understanding of the systematic and sporadic fluctuations of the primary radiation, their astrophysical causes and their consequences on the rate of secondary cosmic-ray phenomena within the atmosphere. A special question is whether the solar sources of cosmic rays yield the same distribution of nuclear species as that of the usual primary beam.

(*j*) *Primary auroral particles.*—The polar aurorae ("northern and southern lights") are caused by the interaction of energetic charged particles with the upper atmosphere. Due to their charges, they are deflected by the earth's magnetic field and are focused on the polar regions. It has been established that the intensity of these streams of auroral particles changes rapidly, apparently due to changes in the sun.

In order to observe these particles, it would be necessary to have a satellite on a high-inclination orbit, since the flux is concentrated toward the poles. By means of simple satellite-borne detectors it will be possible to map out the impact zones of the primary auroral particles on the top of the earth's atmosphere and to observe their changes locally and worldwide with time to a degree not ever likely to be approached by ground observatories. It will be possible rapidly to compare the northern and southern zones of incidence and to study efficiently the ways in which the position and configuration of these zones are influenced by and correlated with geomagnetic field disturbances.

The temporal variations of the incidence of auroral radiations can be comprehensively correlated with observable activity on the sun to an extent not presently conceivable by any other method. In addition, the nature of the primary auroral radiations (e. g., protons, electrons, heavy particles, etc.) can be comprehensively studied, as can their intensities and energy spectra. A comparison of these data with those from ground observatories should be very fruitful in establishing the physical processes which are induced in the earth's atmosphere.

These auroral observations are closely related to observations of the geomagnetic field. Indeed, it would be desirable, for mutual support, to have two satellites aloft simultaneously—one carrying

a magnetometer and the other carrying auroral radiation detectors. Eventually it may be possible to have a single satellite carry both types of apparatus

(k) *Micrometeorites.*—There are various estimates of the number of micrometeorites striking the earth's atmosphere, but few actual measurements. For the IGY it is planned to count such particles in one or two satellites. The limited instrumentation and limited time of operation of the equipment will, however, leave unanswered such questions as: What is the mass spectrum? What is the energy spectrum? What are the fluctuations in total intensity? How are these particles related to visible meteor showers? In a satellite capable of operating over a period of a year, most of these questions could be answered using calibrated microphones, thin diaphragms with photocells to observe punctures, electrostatic analyzers, and the like.

(l) *Magnetic field.*—The earth's magnetic field is mainly due to the magnetization of the earth's mantle and the electric currents flowing in its liquid core, a property which can be quite accurately measured by ground-level surveys or aerial reconnaissance. However, the variations in this main field of external origin, amounting to as much as 7 percent, say, are due to a variety of current systems in the ionosphere and above. (There are current systems induced in the earth also, but these are presumably secondary effects due to the phenomena at great altitudes.) A major source of geomagnetic variations are the direct current systems in the lower part of the E region, which are below the satellite altitudes. However, at much greater distances, perhaps an earth radius or more, there may be another highly variable current system known as the "ring current."

With a satellite-borne magnetometer flying over a monitoring magnetometer on the ground making a simultaneous measurement of the magnetic field, it is possible to determine the horizontal flow of current between the ground and the satellite. The same technique can be used with two satellite magnetometers as they pass over each other. Thus, it is possible to map the electric current systems out through the region of the ring current.

The use of vertical rockets to do this same thing has already been mentioned. In some ways a rocket is superior to a satellite for magnetic measurements, since it can make a vertical profile from the ground up and thereby determine where the electric currents lie. However, these currents are highly variable, and a satellite permits a determination of how they vary in time, how they are related to solar activity, and how they may vary in the horizontal. The ideal approach would be to use rockets and satellites in combination, thereby obtaining a more complete map of the geomagnetic field in three dimensions and in time.

(m) *Ionospheric observations.*—The ionized layers of the ionosphere (D, E, F_1, F_2) generally lie between 80 and 300 or 400 km. They are, therefore, mostly below the level of the satellite. A number of effective methods have been suggested for measuring the total free-electron density between the satellite and the ground, one being a measure of the difference between the angle of incidence of the radio-tracking signal and the optical line-of-sight as the satellite passes over a tracking station. The difference is very small and barely measurable for the radio frequencies best suited for tracking and

telemetering. In order to insure accurate tracking, the USNC-IGY satellites transmit primarily at 108 mc. However, a 40-mc. transmission is also planned for some USNC-IGY satellites, one of the frequencies used in the Soviet satellites, and at this lower frequency more bending and dispersion of the radio waves will occur. The use of some of the techniques of radio astronomy would be appropriate to measure this effect. The addition of two or more frequencies simultaneously would give added meaning to the results. Another observation yielding total electron densities is the rotation of the plane of polarization of the radio wave due to the Faraday effect. Such an observation requires a high gain antenna with a dipole to sense the plane of polarization and a knowledge of satellite orientation

Another class of satellite radio experiments would make use of the satellite as a known source of radiation to measure certain aspects of the fine structure of the ionosphere. It is observed that radio stars fluctuate, and these fluctuations are in part due to ionospheric inhomogeneities of various sorts, some of which are in the E region and some in the F region. A satellite would permit a mapping of these horizontal inhomogeneities (sometimes known as ionospheric lenses), both in the horizontal and in the vertical. Since the satellite may at times be in or below the F region, it will be possible to separate out the various effects of the two regions of inhomogeneity. An especially interesting aspect of the irregularities in ionization of the upper atmosphere is the pattern of the auroral clouds, streamers, draperies, etc., which extend from the E region upward to great heights. These patterns are marked by visual radiation, as is well known, but they are also regions of intense local ionization. The radio signal from a satellite in the auroral zone would be influenced by the auroral ionization, and presumably a study of the fluctuations would tell a great deal about the character and distribution of the ionization in this region.

It should be borne in mind that the gross structure of the ionized layers can be measured from the ground continuously with inospheric recorders, and that the general features of the ionosphere are already quite well understood. Furthermore, it was pointed out above that the fine structure of the ionospheric layers can probably best be obtained by a rocket which penetrates rapidly through the ionosphere, recording successive changes in "radio depth" as it goes. However, it is certain that valuable ionospheric experiments can be made using satellite radio transmissions, and the experiments described above will be possible with any satellite which provides a more or less steady signal with stable frequency and known polarization.

To date, no experiment has been proposed which can measure the free electron distribution above the top of the ionosphere from a single satellite without serious difficulties due to the dominant effects of inhomogeneities in the ionosphere itself and uncertainties in the orbit, which tend to mask any second order effects at the satellite altitude. However, the distribution of free electrons above the ionosphere would be of great significance. The use of two satellites, with a two-frequency transmission link between them, offers an apparently feasible solution. Another possible technique would be the use of a miniaturized sweep frequency ionospheric sounder in the satellite, directing its pulses downward.

(*n*) *Biological experiments.*—Biological experiments should be instituted at the earliest opportunity in the satellite program, since they will be crucial to the eventual attainment of manned space flight. There appear to be two main areas of concern: The biological effects of prolonged exposure to the radiation in space, ranging from cosmic rays to the various solar emissions, and the subtle and complicated effects of prolonged weightlessness.

With regard to the first, a program of exposure of biological samples and live animals to cosmic radiation at high altitude by balloons has been underway for some time, and at the altitudes attainable by balloons (over 100,000 feet) the cosmic radiation is essentially the same as at satellite altitudes. There are other kinds of radiation, such as solar ultraviolet and X-rays, which do not penetrate to balloon altitudes, but these can be reproduced conveniently in a laboratory. Thus, the use of a satellite for the study of radiation effects on biological specimens does not appear too rewarding.

For the study of prolonged weightlessness, on the other hand, there is no known substitute for a vehicle floating freely in space. Biological specimens and live animals have been successfully flown and recovered from high-altitude rockets, having been exposed to a few minutes of weightlessness. The second Soviet satellite carried a dog, thereby lengthening the duration of the period of weightlessness ad mortuum. The USNC–IGY satellite program includes a biological sample (yeast). These first attempts to study weightlessness will have to be greatly expanded in the future.

5. ADVANCED SATELLITE EXPERIMENTS

(*a*) *Selective and directional thermal radiation measurements.*—Since certain constituents of the atmosphere, such as water vapor, ozone, and carbon dioxide, have strong absorption lines in the infrared region of the spectrum, a detector looking downward which is sensitive only in these regions does not "see" the earth's surface. Instead, it detects the radiation emitted upward from the upper levels of the constituent, the radiation from the layers below having been absorbed by the atmosphere. Thus, for example, a detector looking down at around 9.6 microns (in a strong ozone band) would receive the thermal emission from the top of the ozone region at about 10 to 30 km. altitude; a detector looking down at around 6 microns (in a strong water-vapor band) would receive the emission from the top of the troposphere at 8 to 10 km., above which there is relatively little water vapor. A quantitative measurement of the thermal radiation in one of these narrow spectral intervals gives a measure of the temperature (and, to a second order, density) of the emitting layer. A more detailed analysis of the variation of this emission with zenith angle can give the vertical distribution of temperature in the emitting layer. This experiment would require great detector sensitivity and a considerable degree of orientation control, particularly the measure of the "limb darkening" just described. To be most meaningful, the record for an entire satellite circuit should be complete, probably requiring data storage and retransmission over a telemetering station.

The purpose of such a set of measurements would be to map the effective temperature of various layers high in the atmosphere. Some of these layers are inaccessible to conventional sounding balloons, and

even those which are accessible can only be sampled at a few points. As meteorologists have obtained progressively more information about the synoptic conditions in the upper atmosphere (using balloons and occasional rockets to date), they have gained more insight into the behavior of the atmosphere, and weather forecasting ability has gradually improved. However, balloons cannot penetrate the part of the atmosphere which is affected by solar ultraviolet radiation below about 0.3μ (the ozone cutoff). It seems reasonably certain now that short-term changes in solar radiation have an immediate effect on parts of the upper atmosphere, and that these effects propagate slowly downward in a complicated and as yet unexplained way. A synoptic satellite observation of the kind described would probably provide a direct measurement of the immediate effects of a solar disturbance on the thermal structure of the atmosphere. It would, therefore, be a key to the development of a physical basis for long-range weather prediction.

(*b*) *Selective and directional ultraviolet and X-ray measurements.*—As already pointed out, ultraviolet and X-radiation from the sun below about 3,000 A. does not reach the surface, but is absorbed and scattered by various constituents of the upper atmosphere. In some wavelengths this radiation is absorbed in a relatively limited region. Thus, if one scanned the sunlit atmosphere from above, using a number of ultraviolet detectors, one would be able to obtain a vertical profile of several of the constituents. For example, scanning with photon counters sensitive to 1,400–1,100 A. it is possible to survey the vertical distribution of O_2 from the 100-km. level to the top of the ionosphere. At around 2,500 A. one could determine the distribution of O_3 below 100 km. Similar measurements in X-ray wavelengths would monitor density variations in the E and F_1 regions of the ionosphere.

These types of measurements have been proven in rocket experiments. With sufficient payload available, more refined spectroscopic surveys of the earth's atmosphere in the far ultraviolet should be possible using the sun as a light source and measuring its attenuation or studying characteristic resonance lines of the various constituents.

(*c*) *Astronomical spectrograms.*—A spectrograph mounted in an artificial satellite would be able to photograph the sun, planets, and stars completely free from interference by the atmosphere, thus extending the sensitivity far into the ultraviolet end of the spectrum and permitting a much more detailed study of these bodies than is now possible.

Spectrographs to do this job are, in essence, available. Suitable light collectors would have to be designed. A pointing control would be necessary. Such a control could probably be worked out much along the lines of those now used in rockets, and would have a total weight less than thirty pounds. To retrieve the film, it would be necessary to work out techniques for recovery of a capsule from the satellite orbit (or of the satellite itself); however, such techniques have already been proposed and are considered to be feasible within the expected weight limitations.

An alternative to the recovery of film is, of course, the electronic processing and telemetering of these observations. This is discussed further in the next section.

(*d*) *Ultraviolet photographs of the Sun.*—Much of the photochemical and dynamical activity in the sun is associated with the emission of

ultraviolet radiation. Photographs of the sun in various regions of the ultraviolet should permit localization of regions associated with the respective wavelength emissions, and would be an important aid to understanding solar activity.

Suitable filters and UV sensitized films are available for making such photographs. If necessary, pointing controls similar to those already used in rockets could be constructed for directing a camera at the sun. It would probably be desirable (but not necessarily essential) to recover the film after the pictures had been taken; however, as indicated in experiment (*c*), it is believed that suitable techniques could be developed for the recovery operation.

In this type of experiment, the use of photoelectronic recording and telemetering should certainly not be overlooked, however. Such a technique would be a great advantage, for example, if a more or less continuous picture was needed. A variety of approaches can be considered for obtaining photoelectronic pictures of the sun in the ultraviolet or X-ray region. For example, it is entirely possible to measure the distribution of Lyman-alpha over the sun's disc by a photon counter with narrow field of view, sensitive to this line only. By using a simple scanning motion, a crude picture equivalent to a television scan of about 20 lines resolution is even possible in a rocket experiment, and the longer time available in satellite measurements would permit such scans to be made with more resolution and in other interesting wavelengths such as the helium resonance lines at 584 and 304 A, the MgX line at 625 A., and in various X-ray wavelengths.

(*e*) *Planetary spectrograms.*—A variation of experiment (*b*) would measure the spectra of the various planets in the ultraviolet and infrared. All of the central planets have visible atmospheres, but the composition of these atmospheres is difficult to observe spectrographically from the ground due to the presence of the same or similar gases (in differing proportions) in our own atmosphere. For example, the solar ultraviolet radiation reflected from these planets is completely absorbed by our atmospheric ozone, and large segments of the infrared radiation which is emitted are absorbed by water vapor, carbon dioxide, and ozone, plus other trace constituents such as methane, nitric oxide, etc. A satellite would have a clear view of these planets.

The radiation from them is very weak, however, and would require quite accurate positioning of the spectrograph in order to provide long exposures with limited angular fields (in order to minimize the cosmic and stellar background). Moreover, it would probably be most desirable to recover the spectra in the form of exposed plates, though it is possible to telemeter the information to the ground.

(*f*) *An experimental test of the general theory of relativity.*—One of the predictions of the general theory of relativity is that the fundamental time scale of atomic phenomena (e. g., frequency of emitted spectral lines) is influenced by the gravitational potential in which the emitting system is located. This prediction has received thus far only a very few observational verifications, and even these remain in a somewhat controversial state. It is conceivable to mount a so-called caesium or thalium "clock" in a satellite and a similar one at a ground station and intercompare the rates of these two clocks over an extended period of time. By the general relativistic theory, it is expected that there would be a systematic difference in the rate of running of these two

"atomic clocks" due to the known difference of gravitational potential to which they are subjected.

The effect is a small one, and it appears that accumulated observation over a period of the order of a month may be required to surmount reasonable experimental errors in location of the position of the satellite and in ionospheric conditions. (Both effects, of course, influence the transit time of the transmitted intercomparison signal from the satellite to the ground station.)

A proposal is known to be currently under consideration for a similar intercomparison between clocks, one of which is located on a mountain and the other in a neighboring valley. However, if the technical problems can be adequately solved, it may be desirable to utilize a satellite for a more sensitive test of this very profound theoretical hypothesis under different conditions.

(*g*) *Solar (cosmic) radio noise in the HF and LF spectrum.*—High-frequency radio waves below about 5 mc. cannot penetrate the ionosphere, and even radio waves at 20 mc. are sometimes totally absorbed. Thus, it is not possible to observe from the ground the lower frequency end of the radio noise which comes from the sun and beyond.

A satellite would, of course, not suffer from ionospheric absorption, but the signal levels in this region are low and the antennas required to obtain much gain have to be large. However, by using long wires, or large erectable reflectors or lenses to concentrate the signals and to obtain directionality measurements could be made on HF signals below the ionospheric cutoff.

(*h*) *Collection of micrometeoritic samples.*—If the techniques can be worked out for recovery of the satellite or of small capsules from the satellite, a long-period collection of micrometeorite particles could be obtained. These samples could be collected in containers filled with something like silicone grease, which could be opened while the satellite is on orbit and then closed just before the recovery operation was begun.

The recovery of a representative sample of meteoric material would be of value for a number of reasons: It would throw light on the relative abundance of elements in the solar system; it would help to resolve the questions concerning the scattering effect of this dust, observed as the zodiacal light; it would supplement the previously mentioned satellite observations of meteors by their impact effects, etc.

(*i*) *Manned satellites.*—In section 8, manned space flight is discussed briefly, and it is pointed out that man will inevitably venture into outer space sooner or later. Whether the presence of a man in the vehicle will contribute to our knowledge of the universe is beside the point. Such an achievement should, perhaps, be considered as an end in itself—the ultimate biological experiment.

6. LUNAR INVESTIGATIONS

One of the major justifications for building and launching a rocket to the moon is the knowledge which would be obtained about our nearest neighbor in space. The emphasis of the long-range program described here is on an orderly progression of technical development and scientific research into problems of outer space. In this context, the investigation of the moon is but a step to the investigation of the planets.

There are several potentially fruitful experiments and observations on the moon, some of which could be done by impacting the moon directly (the impact velocity would be about 9,000 foot-seconds for a vehicle taking 2 to 3 days for the trip), some of which could be done by a circumlunar orbit (which would be a special kind of satellite), and some of which would require the lowering of instruments to the surface. Ultimately there will be manned vehicles capable of landing on the moon.

The early experiments which should take priority are, in general, those which give information about the moon *as a whole*, rather than about the particular point of impact. These will reveal the most about the processes by which it was formed, its past history, and so forth, and will be most useful in planning for subsequent experiments. The three quantities to be measured which pertain to the moon as a whole are the lunar gravity or mass, its magnetic field, and its atmosphere. Of these, probably the last is the only one which requires landing on the moon. A further experiment, described more fully below, is the determination of the internal structure of the moon by seismic prospecting techniques—this will certainly require the landing of an instrumented package.

(*a*) *Measurement of lunar mass and gravity.*—Present estimates of the moon's mass, based primarily on observations of the motions of asteroids and of the motions of the earth's polar axis, have a possible error of about 0.3 percent. Such a great uncertainty would affect any calculation of the trajectory of a moon rocket, since calculations must take into account the moon's mass. It is therefore desirable that one of the early moon experiments be devoted to a more precise measurement of this quantity.

There are two possible ways of doing this. The best way is to track the rocket as it approaches the moon, and to deduce from the path which the rocket takes, and from its instant of arrival, the force of the moon's pull at each point. This is entirely practical in principle, but it requires considerable accuracy in the tracking. The accuracy requirements almost certainly could not be met by an electronic tracking system on the earth. A radar altimeter and doppler drift measurement from the lunar vehicle itself might provide sufficient accuracy for such a determination. The use of ballistic cameras which could position a large diffuse reflector or a flashing light on the vehicle against the star background is also a promising possibility for accurately determining the motion of a vehicle relative to the moon.

An alternative method would measure the lunar gravity from the surface of the moon directly, after the rocket had landed. This kind of measurement is relatively simple, and can be performed by measuring the displacement of a known mass suspended from a carefully calibrated spring, by measuring the time-of-fall of a body in a known distance, by measuring the period of swing of a pendulum of known length, etc. Any one of these techniques is capable of measuring the gravity of the moon with an error considerably less than one part in a thousand.

A measurement of the lunar gravity at some point on the surface is not sufficient to determine the lunar mass, however. The other parameter is the square of the distance between the measuring point and the moon's center. The average radius of the moon is about 1,740

km. Some of the mountains of the moon have been determined to be more than 1.3 km. high. There are escarpments over a kilometer high separating plateaus from low lying plains or maria, and the crater bottoms are at a different level from the surrounding land. In fact, the variations between various parts of the moon's surface, since the so-called "continental" or "sea" areas are at different heights above the mean level, makes a determination of the size and shape of the moon somewhat uncertain. According to Baldwin, the lunar bulge is 2200 m. (in the direction of the earth), and the uncertainty in this quantity is about $\pm$ 200 m. This alone corresponds to a possible error in height above the moon's center of 1/10,000, and a corresponding error in the lunar mass determination of 0.02 percent. It would appear, therefore, that this may be the limiting factor in determining the lunar mass from an observation of lunar gravity on the moon's surface, but it would still reduce the present uncertainty by an order of magnitude.

(*b*) *Direct measurement of the lunar magnetic field.*—At present there is apparently no evidence at all that the moon has a magnetic field It must have one, however, since it could hardly have existed for so long in close proximity to the earth without experiencing some effect of the geomagnetic field. Furthermore, the lunar magnetic field would depend on the method of formation of the moon and on the magnetic field in which it existed during its formation.

If we consider that an approximate lower bound to the lunar magnetic field is the strength of the earth's magnetic field at a distance of 386,000 km., then we would be faced with measuring a field of about 0.14 gammas. (The magnetic field at the surface of the earth is about 0.5 gauss, or 50,000 gammas.) Familiar techniques exist for measuring magnetic fields down to a few gammas, but this remnant of the earth's field may, by itself, be too small to measure. Thus, the first such magnetic field measurement should be considered as exploratory, with as much sensitivity as possible.

It may be that the moon's field is much stronger than this, due, perhaps, to internal circulations while it was cooling, or it may be that the moon's magnetic field does not align itself with the extension of the earth's field. If either of these possibilities is true, it would be of considerable theoretical interest, since it might reveal something about the way in which the moon was formed and about the history of the earth-moon system.

Another likely cause of a lunar magnetic field larger than the one just calculated would be the retention of the larger magnetic field in which the moon was embedded at the time of solidification. It has been held that the moon was closer to the earth when it solidified, and so may have been in a stronger field at this time.

(*c*) *Mass spectrographic measurements of the lunar atmosphere.*—It is customary to think of the moon as having no atmosphere at all Astronomical observations have given no sure indication of a lunar atmosphere. Theoretical calculations on the persistence of any remnant of an atmosphere show that even the heavier gases, such as krypton, xenon, and perhaps CO_2, would slowly escape from the hot sunlit side of the moon.

Nevertheless, there is a possibility that enough gas is trapped in the crust of the moon so that there is a steady leakage of this gas. The heavier gases would stay on the surface for a while, so there would

be a very tenuous but constantly replenished atmosphere. A measurement of the constituents of this atmosphere would reveal information about the rate at which these gases were being released by the crust. This would be of considerable help in understanding the constitution of the crust and the way in which the moon was formed.

It is possible to design a lightweight mass spectrograph which could give an indication of both the atmosphere density and the atomic mass distribution of the lunar atmosphere—or at least an estimate of an upper bound of the amount of each gas present. The University of Michigan has proposed a design for such a gas analyzer, working on the principle of an "omegatron," which could possibly be used in a satellite vehicle and which would operate down to pressures of the order of 10^{-10} mm.Hg. If it could function in a satellite, then it should be able to function on the moon. There does not seem to be any sure way at this time of estimating whether this lower limit in pressure will be enough to detect the trace of a lunar atmosphere, but the experiment certainly warrants a try (perhaps preceded by the observation of pressure described in (d)).

(*d*) *Pressure and density of the lunar atmosphere.*—A measurement of the pressure or density of the lunar atmosphere alone would not be useful as a measure of the individual constituents, as suggested in the previous section. Its only advantage would be in the fact that a pressure measurement is simpler, in principle, than a mass spectrographic measurement. If weight or complexity were a problem, then it might be desirable to make a pressure measurement first. Having established the existence or nonexistence of a measurable atmosphere, the decision to operate a mass spectrograph could be made on a firmer basis.

(*e*) *Seismic and microseismic observations of the lunar crust.*—There are probably two natural sources of motion in the moon's crust: those caused by shifting, sliding, or folding of the crust; those caused by the impact of meteoroids.

In order for the first to occur, the middle of the moon would have to be plastic or molten, as in the case of the earth, since it is hard to imagine much shifting of the moon's crust if the moon were a rigid sphere. Occasionally there might be a landslide due to small-scale fracturing of a cliff subjected to the large monthly temperature variations, but a landslide would probably not register as a "moonquake." It is an open question as to whether the moon has a molten interior. In the geologic past there seems to have been volcanic activity, and the maria appear to have been laid down as a covering of molten material. However, since man has been observing the moon there has been no clear case of an active volcano on the moon, and so it may be completely solidified by now. Listening for moonquakes would be one way to find the answer to this riddle.

There is, however, no doubt about the fact that meteoroids are continually impacting on the moon. Most of the particles from interplanetary space are very small, with diameters of less than a millimeter. These would have almost no effect on the moon's surface during our period of observation and would not cause any measurable microseisms. However, there is a definite possibility that several large particles might hit somewhere on the moon during the period of observation. Depending on their energies and their distances from the instrument, the impacts would be detected as waves in the crust,

just as the impulse from explosions on the earth's surface is picked up hundreds of miles away. In the case of the moon there does not seem to be any way of determining how far away a meteoroid hit, but it might be possible to get some useful information from the character of the pulse.

If an explosion (or explosions) could be created at a known time and at a place some distance from the recorder, then one could make full use of the powerful techniques which have been developed for seismic prospecting. For studies of the lunar subsurface and core, this would certainly be preferable to depending on meteor impacts. In order to use seismic prospecting techniques, one must know the distance between the explosion and the recorder, and the recorder must be able to measure the time of travel, and the character, of the shock wave. Actually, after traveling a short distance in the lunar crust the original shock wave would be broken up into a number of waves with different group velocities and modes of propagation, and the analysis would depend to a large extent on being able to sort out the various components of the wave. This would mean that the wave would have to be recorded with considerable time resolution, and the record would then be transmitted to the earth by a playback mechanism. This would allow one to expand the time scale of the record in order to accommodate the band width of the telemetering link.

The source of the shock used in the seismic experiment, which must be at some distance from the detecting instrument, could be an HE or atomic explosion, or, possibly, the impacting of another part of the vehicle system. For example, if a last stage similar to the Vanguard second stage were used to start the instrumental section on its way, weighing about 800 pounds empty, it would release an amount of energy on impact with the moon (at 9,000 foot-seconds) equivalent to nearly the same number of pounds of TNT. Naturally, the instrument package would have to precede it and land before the impact of the booster occurred, but this would require only a small extra push to the package early in the flight.

A more elaborate experiment can be conceived, in which grenades could be ejected from the moon rocket, could travel a known distance, and then explode on hitting the ground. This would give a pulse of known energy at a known distance from the seismograph. If this experiment were considered crucial enough, it could probably be performed, but the weight of the auxiliary projectiles, the accuracy with which they could be aimed, the effects of rough terrain, and other problems make such an undertaking seem rather difficult.

(*f*) *Observations at the point of impact.*—As mentioned earlier, the most valuable experiments, at least in the initial stages of lunar exploration, are those which deal with the moon as a whole. However, it is clear that there are a number of things concerning the surface on which the package landed which would be of great interest. Among the important properties which would lend themselves to measurements are:

(i) Temperatures of the surface and subsurface.
(ii) Surface hardness.
(iii) Chemical composition of the surface material.

A Soviet suggestion for the use of mobile instrument carriers equipped with television links to the earth (called "tankette labora-

tories") is an interesting way of extending such local observations over a wider area.

7. PLANETARY AND INTERPLANETARY INVESTIGATIONS

The requirements for landing an instrument package gently onto the surface of the moon are roughly equivalent in difficulty to those for placing the same weight of instruments on a collision course with either Mars or Venus. The detailed problems to be solved are different, particularly with respect to guidance, but the propulsion requirements may actually be considerably less for the interplanetary flight. It should be noted that the velocity necessary to escape from the earth-moon system is less than 0.01 percent greater than the initial velocity required to just reach the moon.

The achievement of a heliocentric orbit is in many respects easier than an interplanetary (i. e. planet-to-planet) trajectory, since the propulsion requirements are about the same while the guidance accuracy required would probably be less, depending on what is expected of the orbit. For this reason, it is not unreasonable to treat interplanetary and heliocentric flights together, even though the scientific objectives may be quite different.

One of the major problems in unmanned interplanetary flight will be that of communications and tracking. For example, at the distance of Mars at closest approach (about 50,000,000 miles on the average), it would require an astronomical telescope with a 20-inch aperture to see a one kilometer diameter sphere with an albedo of one (a white surface). This suggests that very large inflatable balloons or corner reflectors will have to be used if the space vehicle is to be tracked optically, or it will have to carry a bright source of light on it. Tracking by radar is not out of the question, though powerful transponders would be required to allow it to be reached at such a range.

Communication over these great distances will obviously require a great deal of transmitted power. All other things being equal, the power required increases with the square of the range of the communications link. For example, it is claimed that an advanced narrow band width (an effective predetection noise band width of 10 cycles per second) telemetering system called the microlock system can now be designed to reach 3,000 miles with only 1 milliwatt of transmitted power. At the mean distance of Mars at closest approach the power required for such a system would be about 200 kw. There are undoubtedly other schemes which are better suited for this, but the problem certainly requires attention.

Some of the scientific objectives of interplanetary flight, objectives which can only be attained by such an effort, are listed below. An attempt has been made to name the simpler experiments first, and it appears that these simpler ones would in every case yield information required for the planning of the succeeding flights.

(a) *Determination of the astronomical unit.*—The basic unit of length used in astronomy is the semimajor axis of the earth's orbit about the sun (the astronomical unit or a. u.), now estimated to be 92,900,000 miles or 149,600,000 km. and known only to three or, at most, four significant figures. It is taken as the basic unit because the diameter of the earth's orbit is the longest baseline which terrestrial astronomers can ever achieve. The parsec, a derived unit of length which is

commonly used to measure stellar distances, is the distance at which the astronomical unit subtends one second of arc. In order to relate the a. u. to our usual yardsticks, it is necessary to triangulate from the earth on interplanetary objects whose orbits can be observed and timed. The closest objects of this kind are the asteroids, but the closest asteroids are several million miles away, and so triangulation from a baseline on the earth on such an object cannot be done with great accuracy (as evinced by the uncertainties in the above quotation of the a. u.).

The situation would be greatly improved if astronomers were provided with an "artificial asteroid," one which passed relatively close to the earth occasionally and which could be observed as it circles around the sun. Ways of making it observable will require further thought, as will the corrections which may have to be applied for solar radiation pressure, meteoric and coronal drag, the perturbations of the earth and planets, etc. By the time this experiment is achieved there will probably be enough information available on interplanetary conditions to permit such corrections to be made quite precisely.

An improved value of the a. u. would reflect itself in improved precision in other fundamental constants. For example, the constant of gravitation expressed in terms of the a. u., the solar mass, and the mean solar day, is known from astronomical observations to nine significant figures; the gravitational constant expressed in c. g. s. units is known from laboratory measurements to only four significant figures. It is the low accuracy in the conversion factors between the two sets of units, especially the unit of length (a. u. to c. g. s.), which prevents a conversion of the more precise value of this fundamental constant to the c. g. s. system.

(*b*) *Determination of planetary masses.*—Having established the distances between objects in the solar system more accurately, the next objective in astronautics would be the determination of the masses of these objects. It is necessary to know the mass of a planet in order to determine its effects on the path of a nearby space vehicle, so planetary masses will be an essential input in calculating interplanetary trajectories accurately.

It is just this relationship between planetary masses and trajectories which forms a useful basis for a mass determination. Space vehicles dispatched on paths close to the various planets would be accurately tracked (perhaps with auxiliary position sensors in the vehicles themselves such as star trackers and radars). From a precise trajectory, the planetary mass would be deduced.

(*c*) *Entry into planetary atmospheres.*—As noted above in connection with advanced satellite experiments, section 5 (d), it will be possible to learn a good deal about the planets and their atmospheres from satellite observing stations. However, a logical prelude to actually landing on a planet (though probably not a necessity for Mars or Venus) would be the observation of the behavior of an instrumented "reentry body" as it plunged into the planet's atmosphere. From a knowledge of its approach trajectory and a time history of altitude, deceleration, and vehicle surface heating, the atmospheric data necessary to design subsequent entry vehicles could probably be determined.

Of course, the planets differ tremendously. Present estimates indicate that the penetration of the atmospheres of Mars or Venus, given a slanting approach, would be even easier than for a satellite returning to Earth. The atmosphere of Mercury is essentially nonexistent. It is for the larger outer planets that such atmospheric entry bodies or probes would be most useful. This is discussed further in the next section.

(*d*) *Landing on the planets.*—Clearly, each planet is unique in its characteristics, and so the objectives and techniques for a landing vehicle on each planet would be different. Mercury, small and sun scorched, poses many of the same problems as our moon. Venus and Mars, the most intriguing planets as well as the closest, will undoubtedly merit attention first, and the problems associated with placing instruments on their surfaces are so similar to placing instruments on our earth's surface that development of landing schemes and experiments should be fairly straightforward, once the guidance and propulsion problems have been overcome. The large outer planets are entirely different from the inner planets, and there may be no such thing as "landing" on their inner cores, which very possibly are nowhere solid but may consist of a liquid center merging with a deep gaseous envelope. One might, instead, design a vehicle which would enter the atmosphere of such a planet and then settle to a certain density level where it would float, like an inextensible balloon. As for Pluto, we can now only guess at what its atmosphere and surface are like.

Restricting the discussion to Venus and Mars, the significance of obtaining observations on the surfaces of these two planets is too obvious to require emphasis. Moreover, the number of things which one would wish to find out about these sister planets is overwhelming. The most compelling question is, undoubtedly: What forms of life, if any, do they have?

For the purpose of paving the way for subsequent landings on these two planets by manned spaceships, the following are probably the most important features to be determined:

(i) Atmospheric density and composition near the surface.

(ii) The range of atmospheric temperatures and winds near the surface.

(iii) Gross terrain features, such as mountains, valleys, snowfields, and, at least in the case of Venus, possible rivers and seas. It must be remembered that the surface of Venus is unobservable in the visible or infrared due to the continuous cloud deck, so one must both land to explore its surface, and fly over it at relatively low altitude to map it by radar. Mars could probably be roughly mapped by serial reconnaissance without having to penetrate its atmosphere, but it might be impossible to identify some features without a closer look.

(iv) Surface composition. One would expect the surfaces of these planets to be infinitely varied, as is the surface of the Earth. Still, one would learn a great deal about the conditions to be encountered on landing if one had previous knowledge of the chemical composition of some representative soils, their hardness and depth, their moisture content, etc.

8. MANNED SPACE FLIGHT

Although it is impossible to predict how quickly man himself will follow his exploring instruments into outer space, the inevitable culmination of his efforts will be manned space flight and his landing on the nearer planets. It is clear that he can develop the ability to do this, and it is hard to conceive of mankind stopping short when such a tempting goal is within reach.

The attainment of manned space flight, however, cannot now be very clearly justified on purely rational grounds. It is possible, at least in principle, to design equipment which will do all the sensing needed to explore space and the planets. Mobile vehicles could be designed to land and crawl across the face of each of these distant worlds, measuring, touching, looking, listening, and reporting back to earth all the impressions gained. They could be remotely controlled, and so could act like hands, eyes, and ears for the operator on earth. Moreover, such robots could be abandoned without a qualm when they ran out of fuel or broke down.

Though all this could be done in principle, there may be a point at which the complexity of the machine to do the job becomes intolerable, and a man is found to be more efficient, more reliable, and, above all, more resourceful when unexpected obstacles arise. It is, in a sense, an article of faith that man will indeed be required to do the job of cosmic exploration personally and, furthermore, that he will want to do the job himself, whether required to or not.

With man's first venture into outer space a new program of research and exploration will begin. The program described above will, therefore, be the prelude to the drama to follow.

Mr. McCormack. According to the understanding, we are very glad to have with us another distinguished gentleman. We are glad to have you with us.

Dr. William H. Pickering, director of the Jet Propulsion Laboratory of the California Institute of Technology.

Dr. Pickering?

Dr. Pickering. Thank you, Mr. Chairman.

Mr. McCormack. We have the biography of both of you gentlemen. And without objection we will see that the staff puts that in the record preceding your testimony.

Dr. Pickering. Thank you.

STATEMENT OF DR. W. H. PICKERING,[21] DIRECTOR, JET PROPULSION LABORATORY, CALIFORNIA INSTITUTE OF TECHNOLOGY, PASADENA, CALIF.

Dr. Pickering. Mr. Chairman, in recent months it has become obvious to all of us that the scientific and technological leadership of our country has been challenged by the dynamic growth of science and technology in the U. S. S. R.

---

[21] Pickering, Prof. W(illiam) H(ayward), California Institute of Technology, Pasadena 5, Calif. Electrical engineering. Wellington, N. Z., Dec. 24, 10, nat. 41; m. 32; c. 2. B. S., Calif. Inst. Tech., 32, M. S., 33, Coffin fellow, 33–35, Ph. D. (physics), 36. Asst. and teaching fellow physics, Calif. Inst. Tech, 32–36, instr, 36–40, asst. prof. elec. eng, 40–45, assoc. prof. 45–47, prof, 47 —, div. chief Jet Propulsion Lab, 52–54, Director, 54– Lecturer, Southern California, 38. Civilian with Research Develop. Board; A. F, U. S. N., U. S. A, 44. Inst. Elec. Eng; sr. mem. inst. Radio Eng. Cosmic rays; telemetering from balloons and rockets; microwave propagation; development of cosmic ray radio sonde; missile guidance problems.

The sputniks were a remarkable achievement, but these are only the last in a long list of triumphs in both military and civilian technology that the U. S. S. R. has shown to the world in the last decade.

Viewed against the background of a nation which was only recently one of the most backward of the major powers, this is even more remarkable. It therefore behooves us to either accept second-class status or demonstrate to all the worldt hat we are capable of an even more dynamic development.

The area of space science is only a part of the complete scientific picture, and although it has had a most dramatic impac ton the people of the world, it is essential that we do not become so obsessed with this activity that we neglect other areas of scientific endeavor.

Like the atomic energy field, space technology will reach into many parts of science and will contribute technical advances in quite unexpected areas. Therefore, support of space science will nurture much other scientific achievement, but it will not be a substitute for a broad program of basic scientific support.

The really important future scientific breakthroughs may come in completely unexpected fields, and only if basic research in these fields is adequately supported can these achievements become American and not Russian achievements.

Space technology is obviously of interest both to the scientists and military men. In my opinion, the scientific interest should come first. Only in this way can we be assured of a technically sound and complete exploration of the potentials of space.

I will expect that military applications would follow quickly upon the completion of scientific objectives. This pattern has been followed for many years. The experience of World War II demonstrated how scientific work could be quickly transferred from the laboratory to the battlefield. Since World War II the support which the military departments have given to basic scientific studies in the universities and elsewhere has been an indication of the appreciation of the military for the contribution of basic scientific work to military technology.

The exploration of space will follow a pattern which has been exemplified by the exploration of the upper atmosphere. Instruments are now being used to explore the properties of the upper atmosphere at altitudes far beyond those attained by manned vehicles.

I might note that since World War II rockets of various sorts have been used for this purpose and a continuing program of upper atmosphere exploration has been carried on in this country and elsewhere. This has led to a tremendous amount of scientific information about the properties of the upper atmosphere up to perhaps a hundred miles above the surface of the earth.

Similar types of instruments will be used to extend our knowledge far beyond the earth out into space and eventually to the moon and to the planets. Manned vehicles will be expected to come along later, after our experience with instrumented vehicles has shown the problems to be encountered and solved before man can safely venture out into space.

In conducting this instrumented exploration many new and unexpected phenomena may be encountered. It is only when we have a thorough understanding of these phenomena that we can properly utilize space for military or commercial applications or for manned vehicles.

The exploration of space even with instrumented vehicles is very costly. It is therefore essential that a well-planned national program be established. Such a program must be coordinated with the scientific community; it must be imaginative but not extreme; it must be actively pursued in order to maintain our national stature; and it must be funded on a long-term basis, because of the long lead time in most of the objects with which this would be dealing.

Likewise the program must receive active support from the military services because of the guided-missile technology which obviously must be used to initiate the work.

In view of the magnitude of the effort which is estimated to become comparable with the AEC expenditures, it appears that a national space agency is required. The proposal contained in the President's message of April 2 appears to embody most of these objectives.

This proposal appears to build a new NASA on a nucleus of the present NACA. However, it is clear that the charter of the new agency differs in kind as well as in magnitude from that of the NACA. As stated by Dr. H. Dryden to your committee on April 16—

> Over the years, NACA has interpreted its charter to mean that its primary task was to provide the aircraft industry and the military services with information and technical data of a fundamental nature that would assist them in constantly improving military and civilian aircraft and missiles.

The proposed new agency is charged with, as stated in section 6A:

> (1) Develop a comprehensive program of research in the aeronautical and space sciences;
>
> (2) Plan, direct, and conduct scientific studies and investigations of the problems of manned or unmanned flight within or outside the earth's atmosphere with a view to their practical solution;
>
> (3) Develop, test, launch, and operate aeronautical and space vehicles,
>
> (4) Arrange for participation by the scientific community in planning scientific measurements and observations to be made through use of aeronautical and space vehicles, and conduct or arrange for the conduct of such measurements and observations; and provide as appropriate for dissemination of data collected; and
>
> (5) Submit to the President for transmittal to the Congress an annual report of operations and accomplishments.

I am particularly interested in items (3) and (4) which I believe represent a significantly different approach than the present NACA approach to aeronautical problems. Here the new agency is given responsibility for a complete space-vehicle program including the scientific mission.

Thus the present NACA will find that the new agency becomes one of its best customers, and only in this sense is the NACA really a nucleus for the NASA.

The present NACA has proved to be of tremendous value to the whole aircraft industry—both civilian and military, and it appears to me that it should continue to act in this capacity not only for the aircraft industry but also for the new space-vehicle programs of both civilian and military groups.

The NASA would then conduct its space experiments with a new administrative organization which would probably have much of its work done by contract, while the NACA part of the organization would continue to provide essential basic engineering and scientific information.

I believe that if the new Agency can be established with the systems responsibility indicated by section 6A, paragraphs (3) and (4), that

this will indeed be the proper approach to solving the civilian space problems of the Nation.

Those of us who have been associated with the rocket and guided missile art for the past decade are well aware of the necessity for proper systems integration in programs of this complexity. Perhaps some day a space vehicle will become just another truck to carry a payload out into space or to some distant planet, but that day is a long way off and for now we must appreciate the fact that all space experiments will be conducted as research-type activities in which the success of the mission will depend largely upon the care with which the complete system for the experiment has been designed.

In conclusion, I can only stress my belief that it is urgent for the national space program to be established on a firm, continuing basis. We are already behind Russia in this area and unless we move energetically into a program which is on a sound scientific basis, we will continue to be second to the Russians.

The CHAIRMAN. In connection with any questions asked by the members of the committee, gentlemen, you may interchange in making your answers.

You have both read the bill, have you not?

Dr. DUBRIDGE. Yes, sir.

Dr. PICKERING. Yes, sir.

The CHAIRMAN. Do you think the bill contains the language which would emphasize the civilian side more strongly?

Dr. DUBRIDGE. Yes.

The CHAIRMAN. We all recognize, of course, the necessity for this and its military applications.

Dr. DUBRIDGE. Yes.

I think we both stress the fact that there are important military applications. I am assuming the Defense Department will continue in the future under whatever organization is created to continue the military space research necessary for purely military objectives.

But there are many objectives in space research that do not have obvious or direct military application and importance. Therefore, an additional agency is needed for that.

The CHAIRMAN. Have you any particular views as to the kind of organization that should be set up, which might be different from the form or nature of an agency as outlined in the bill?

Dr. DUBRIDGE. I think that, in many respects, the bill creates a very good pattern. My only reservation in regard to the bill is that it creates the impression—though I think, if you examine it, as Dr. Pickering has pointed out, you will find that this impression was not accurate—the bill creates the impression that the new agency is only a slightly enlarged NACA.

But, as a matter of fact, it differs from NACA and, in real content, it is really a new agency of which NACA will now become a part and only one part. And I think that this illusion, that the bill expands NACA without doing anything else, has created some misunderstanding, and I think some of the discussion this morning was based upon this misunderstanding that the NASA, as proposed in this bill, is only a slight elaboration of NACA.

It is different from NACA in at least two respects. First, this becomes not just a research agency, but a widespread—well, I do not like to use the term "operating" because the term "operation"

has some misunderstanding, as we discovered. But it has a widespread authority in directing and stimulating and carrying out programs of space exploration whereas the NACA is largely a laboratory research agency.

And, secondly, the relation between the Director and the Board in the new bill is essentially different from the relation between the Director and Board under present NACA in this respect: Under the NACA, established many years ago, the Board is the responsible agency. It is kind of like the board of directors of a corporation. It is the responsible, policymaking agency.

It selects the Director and then delegates to the Director the responsibility for selecting the staff and carrying out the program under the policies established by the Board. But the NASA, as I understand it, has the Director of the Agency, who is the responsible person, responsible directly to the President, and the Board that is created is more of an advisory commission or an advisory board advising the Director.

In other words, the NACA follows one pattern; the NASA follows a pattern more like that of the National Science Foundation. And the more recent tendency in Government has been to follow the National Science Foundation plan rather than the NACA plan.

And this NASA is more like the National Science Foundation scheme; namely, a director appointed by and responsible to the President, and a board whose function is really advisory.

The Director is morally bound, I am sure, to follow the policies which the Board recommends and formulates and yet, in principle, the Director is responsible to the President directly, not through the Board to the President.

Now, this is an important distinction. And I am not saying at the moment which of these two philosophies is correct. But they are different.

Therefore, I think it is a mistake to assume that NASA is only an expansion of NACA. I am glad that this is the case, because I think the job to be done by NASA is, in substance and in content and in kind, different from the job that NACA has had.

I would like to think of this as a brandnew organization, created to do a brandnew job, a very extensive and a very important job, of which the old NACA job is just one part.

The CHAIRMAN. Dr. Pickering, you referred in your statement to five of the basic conditions that the new Agency will be charged with and have jurisdiction over. They were to develop, test, launch, and operate astronautical and space vehicles? Isn't that pretty broad language?

Dr. PICKERING. Yes.

The CHAIRMAN. Does that carry the power for this Agency to make contracts with others in the exploration and in the operational angle?

Dr. PICKERING. That is right. In order to carry out this assignment, it must have all of these other powers. And, as far as I am concerned, this centralization of the powers in this Agency, I believe, is correct.

The CHAIRMAN. Do you think the two agencies of Government should have the same power as Dr. Furnas indicated?

Dr. PICKERING. I believe that the NASA should have this power, because I think, largely because the problems of carrying out this kind of a program involve the utilization of a very large test equipment, if you want to say it that way. In other words, very large test missiles of various sorts. And it involves various expensive test programs. Therefore, it only makes sense if you have a real, coordinated program under one agency directing it.

The CHAIRMAN. From that angle, there would be no necessity of creating another agency if one agency of government already had the jurisdiction?

Dr. PICKERING. No. I say NASA is that agency. I do not believe any agency now has the authority to do this.

The CHAIRMAN. Well, Dr. Furnas seemed to indicate——

Dr. PICKERING. We disagree.

The CHAIRMAN. That he favored, also, the National Science Foundation through its contract powers. You would not agree with that, would you? Well, I do not want you to pass on somebody else's testimony.

What are your views on that?

Dr. DUBRIDGE. If I may put in one word; the first part of the questioning this morning revolved around the misunderstanding of what you mean by "operating." Now, if I may explain what I mean by "operating," the National Science Foundation is not an operating agency. It does not operate its own laboratories. It contracts for all of these operations. The Atomic Energy Commission is not an operating agency. It contracts for all of its activities, for its research, for its development, for its manufacturing, and everything else.

The CHAIRMAN. But, through the contracts, it is an operating agency?

Dr. DUBRIDGE. It controls, but it does not operate.

The CHAIRMAN. I know, but——

Dr. DUBRIDGE. You see, there is the point of distinction between what you mean by "operating" and "not operating."

Mr. MCDONOUGH. But it does specify?

Dr. DUBRIDGE. The NACA is an operating agency. It operates its own laboratories. It does not contract for them at all. They are Government laboratories; they are Government controlled and paid for; and civil-service regulations apply to the employees, and so on.

In a sense, NACA is an operating agency in a sense that it operates its own functions while NASA is not because it contracts. That is one sense of the word "operating." Another sense or meaning of the word "operating" means to go out in the field and do big experiments, as contrasted with staying in the laboratory and doing research. That is a different flavor to the word "operating."

I think one must be careful as to what you mean. Usually, in Government, it is my experience that "operating" refers to the direct control and operation under Government auspices and with Government employees of a particular activity as contrasted to contracting for that activity with a private industrial or nonprofit organization.

Now, in that sense, NACA is an operating organization. The new NASA will have both operations and contracts, because, presumably, the NACA laboratories will continue as at present, but it also has the power to contract for new activities as well as to operate new activities, so, I am just bringing this out to show a possible confusion that the word "operating" may bring out.

The CHAIRMAN. Well, the thought I have in mind is that, in this field of outer space, we refer to that for descriptive purposes. Should two agencies have the same powers and same jurisdiction?

Dr. DUBRIDGE. No.

The CHAIRMAN. And it belongs with the new Agency, if one is established?

Dr. DUBRIDGE. Yes.

The CHAIRMAN. Now, projecting your mind into the future, can you see whether this new Agency will—where these discoveries that you know can be put into practical operation, the ones you know now, and what may flow, say, from the peaceful purposes; can you see the new Agency having regulatory powers?

Dr. DUBRIDGE. Again, it depends upon the definition of the word "regulatory." A regulatory agency, like a public-service commission, is regulating the activities of a lot of private, independent corporations and activities serving the public, no doubt. But still thay are private, independent, self-sufficient, and self-capitalized activities or corporations. And the Government regulates their activities for the public good.

Now, in this field I do not at the moment see a lot of private organizations shooting rockets to the moon, or doing other things that have to do with real space exploration except as they do this under a contract with this new agency.

In other words, it is not an activity that is going to give itself over to great private enterprise and therefore regulation of private enterprise in the sense of a public service commission will not be necessary.

But I do think, on the other hand, that it is very important that the United States Government have control of the activities which go on in the United States in the space field and not every Tom, Dick, and Harry should be allowed to shoot rockets off into space.

The CHAIRMAN. That involves regulatory power?

Dr. DUBRIDGE. Yes.

The CHAIRMAN. Furthermore, we know the setup of the AEC, and, of course, under the law any individual or any corporation or any group who makes a new discovery which is in no way connected with Government funds or entitled to the benefit of that—as I remember it, if they applied for a patent, the Atomic Energy Commission must be notified and if the Atomic Energy Commission considers that to be in the national interest in connection with our defense, they can stop a patent being issued; they can take it over; they compensate the individual or group, because the national interest is involved.

So that the AEC does have either direct or indirect control over all new discoveries, even those made purely in the private field.

Dr. DUBRIDGE. That is correct.

The CHAIRMAN. And there are other methods of control also.

That is what I had in mind when I was asking some questions of Dr. Furnas. I am sure that if he had in mind what I did, he might recognize we just cannot have people, corporations, or others, having great secrets where the national interest of our country is involved to the exclusion of the Government. And that involves some degree of regulatory power; is that correct?

Dr. DUBRIDGE. Yes.

The CHAIRMAN. Furthermore, if a corporation makes a discovery which is not considered in the national interest where under law we

25973—58——52

step in and compensate and take over, or they can provide that it be made classified, the details of the new discovery, even if the Government does not take it over, can be classified. That is regulatory power. That might exist in this agency.

Is that correct, Doctor?

Dr. DuBridge. I assume it would be correct if it was judged that the new discovery or invention had military security importance.

The Chairman. Yes. I said in connection with the national interest.

Dr. DuBridge. Yes.

The Chairman. And even if a corporation made a discovery which was not considered such and the Government makes a contract with another company on some end product, the Government can use that discovery, let the new company, the second company, use it, although they have got to compensate the first company.

Dr. DuBridge. The AEC can, yes.

The Chairman. One can see there has to be some degree of regulatory power. And as these discoveries become more and more practical they might increase?

Dr. DuBridge. If instead of using the word "regulatory" we use the word "control" or "direction," it becomes I think, clear that we want to give direction to our space program and that a single agency must give direction.

It must do it through the mechanism of regulation.

The Chairman. Mr. Hays?

Mr. Hays. I have no questions, Mr. Chairman.

The Chairman. Mr. Metcalf.

Mr. Metcalf. I would like to——

The Chairman. Oh, pardon me, Mr. Metcalf, for just a moment.

Doctor, I notice your interest is on the civil side in connection with space activities. Would you look this bill over, and if you have any suggestions to make as to your views in which you think the committee might strengthen it, would you submit that, please?

Dr. DuBridge. Yes.

Mr. Metcalf. Just so that I may understand your ideas of how this is to be organized:

In addition to this operational use in two senses, that is, actual laboratory experimentation, and contracting, there has to be some directional authority, does there not, in any agency?

Dr. DuBridge. Yes.

Mr. Metcalf. It seems to me that we were talking about the Weather Bureau this morning. Now, this new space has very important connotations for weather.

But the direction has to be in the new Space Agency rather than in the Weather Bureau.

Dr. DuBridge. I would think so, yes, sir.

Dr. Pickering. I would like to comment on that.

The new Space Agency, as I see it, is going to have to work with a variety of different agencies, universities, scientific groups of various sorts.

Mr. Metcalf. Private business organizations?

Dr. Pickering. Yes.

To bring the whole picture together, yes.

Dr. DuBridge. The National Science Foundation and the military.

Dr Pickering. Yes.

Mr. METCALF. In fact, at some time or other, maybe all the branches of the Government—maybe, for instance, the Forest Service may want to have something to watch out for fires instead of having another system; but they could not launch a satellite.

So, they would go to the National Space Agency, which would have the directional authority and control and maybe employ the Weather Bureau to carry out the research?

Dr. DUBRIDGE. Yes.

Yes, I think that you have expressed exactly the thought that I was trying to express as to the function of this Agency, to direct, control, and coordinate.

Mr. METCALF. I marked one question here.

You said that we must be both bold and careful. And in carrying out that task we have to have initially the best organization; would you not agree?

Dr. DUBRIDGE. Yes, sir.

Mr. METCALF. Now, then, it is all very well to say that the NACA has done a good research job since 1915, or to point out that the Atomic Energy Commission has worked well in handling that nuclear development; but when you testified you said you did not want to compare the difference between having a director over a board and a board over a director.

What, in your opinion, is the best organization here?

Dr. DUBRIDGE. Personally I would prefer an organization here similar to the NACA organization. That is, the Government appoints a board of directors and gives that board authority to employ a president, a director, and then to have that director responsible to the board.

And then all things would flow from there. In other words, have your line of authority from the president to the board of trustees, to the director, and then out to the staff and the operations.

The CHAIRMAN. Why not a commission instead of a board?

Dr. DUBRIDGE. Well, then you have 5 bosses instead of 1.

I prefer a single director and not five directors. A commission means five full-time people. So you have five full-time bosses.

A board of directors or trustees is a normal American free enterprise tradition. We know how to operate with boards of directors.

The CHAIRMAN. The Government is not based on the corporate system.

Dr. DUBRIDGE. Yes.

But you asked me what my preference was.

The CHAIRMAN. I understand.

Dr. DUBRIDGE. My preference is to use the American system, a board of trustees or a board of directors. All of our universities and corporations operate on this basis.

It sets policy and direction and is responsible for the appointment of a director. And he carries out these things.

The CHAIRMAN. I do not want to see the day that they would act as a unit.

Dr. DUBRIDGE. Their final vote is a vote of a body. But when you have a commission, then you have five different people sharing responsibility, and I think this is bad organization.

The CHAIRMAN. Do you think the AEC would be better off if it had a board of directors and a single operator?

Dr. DuBridge. I think the AEC would be better off, yes, if it had a board of directors and a single operator.

The Chairman. A very serious question.

Dr. DuBridge. I know it is.

I say this with some hesitation. But I have watched the AEC work for 10 years.

The Chairman. According to what man is the head; is that right?

Dr. DuBridge. The man that is the head makes an enormous difference.

The Chairman. Whether he is rather dictatorially inclined or not, and all those things, you think?

Dr. DuBridge. Any organization can be wrecked by a bad man.

Another reason for a board of directors rather than a commission of full-time people is that it would be extremely—or it is extremely difficult to take the best scientists, the best industrialists, the best lawyers from private activities and bring them in as full-time Government employees.

The AEC, as you know, has got some very good people, but they have also been turned down by some awfully good people who will not leave their private practice or private business to go into the Government.

Now, this board of directors of the NASA could be comprised of the best talent in the country that nobody would turn down, being a member of this board. It would mean maybe 15 meetings a year. It would be an important job. It would not interfere with his private practice.

So, you could command the best brains of the country. I would rather have the part time of 17 of the best brains in the country than the full time of many more mediocre ones.

The Chairman. What do you think, Dr. Pickering?

Dr. Pickering. Well, my own feeling is that the divided responsibility of a commission is dangerous, is conducive to confusion, shall we say; that there should be one firm head of the agency; and one of the reasons I say this is that the agency is going to have to have a very positive program in the hardware sense. It is going to have to get out and say we will fire this on schedule and it has got to get out and make sure that its research program moves along steadily.

And this will be much easier when you have one definite head of the agency. So, I am in favor of having a definite director of the agency.

Now, whether he should report directly to the President or whether he should report to a board of 17 members I do not feel as strongly on this as Dr. DuBridge does.

Mr. Feldman. While we are on this subject and before we lose our train of thought, I would like to pursue this idea of the board of directors.

You are aware, Doctor, of course, that there are all kinds of boards of directors. And I mean by that this: I sit on some boards. I know of at least one instance in which the chairman of the board of directors, who is the principal stockholder of the company, can tell that board just exactly what to do. And if anybody disagrees with him, he does not stay on the board very long.

There are, on the other hand, boards in which there are various cliques, and the president of the company, or the director in this

instance, plays these different cliques against each other; so that the best interest of the organization sometimes is jeopardized by that fact.

So that when we talk of a board of directors on top, it is not just this harmonious thing that we are speaking of all the time, you know.

And sometimes for the good of the company there are disagreements and whatnot. So that when we speak of one versus another we have got to think of all these various shadings.

Wouldn't you agree on that?

Dr. DuBridge. Certainly.

I do not think one can guarantee that either board will be good or competent no matter which way it is set up. But I just prefer the board of directors.

But I realize that the recent trend of Government has been the other way. And I would have no violent objections if for political reasons it were decided that the NSF—the National Science Foundation—plan rather than the NACA plan were adopted.

But if you are asking my preference, I have given it.

Now, a very important aspect in either case will be the quality of people chosen by the president for the board. If the president is forced for political reasons to have somebody from every part of the country, to have somebody from each racial origin, or caste, or color, or creed, or to have so many Republicans and so many Democrats, and all the rest of it, instead of appointing the best men, then a board can be ineffective and dangerous.

Mr. Fulton. The question is: Suppose you had 5 men of different characteristics, 1 of whom might be a fine administrator, and 1 of whom might be a fine aeronautics person, and 1 of whom might be a very good propellent person, and 1 of whom might be a good astronautics or astronomer type, and we might also get somebody who had a financial brain to protect the taxpayers, wouldn't that kind of a commission setup be more rounded than trying to get somebody in this vast new field who was trying to be the czar, like the Manhattan Project that Congress moved away from, and being all things to all men, making decisions in so many fields, and so many different levels?

Dr. DuBridge. Well, I personally do not think that that would be better for the following reasons:

First, this man cannot be a czar, because the board of directors is there. Whatever capacity it is in, this board of directors is there to guide him, to set policies, to steer him on the right path.

Secondly, if you have got 5 fine people in 5 different fields, I would make 1 boss and the other 4 vice presidents and give each one operating responsibility in the field of his specialty but under the boss.

Mr. Fulton. If this director you are speaking of is confirmed by the Senate and appointed by the President, how could the board of directors then fire him or really control him?

Dr. DuBridge. Well, they couldn't under those conditions. That is why I prefer the other arrangement.

But even under this other arrangement where the director is appointed by the President and the board is more advisory, I am of the strong opinion that if the director proved to be incompetent or seeking his own self-aggrandizement at the expense of the Nation, that this board of directors would quickly spot that and would certainly report to the President, and strongly recommend that some action be taken.

Mr. FULTON. Thank you.

The CHAIRMAN. All right, Mr. Metcalf.

Mr METCALF. I want to thank both of you for forthright answers, because this is going to be a very important question.

And this conflict of opinion that is appearing before this committee is going to help us resolve this very question. And the answers you have given are beneficial and most informative.

And, of course, we would not want a harmonious board, would we, necessarily, if it is going to set policies in new areas?

Dr. DUBRIDGE. I am sure there would be disagreements no matter what kind of board you appointed.

You would expect that.

Mr. METCALF. Yes.

Now, what would be the optimum for such a board?

Dr. DUBRIDGE. That is very difficult. I would say that 5 is too few for the Board of Directors that I am talking about; but I would prefer fewer than 17.

I think 17 is a little large. I would say 9 or 11 would be better than 15 or 17 and would be better than 3 or 5.

That is my reaction.

On the other hand, I recognize that there are many fine boards around the country. The board of trustees of my own institution is a board of 30 people. They get along pretty well, and do what I think is a very fine job. So, it isn't necessary that a large board be appointed.

Mr. FORD. They made a good selection of president.

Dr. DUBRIDGE. So, I would prefer about 11 to 13.

Mr. METCALF. A board somewhere between 9 to 11, you think?

Dr. DUBRIDGE. Yes.

Mr. METCALF. Do you have any ideas on that, Dr. Pickering?

The CHAIRMAN. The doctor thinks there should be a strong director.

Mr. METCALF. But we are going to have a board in either of the systems.

Dr. PICKERING. It is an advisory board, perhaps.

The CHAIRMAN. I wanted you to clarify that.

Dr. PICKERING. I would say 20 is too many. But whether it should be closer to 10 or 17 I do not have any very strong opinion on that.

Dr DUBRIDGE. A little depends, of course, on whether you require certain representation on the Board.

Now, if you are going to require that there be a representative of the Department of Defense and the Army, Navy, and Air Force, and the National Science Foundation, and the Weather Bureau, and a half dozen other Government agencies, so you have about 11 people that are ex officio, then I think you need another 8 or 9 to do the work.

Mr. METCALF. Which brings up my next question.

Where do you think the respective areas of the military and the civilian agencies should be in this Board, and what representation should each have?

Dr. DUBRIDGE. Well, that again is a difficult question.

Mr. METCALF. You have read the bill and you know how it is divided in the bill.

Dr. DUBRIDGE. The bill, I think, says at least one shall be from the Department of Defense.

If up to 8 are from Government agencies, then obviously a total board of 11 would not be adequate.

Mr. METCALF. That is right.

Dr. DUBRIDGE. I would prefer to have 9 or 11 people chosen mostly outside of the Government and then have the Government represented through liaison offices, or ex officio liaison attachments of some sort, rather than as members of the Board itself.

But, again, this is getting into an administrative matter on which I only have slight preferences and they are not terribly strong feelings.

Mr. METCALF. Well, in your opinion—and I hope you will interrupt, Dr. Pickering, if you have any differing ideas as we go along——

The CHAIRMAN. Mr. Metcalf, would you permit me to ask this of you: Mr. Fulton has to leave on a plane at 4 o'clock. He has two questions. He wanted me to ask them. But I thought it would be better if he asks them.

Mr. METCALF. I would be glad to yield, Mr. Chairman.

Mr. FULTON. Thank you.

I have just written these two questions out as I was sitting here.

In planning an interplanetary trip to Venus, the planet closest to the sun, or to Mars, the planet farthest from the sun, does it make any difference as to the time of leaving the earth's atmosphere? For example, sunrise or sunset, midnight or high noon?

A second question is: In a trip to a planet closer to the sun than the earth, should the gravitational force of the sun be used as a practical power factor once the space vehicle leaves the earth's proximity?

Dr. PICKERING. In answering those questions, the particular time of launching for another planet is governed more by the relative positions of the earth and the planet in their journeys around the sun.

And then you choose the correct point on the earth's surface, depending on just where they are. In other words, this is tied up with what is the travel time to the other planet. During this travel, the planet is moving, and the whole problem is a fairly complicated problem. I do not think one can categorically say you should launch at sunset or noon, or anything of the sort.

Mr. FULTON. You do not try to take advantage of the earth's rotation?

Dr. PICKERING. Yes. You take advantage of the earth's rotation. And you also, of course, are flying in the sun's gravitational field and, therefore, the sun's gravitational field must be taken into effect.

For example, it is easier to go to Venus than it is to Mars, because to go to Venus you fall in toward the sun; to go to Mars, you have to climb out of the gravitational field.

Mr. FULTON. There has been some testimony here that you could take practical account of the gravitational force of the sun in our planetary system as a power or propellent.

Dr. PICKERING. It is not a propellent in the usual sense. You are moving under the influence of Newton's law.

Mr. FULTON. But it is sufficient enough to take account of?

Dr. PICKERING. Yes.

Dr. DUBRIDGE. On the other hand, you have to come against it when you come back out.

If you send something into Venus, you accelerate due to the sun's pull, but as you come back out, of course you decelerate again.

You have to work against the sun's gravity in coming back to the earth.

Mr. KEATING. It is better not to get there than to get there and not be able to come back?

Dr. DUBRIDGE. It depends upon whether there is a man aboard or not.

The CHAIRMAN. Mr. Metcalf.

Mr. METCALF. I think that it has been developed here not only through the testimony that has been presented here today but as accumulation of this testimony, that in addition to the policymaking position of the military on a board of directors or a commission or whatever they are represented on, there must be constant and continuous liaison, not only with the military but with these other operational agencies?

Dr. DUBRIDGE. That is right.

Mr. METCALF. Now, would you write that into the law, or would you make a statement in the declaration of policy for such liaison?

Dr. DUBRIDGE. I would put some provision in the law to establish a mechanism for liaison or coordination between the military agency, whatever it is, after the new reorganization and the new civilian agency, NASA.

I would write something into law to provide for that link, either joint board membership if that seems to be best, or a liaison committee such as the AEC has, or some other mechanism, I think, ought to be written in just to insure that it is the intent of the Congress that there shall be close relation between these two agencies, as there must be.

Dr. PICKERING. I would go further than that and say this program cannot succeed unless there is close cooperation between NASA and the military, because the vehicles which must be used in at least the first few years of existence of NASA must be vehicles which have been developed by the military for their own purposes.

Mr. METCALF. Would you go so far as to say that, in addition to policy liaison at a relatively high level, there has to be a day to day working liaison at a lower operational level?

Dr. DUBRIDGE. Of course.

Dr. PICKERING. I would think so.

Mr. METCALF. Both of those should be written into the law.

Dr. DUBRIDGE. I do not know how to write the second.

Mr. METCALF. The military liaison committee may be an analogy for the lower level, and then if you have a part-time board, of course you would have representatives of the Department of Defense on the policy board.

I was thinking of something along that line.

Dr. DUBRIDGE. Yes; but at the lower level—I thought you meant the working level—that means that if you have——

Mr. METCALF. Well, that would have to be worked out with the military liaison.

Dr. DUBRIDGE. The NASA, for example, is going to have some laboratory operations and plans some launchings and it is maybe going to use a Jupiter booster. And it is going to have to work with the Army Ballistic Missile Agency at Huntsville on the redesign or modification or schedule or launching and whatnot.

This will have to be a close working relationship that you cannot write into the law.

Mr. METCALF. That would have to be an administrative policy.

Dr. DUBRIDGE. Yes.

Mr. METCALF. Thank you, Mr. Chairman.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. This morning quite a bit of confusion resulted over the duties and responsibilities of the National Science Foundation.

As pointed out by Dr. DuBridge, the National Science Foundation is not an operating agency. As a member of the Committee on Appropriations—I am not a member of the Subcommittee on Independent Offices—I felt that I knew a little about the duties of the National Science Foundation and what the responsibilities were of this particular organization.

Now, this morning I almost changed my mind. Mr. Chairman, this Foundation, under its basic act of 1950 is authorized and directed to develop and encourage the pursuit of a national policy for the promotion of basic research and education in sciences.

Further, to initiate and support basic research in the mathematical, physical, and other sciences by making contracts and other arrangements for the conduct of basic science research and to appraise the impact of the research upon industrial development and upon the general welfare.

Now, the chairman of this particular subcommittee is a friend of every member on this committee. And I know the chairman will be interested in his remarks at the time the Director appeared before this particular subcommittee for its annual appropriation this year.

His statement was to this effect, Mr. Chairman:

> In other words, this Foundation operates under very broad, general language and is placed in a position of trying to lead and lead through persuasion.
>
> It does not have the authority to go out and establish a laboratory and to operate it itself. It has authority to give some money to some bright folks. The Science Foundation has the right to select these people.
>
> We do not tell you whom to pick or how to pick them. The Foundation has the authority to grant money to educational institutions for facilities.

Now, Mr. Chairman, that is the National Science Foundation. There is no conflict as to the bill before this committee and the duties and purposes of this particular Foundation.

And Dr. DuBridge, I believe, you agree with that statement; is that right?

Dr. DUBRIDGE. Yes; I do.

Mr. NATCHER. I want to thank you and Dr. Pickering for the fine statements you have made to this committee. I think both of you gentlemen understand the bill that is before the committee and the purpose of this bill and you have made fine statements and I want you to know that we appreciate it.

The CHAIRMAN. I think that is very valuable information you gave. I did not know about that. I did not think there would be this conflict or competition. If so, I do not think it should exist if we are going to establish a new agency.

Dr. DUBRIDGE. May I add one footnote to this point. I think it is quite likely then in its support of science that the National Science Foundation might be asked by some university to support a program which involves sending up a satellite for cosmic ray studies or some other scientific purposes. The National Science Foundation might be faced with a question, shall they grant so many thousand dollars to such and such a university for creating the instrument which

might be put in a satellite for scientific research. I think this is the kind of thing Dr. Furnas had in mind.

The National Science Foundation might say, "This is a good idea to give the University of Iowa a contract to create scientific instruments for a particular program of research which instruments will go in a satellite," but at this point I would say the Science Foundation would have to go to the new NASA and say, "gentlemen, we have a fine research idea here. We are willing to support it, the instrumentation which is going to be developed at the University of Iowa provided you, the NASA, will furnish the satellite vehicle to carry the instrument in some of your future flights." This is where it might be the two would come together.

Dr. PICKERING. Might I add to that? In a sense that has been the way we have operated during this past year or so in the International Geophysical Year. We have had this IGY Committee on the earth satellite program which has been under the National Academy's jurisdiction and the United States National Committee for the IGY, and this Committee then has selected scientific programs which have been suggested to it and has funded the scientific program. The actual flight testing, of course, involves the committee essentially going to the Department of Defense, in this case the Vanguard project, and saying "This is what we believe you should fly on this test," and then the Department of Defense provides the vehicles.

The CHAIRMAN. That is a question of relationship to understanding men. There will no doubt be twilight zones and we cannot legislate on every twilight zone.

Dr. PICKERING. The thing is that this is a mechanism by which a researcher in the University of Iowa, say, is able to get his instrumentation development done and to get his program put in a satellite. I visualize very much the same sort of mechanism working with the NASA.

The CHAIRMAN. Do you think the IGY should be extended, Dr. Pickering? I have heard some even mention a decade.

Dr. PICKERING. Let me start by saying that the IGY is an international effort that was planned for a certain period of time.

This involved a large international scientific effort in certain areas of science. One would like to think that the impetus of this IGY period would indeed carry on in supporting much of this scientific endeavor beyond the particular period when it was a broad international affair.

Dr. DUBRIDGE. But to continue the same type of intense and concentrated effort that IGY has involved would be a little difficult because a lot of people have left their normal pursuits and are concentrating their efforts on this particular program.

I would however hope very much that the international collaboration in science which the IGY has initiated in many fields could be continued on a reasonably permanent scale.

Mr. FORD. Is this the first IGY in the history of mankind?

Dr. DUBRIDGE. No; the third.

Mr. FORD. How far back have they gone?

Dr. PICKERING. The second was 1932. The first one was 1882. There had been an expectation that the third would be scheduled in another 50 years.

The decision was to make that 25 years because of the great advance in instrumentation and technology.

Mr. KEATING. This mean that you will go after the next one a couple of years from now.

Dr. PICKERING. I don't know. I think the amount of data we have accumulated will take 25 years to analyze.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. Dr. Pickering, you mentioned on page 3 of your statement "such a program must be coordinated with the scientific community." Just how broad or how narrow do you have in mind when you refer to the scientific community?

Dr. PICKERING. I am thinking of something like the present technical panel on the earth satellite program which is under the IGY activity but which is inviting contributions from all of the scientific community interested in this type of program. I am also thinking of one other activity and that is the upper atmosphere rocket research activity in this country which has been coordinated on essentially a voluntary basis by the scientists interested in this program.

Here again the people concerned have gotten together and have tried to make an organized and systematic program. I would believe that something like this rocket research panel or the IGY technical panel on the earth satellite program, something of that sort, could very well continue, possibly under the support of the National Science Foundation.

Mr. SISK. Of course, I would appreciate it when you and Dr. DuBridge extend your remarks, which I assume you will be permitted to do in the record, if you will comment on what extent you feel we should carry on worldwide scientific cooperation; realizing, of course, the contribution of security and so on. I do not want to take the time of the committee now to go into that, but I do think it is significant in this particular field.

As I understood your statement, Dr. DuBridge, you feel that definitely this exploration of space is something that should not be overly classified as I understand.

Dr. DUBRIDGE. That's right, and I think it should be international because a space vehicle is not like an airplane. An airplane can circle around over a particular country and stay within the boundaries. A satellite knows nothing about boundaries, it has to cross international boundaries all the time. Therefore, it is almost inherently an international object, although one country sends it up. Also it is almost inherently impossible for a country to prevent its crossing its boundaries. Therefore, you have the inherent problem of internationalization built into the satellite. Therefore I would like to see this properly taken advantage of and exploited. We should take the lead, as the President has done, in proposing international collaboration in peaceful satellite and space exploration.

It certainly is a fine way to take a lead on international cooperation.

Dr. PICKERING. Supposing, for example, you consider a problem, stepping beyond the satellite to an interplanetary type of vehicle. Here is a vehicle traveling out into space to Mars. You are sitting on the earth and you are interested in what is happening to that vehicle. The earth is turning around every 24 hours. If you want to look at the vehicle you will have to have a ring of stations around the earth, probably around the equatorial regions. Most of those stations will not be on United States territory, so again one is forced into international cooperation in such a program.

Mr. SISK. In these comments you may put in the record if you feel there is any implication or any application wherein the bill which we have before us might require some legislation or some authorization for NASA to provide our part of the worldwide cooperation.

Mr. Chairman, thank you.

The CHAIRMAN. Either the NASA or the State Department.

Mr. SISK. Or the State Department or such other agency; in other words, whether or not note of that should be made in the legislation.

Thank you, Mr. Chairman.

The CHAIRMAN. Mr. McDonough.

Mr. MCDONOUGH. In connection with our discussion this morning about the research and scientific authority of this Agency and its operational authority, since the recess I have found a document that outlines a National Space Establishment. It is the recommendation of the American Rocket Society and Rocket and Satellite Research Panel.

It is dated January 4, 1958, which is comparatively recently. I think in that connection that it would be a good place to insert it in the record.

The CHAIRMAN. Without objection it is so ordered.

(The document referred to follows:)

The American Rocket Society and the Rocket and Satellite Research Panel have independently studied a national program for space flight. This summary document, prepared by officers of both of these organizations outlines the basic premises which are common to both of these proposals.

SUMMARY OF PROPOSAL

It is proposed that there be created a national space flight program and a unified National Space Establishment for the purpose of carrying out the scientific exploration of outer space.

It is imperative that the United States establish and maintain scientific and technological leadership in outer space research in the interests of long-term human progress and national survival.

1. *Role.*—The role of the National Space Establishment shall be to unify and to greatly expand the national effort in outer space research and in the practical utilization of space capabilities specifically excluding space weapon development and military operations in space which are considered to be the responsibility of the Department of Defense.

2. *Mission.*—The broad mission of the National Space Establishment shall be to establish United States leadership in space research and other nonmilitary space operations by 1960 and to maintain it thereafter.

Accomplishment of this mission requires the following specific achievements:

(*a*) An intensified program of scientific soundings with high altitude rockets, immediately.

(*b*) An intensified program of scientific and technical developments with small instrumented satellites of the earth, immediately.

(*c*) Impact on the moon with nonsurvival of apparatus, by 1959.

(*d*) Placing an instrumented satellite in an orbit about the moon, by 1960.

(*e*) Launching of an instrumented vehicle, into an independent heliocentric orbit between Earth and Venus by 1960, to improve the accuracy of astronomical constants, and to explore environmental conditions in interplanetary space (meteoritic matter and interplanetary plasma).

(*f*) Impact on the moon with survival of scientific instruments, by 1960.

(*g*) Sending an instrumented comet to circumnavigate the planet Venus by 1961

(*h*) Returnable, manned satellites in flight around the earth, by 1961 or 1962.

(*i*) Small inhabitable permanent satellites by 1963.

(*j*) Manned circumnavigation of the moon with return to the earth, by 1965.

(*k*) Manned expedition to the moon by 1 or 2 men by 1968.

(*l*) Establishment of a permanent human base, if desired, beginning 1970.

(*m*) Fast-manned reconnaissance flight to Mars and Venus without landing, beginning 1972.

A thorough analysis of existing capabilities shows that all of these objectives are within reach of a unified, vigorous national effort.

3. *Administrative status of National Space Establishment.*—(*a*) It is strongly desirable that the NSE be given statutory status as an independent agency in order that its work can be freely directed toward broad cultural, scientific, and commercial objectives. Such objectives far transcend the short term, though vitally important, military rocket missions of the Department of Defense.

(*b*) If the proper creation of an independent agency is judged to require an intolerable delay, then it is believed that the statutory existence under the Secretary of Defense (but not within the jurisdiction of anyone of the military services) will be a workable arrangement for the immediate future. But in this event, it is urged that the charter of the agency explicitly provide for its independence as soon as its stature and achievements make this advisable.

(*c*) It is emphasized that the National Space Flight Establishment should not have "defense" missions in the direct sense of this word, since such missions would necessarily place it under the jurisdiction of the Department of Defense. The military use of space and the development of space weapon systems should be directed by the Department of Defense, whose duty it is to coordinate the weapon development of the three military services. By separating the above-mentioned scientific, cultural, and commercial objectives of the NSE from the military objectives of the Department of Defense, the eventual administrative separation of these two agencies becomes clearly desirable.

(*d*) It is explicitly advised that the National Space Establishment not be placed within the jurisdiction of any 1 of the 3 military services. There are many reasons, growing out of extensive professional experience, for this view. The military services are basically operating agencies, not research ones. The research talent of any branch of the military services is almost inevitably turned toward helping meet short-term, limited objectives. Such a point of view would assure the failure of a National Space Establishment in its broad mission—which is truly a national one, far beyond the mission of any one of the services or the Department of Defense taken as a whole. During the early phases of space research, it is evident that existing facilities and existing missile technology of the Department of Defense can make enormous contributions. The National Space Establishment must be set up in such a way that it enjoys the unqualified support of all three services, and not merely one of them. Such a situation is believed to be possible only if the NSE is an independent agency from the outset or if it is directly responsible only to the Secretary of Defense during its early years—with the clear prospect of independence at the earliest possible date.

(*e*) There must be clear channels for mutual cooperation between the proposed NSE and all levels of the Department of Defense, in order to assure no jeopardy of short-term, vital military need on the one hand and in order to assure maximum rate of advance of space research on the other.

4. *Remarks on the long-range importance of space research.*—It is already clear that international leadership hinges, to a very great extent, on preeminence in scientific and technological matters.

Space research will contribute enormously to the educational, cultural, and intellectual character of the people of the United States and of the world. Indeed, the exploration and eventual habitation of outer space are the finest examples of the "endless frontier." It is for such bold endeavors that the highest motives of men should be invoked.

There will be a rich and continuing harvest of important practical applications as the work proceeds. Some of these can already be foreseen—reliable short-term and long-term meteorological forecasts, with all the agricultural and commercial advantages that these imply; rapid, long-range radio communications of great capacity and reliability; aids to navigation and to long-range surveying; television relays; new medical and biological knowledge, and so forth. And these will be only the beginning. Many of these applications will be of military value; but their greater value will be to the civilian community at large. (To use a homely example, the telephone is certainly a valuable military device, but its importance to the civilian population is vastly greater.)

5. *Availability of technical experts for consultation and participation.*—The Rocket and Satellite Research Panel as well as the technical committees of the American Rocket Society comprise a broad membership of persons of extensive experience in all aspects of the proposed program of outer space research. Its

members are professionally dedicated to national leadership in this field. They offer their services, individually and collectively, in the conduct of the broad mission of the National Space Establishment.

JAMES VAN ALLEN,
Chairman, Rocket and Satellite Research Panel.
GEORGE P. SUTTON,
President, American Rocket Society.

JANUARY 4, 1958.

Dr. DUBRIDGE. Dr. Pickering was a member of this panel and signed this report.

Mr. MCDONOUGH. James Van Alen is one of the signatories and George Sutton is.

Dr. PICKERING. Yes.

Mr. MCDONOUGH. They have made some comments and excellent recommendations here and I think these are in the purview of what this agency would be doing on the basic research and development.

One other point. The other day we were discussing Sputnik No. 2 and I asked the question of how much data we were able to decode from our tracking stations from Sputnik No. 2. They told me to ask you the question, Dr. Pickering because the party I asked did not know.

If we were not able to decode the messages correctly then do you think that Russia was able to obtain more information on outer space in their electronic impulses than we did from ours? First, did we get information directly from it?

Dr. PICKERING. Well, in discussing Sputnik 1 and 2 together, the first information, the primary information, the easiest information to get, was to trace the orbit and to ask ourselves the question, can we learn something useful by analyzing it, the orbit. The answer is "yes," we can and we did.

We learned some facts about the air density which we had not known.

Mr. MCDONOUGH. That is on both one and two or especially two?

Dr. PICKERING. Both of them, about the same, Now the next thing is that as far as the signals from the sputniks are concerned there is one class of experiment which the Russians decided to do and which we did not. Namely, that was ionosphere experiments. The Russians said in effect this is the first time we will put something above the ionosphere which surrounds the earth and we will get signals through the ionosphere and perhaps we will learn something useful.

So they chose their radio frequencies partly with this in mind.

This means now we have a great deal of data which has been collected just by listening to the signals. Without analyzing the signals at all but listening to them, determining their signal strength variations and other electrical properties of the signals. This data has been collected and is in the process of being analyzed. This will be just as useful to us as it is to the Russians.

The third class of information is what kinds of information are you actually sending down on the radio communication link? At this stage of course then you got into trouble because if you listened to the signals you observed that the signals change in some fashion as time went on.

Now the Russians made the statement that the temperature of the instruments was measured by the length of the pulse on the signal. We observed the pulse changing in length, so the temperature was changing. How many degrees was it changing? We would have to ask the Russians for that because we didn't know the calibration.

We just knew there was a change, assuming they were correct when they said the length of the signal was a factor in the change of temperature.

Mr. McDONOUGH. The temperature changed at the different points, in the orbit.

Dr. PICKERING. It is colder in the shadow than it is in the sunlight, this sort of thing, nevertheless here is a piece of information which was coming from the Russian satellite which they said was temperature, which we observed was changing, and it could have been temperature but we have no means of interpreting unless they tell us what the calibration is. On Sputnik No. 2 there is some evidence that the signal which was transmitted was a fairly complex signal. It seemed to have quite a lot of information contained in it and the Russians have not told us what that was.

I think we must also raise this possibility, that just as on Explorer No. 3 we have a transmitter which is turned on when it passes over one of the minitrack stations (that is the tracking network of stations which extend down the coast of South America) every time it goes by you essentially ask it "What do you have?" and it tells you what is on the tape recorder. It runs out in 5 seconds, 2 hours of tape recording.

Mr. McDONOUGH. Does that mean that at each minitrack station we get that information?

Dr. PICKERING. Yes, sir, the minitrack station it is closest to. Every time it goes around the world it comes fairly close to one minitrack station so as it goes over you ask the question, "What do you have on the tape recorder?" It runs out the tape recorder in 5 seconds and tells you what it has. Presumably the Russians could be doing something very similar. In other words, every time the thing came over Russia they could say "What have you recorded in the last pass or couple of passes?" and they could have a tape recorder aboard that and they might be getting information in that way which, of course, we have no information about.

In fact, the list of items which they said were included in Sputnik 2 implies that they probably were doing this sort of thing. In other words, although I said the signals from Sputnik 2 were relatively complex I do not believe they were quite complex enough to have included all the sorts of data they said they were measuring, cosmic rays, solar activity, biological effects, temperature, meteorites, and so forth.

You link all this together and I think it calls for a transmitter which is turned on on command, perhaps when it is over Russia.

Mr. McDONOUGH. In addition to the complex signals you got from Sputnik No. 2 what was the advantage of its weight except to prove that they had a bigger engine than we have, bigger thrust engine

Dr. PICKERING. To carry the dog would require a fair weight. Just how much I do not know but I would guess a matter of several hundred pounds to build a container, put the dog in it, and keep him alive. It would have to be a fairly appreciable fraction of the total weight

Mr. McDONOUGH. So its size was to carry the dog rather than to carry additional instruments that might reflect additional signals to the minitrack stations in Russia? It weighed 1,100 pounds, did it not?

Dr. PICKERING. 1,100 pounds was their statement; yes.

Mr. McDONOUGH. That seems larger than necessary to carry the dog and instruments.

Dr. PICKERING. Yes. Again it depends on the instruments and how much you have tried to miniaturize your instruments.

They have shown photographs of some of the instruments on that device and it does not look as if they took any great care in trying to make them very compact.

Mr. McDONOUGH. Has there been any attitude on the part of the Russians to cooperate with us on the exchange of data, willingly?

Dr. PICKERING. The Russians have not given us any details, any detailed scientific data from either sputnik 1 or sputnik 2. The IGY agreements give them 8 months to do this. The 8 months on sputnik 1 I suppose is just about up, so that they owe us some data.

Mr. FORD. Is the 8 months from the end of the IGY year or 8 months from the time of the experiment?

Dr. PICKERING. I am not sure how that was worded but I believe that the implication is 8 months from the time you do the experiment.

Mr. McDONOUGH. Do you have any opinion as to why the Russians have not shot another satellite into orbit since it has the last two? It has been quite a space of time here during which time we have been shooting ours up.

Dr. PICKERING. No, I have no opinion. I am surprised.

Mr. McDONOUGH. That is all, Mr. Chairman.

The CHAIRMAN. Mr. Keating.

Mr. KEATING. Have you advanced farther, Dr. Pickering, in miniaturizing our equipment than the Russians have?

Dr. PICKERING. I will put it this way. On the Explorer, for example, we had cosmic rays, temperatures, and meteorite experiments.

I feel that we did a pretty good job of getting a lot of scientific instrumentation in that 20 pounds total weight. Whether the Russians have tried to do this, whether they have had to do this or not, I don't know.

The indication is that they have got very large vehicles available, so why worry about it, and this could be their attitude.

Mr. KEATING. I gathered from what you indicated however, you thought there was a little padding in their claims as to the information they were getting from their own experiments?

Dr. PICKERING. No, I did not want to imply there has been any padding. I merely wanted to say that I felt that taking their claims as literally correct, that they must have had a transmitter which was turned on over Russia in the same fashion that our transmitter is turned on over our minitrack stations. Most of the information then is contained in that transmitter.

Mr. KEATING. Would it be your judgment that they have gotten more information out of their equipment than we are getting out of ours to date?

Dr. PICKERING. Well, they have done more experiments.

Mr. KEATING. I mean out of their satellites?

Dr. PICKERING. Yes. They have done more experiments with their satellites. If nothing else, they have had a dog up there and they have made some measurements on the dog which we certainly have not done?

Mr. KEATING. Is it not a fact that they did not follow the radio frequency which they had promised to use.

Dr. PICKERING. There is a misunderstanding about that. The IGY went on record as favoring the 108-megacycle frequency which the United States had selected and the Russians said that they would

take the matter under advisement. They did not actually agree, as I remember it, to actually operate on 108 megacycles.

Mr. KEATING. It was anticipated they would, was it not?

Dr. PICKERING. Yes, but, several months before they sent up their satellite, they published the fact they would be operating on 20 and 40 megacycles.

Mr. KEATING. So, you knew, some months ahead of the time they shot the satellite around, they were not going to use the frequency.

Dr. PICKERING. We knew they were going to use 20 and 40 megacycles. We did not know those were the only frequencies they were going to use.

Mr. KEATING. Dr. DuBridge, on page 2 of your statement you say that to leave the earth you have to go about 25,000 miles an hour, roughly.

Dr. DUBRIDGE. Yes.

Mr. KEATING. Now you say if we work the thing out so that we can go 5 times faster than that it still is going to take 10,000 years to reach the nearest star. Now, we are all going to be pretty old. You hear all this talk about going to the stars. Now I want to ask you this. You know, we get great stories here. I want to ask you if this is an old wife's tale or a scientific fact. I have been told that when you get up there in outer space you become ageless, or time does not count; therefore, in 10,000 years you only pass a year or something. Is there anything to that? If that is not true, what is the fact about time?

Dr. DUBRIDGE. I have been dealing here with velocities which are some thousand times less than the velocity of light. That is, the velocity of light is 186,000 miles per second. I have been dealing here with velocities of only 30 or 40 miles per second. The effect that you talk about is an effect that is observed only when one is up to maybe 95 or 99 percent of the velocity of light.

In other words, there is no appreciable time contraction until one gets an object which is approaching the velocity of light; that is something like 180,000 miles per second. When you get up to that velocity, or above, you do begin to get a time contraction in accordance with the theory of relativity. But that velocity is so far beyond any velocity we can now conceive of obtaining with any available object, I have dismissed all relativity considerations in my remarks.

If, at some unknown future time, one can learn how to get out into space and then to get a continuous acceleration which will take you more and more up toward the speed of light, then you will begin to get this contraction of time.

The CHAIRMAN. Would you live longer?

Dr. DUBRIDGE. In accordance with a stationary observer, yes.

Mr. KEATING. If it is going to take 10,000 years to reach the nearest star, and, at this rate, this is a rate that is almost inconceivable for a human being to move, is it not? This modest rate of 125,000 miles an hour?

Dr. DUBRIDGE. Speed does not hurt a human being. It is getting to the speed, or stopping, that hurts. Dr. Pickering reminds me that the earth's speed around the sun is 60,000 miles an hour, so that does not seem to hurt us much. It is not the speed that hurts, but the acceleration. What I am worried about, actually, is the energy, to give an object the energy required to get that up to a speed of 100,000 miles per second.

That takes an enormous amount of energy. It is quite difficult, as it is, to get these objects up to 25,000 miles an hour, or 4 or 5 miles per second, which I say is 50,000 times less than the velocity of light.

Mr. KEATING. How fast did you say the earth is moving now?

Dr. DUBRIDGE. Around the sun, it is moving 66,000 miles per hour.

Mr. KEATING. You and I, then, both of us, as part of the earth, are going around the sun at 66,000 miles an hour?

Dr. DUBRIDGE. Yes.

Mr. KEATING. The reason we can sit here and talk to each other is that we are both going at the same rate, so, vis-a-vis each other, we are stationary.

Mr. DUBRIDGE Yes

Mr KEATING. Is that the same principle on which you would be going around in outer space at 18,000 or more miles per hour and you send a refueling object up there and you get even with that and you can work there just as we are working here because you are both going at the same rate? Is that the same principle?

Dr DUBRIDGE That is exactly the same principle You are going at the same rate, but there is one little difficulty. If you are going in a certain orbit around the earth, then at every point in that orbit your speed is fixed and your period in the orbit is fixed. The laws of motion do not allow for any particular orbit, only for a particular period If you have two objects going around the same orbit, they are going at the same speed and one can never catch up to the other. As soon as it tries to catch up, it will go up to a higher orbit, whereby it will go slower and fall behind

Mr. KEATING You can catch up by giving it more propulsion.

Dr DUBRIDGE. Then you get into a different orbit.

Mr KEATING How do you marry these two things up there?

Dr. DUBRIDGE This is one of the difficulties that the space-platform experts don't always talk about It is the fact that, if you try to have one object and try to catch up with another one in the same orbit, if you try to speed up the one behind, then it does not catch up but it goes to a higher orbit and falls behind

Mr KEATING. They told us you could refuel these vehicles up there. There might be a little jiggle, but you could use electronic devices to maneuver.

Dr DUBRIDGE. Both are going around in a similar orbit, and the centrifugal force, the Coriolis force becomes very important. Therefore, we know when you try to make an object go this way you might have to shoot it this way in order to make it go that way, simply because there are enormous depletions in the apparent direction of motion due to these Coriolis forces, due to the fact that we are rotating around a central object, the earth It can be done if you adjust your propulsion in the right direction. If you want to speed up, you actually slow down, then you might be able to do it.

Dr PICKERING You might remember, on the sputniks, that, as the thing comes into the earth, it gets going faster and faster, it takes less time to go around. So, if you are sitting here on the sputnik and you watch the rocket, instead of the rocket slowing down behind you, as you would expect it to, it is getting ahead of you.

Dr DUBRIDGE. The more friction slows it down, the faster it goes.

Mr FORD Will you repeat that again?

Dr. DuBridge. That is because, as friction slows it down—it does not actually slow it; it simply falls to a lower orbit—draft pulls it in and the speed goes up as it gets lower.

Mr. Ford. Going around the earth faster, or at a faster speed?

Dr. DuBridge. Both; actual linear speed and shorter period

Dr. Pickering. A satellite going around just outside the atmosphere goes about 5,000 miles a second The moon out here 250,000 miles is a satellite going around the earth, but it only goes about 3,000 miles an hour. The higher you go the slower you go.

Mr Keating. The higher you go the slower speed at which you can still keep in orbit.

Mr. Pickering. That's right.

Mr. Keating. Does the absence of a gravity field have any effect on time?

Dr. DuBridge Yes. This is an experiment that some of the physicists would like to do This is a very tiny effect on the rate at which a clock goes, and you can think of an atom vibrating as a clock if you wish. There is a slight effect, the relativity effects on the rate of a clock depending on the gravitational field in which it is located. All clocks on earth of course are in the earth's field. If you could get out a thousand miles that would be a 30 or 40 percent lower gravitational field, therefore there should be a slight change in the rate of a clock but it is only one part in 10 billion or less.

Mr. Keating. Oh, well——

Dr. DuBridge It is of great theoretical but very little practical importance.

Mr. Keating. Is there more to be learned scientifically in a lunar probe which we have learned so much about, from exploring around the moon and looking at it, than there is by actually hitting it?

Dr. Pickering. I would say yes, there is. If you hit it you are done. You hit it once and that experiment is all over. But if you are going out in the vicinity of the moon you might make observations first of all of different parts of the moon, just looking at it, photographing and so forth

Or I could measure the magnetic field of the moon I could measure any electric field due to particles coming from the sun I could measure any residual atmosphere that the moon may have. I can do quite a few things by going near the moon without actually hitting it.

Mr. Keating. It is easier to go somewhere near the moon than to hit it?

Dr. Pickering. Fortunately, yes.

Mr. Keating. Would we know if we hit it now? Maybe I am getting into something classified. But with present equipment would we know if we hit it?

Dr. Pickering. If one considers a relatively small instrumented device going out near the moon and you ask "would you know if you hit it," I would say if you were listening to it and all of a sudden it stopped you might decide it had hit the moon.

Mr. Keating. It might hit a meteor.

Dr. Pickering. Yes, or looking at this thing, how big the moon was and you see it getting bigger and bigger and all of a sudden the thing stops, you might decide you hit it.

Mr. Keating. What stops?

Dr. PICKERING. The signal.

Dr. DUBRIDGE. What he means is if you are taking a TV picture of the moon and it is getting bigger and bigger and then suddenly it goes black.

Mr. FORD. Is it conceivable that when you hit it, it might have some substance that it might not cause such an impact.

Dr. PICKERING. We know there is rock up there. There may be dust on it. The astrophysicists debate how much dust there is on the surface of the moon but there is rock beneath the dust.

Mr. KEATING. How big a dye mark would you have to put on the moon to tell in that way you have it, by telescope?

Dr. PICKERING. If you think of it in this sense that the moon is about 2,000 miles across and how big a fraction of the moon now do you want to cover with dye? Whatever your answer comes out that will be it. If you had 1 square mile it would not look very big in a 2,000-mile diameter device.

Mr. KEATING. Could you see a 1 square mile mark from the earth?

Dr. DUBRIDGE. Just about, with a 200-inch telescope.

Mr. KEATING. I have heard of this talk about putting a dye marker on the moon. I wondered how big an object in the way of a dye you would have to put up there to make it visible to be sure in that way that you had hit the moon

Dr. DUBRIDGE. Something like a square mile.

Dr. PICKERING I would prefer 10 square miles to 1 square mile.

Mr. KEATING. How much dye would it take to do that?

Dr. DUBRIDGE. That is an experiment we could try on earth, to take enough dye to cover 10 square miles of the earth.

It would be a few tons.

Dr. PICKERING. If the moon had a thick layer of dust on it, the dye might disappear under the dust.

Mr. FORD. To identify if you hit it by means of a dye marker, would you have to hit it in an area that we could observe, people sitting here on the surface of the earth and looking at the moon. In other words, you have to hit it on the yellow part in order for us to know. Is that right?

Dr. DUBRIDGE. Of course, all of this side is eventually illuminated by the sun. If this thing went around and hit the back side you never would know.

Mr. KEATING. Gentlemen, there are a thousand other questions along this same line I would like to ask you but I cannot take the time of the committee. I do want to ask you a couple of questions about other aspects of your statement, Dr. DUBRIDGE

I was very much pleased by your statement on page 6:

> I trust that the United States will take the lead in urging that outer space be used by all nations exclusively for peaceful purposes.

Now the President has made statements to that effect. Several Members of Congress, including myself, have resolutions saying that it be the sense of Congress that outer space only be used for peaceful purposes.

Now I realize that could be open to attack of being simply a pious declaration.

Don't you think it would be helpful to our position if the Congress of the United States were to enact legislation along those lines?

Dr. DuBRIDGE. I feel so very strongly, Mr. Keating. I think we have a hard time in our propaganda battle with Russia. We have somehow let the Russians pose before the nations of the world as the peace-loving people and we have not taken as many positive moves toward peaceful things as we might have. Here is one thing we could take without the slightest degree damaging our international security, in fact by improving it.

We could take a lead in advocating a peacetime collaboration of scientific exploration of space as an international enterprise.

I would go further and say that it seems to me that if we attempted a military capture of the moon, for example, that this would quite properly and naturally be resented by the Russians, which would initiate them to take some counteraction.

So that our capture of the moon might well initiate a nuclear war which is the very thing we are trying to prevent. I do not want to get into a nuclear war over who owns the moon. I am willing to fight a nuclear war to keep the Russians off the United States, but to get in a nuclear war over the possession of the moon I think is quite a lot to ask of either the people of Russia or the United States.

This is another reason why a peaceful international collaboration on peaceful space exploration is a thing to be desired.

The CHAIRMAN. If anything like that is done, the time to do it is before the fact rather than after the fact.

Mr. KEATING. That is right. I entirely agree with the chairman. If anybody, including ourselves, or any other nation really once gets a foothold out there it will be an awfully lot harder to get across this idea that that must be a peaceful area out there.

You have the problem of inspection and being sure that somebody does not do you dirty, but just the same it is at least, I think, a constructive step along the right line.

Dr. DuBRIDGE. The Russians might not collaborate but we could make the move. We could initiate proposals and develop a plan. This, for a change, would put us in the position of a peaceful nation rather than a warlike nation. It would be to our advantage to do it.

Mr. KEATING. Let me ask you a word or two about the setup of this Board. You favor this administrative setup, but you would prefer to see the Board at the top and the Director reporting to the Board.

Certainly if you have that, you have to have a Board meeting much oftener than four times a year?

Mr. DuBRIDGE. Yes. Once a month I would think and probably 2 or 3 days at a stretch.

Mr. KEATING. Even under this plan where they consult with the Director, even there you have to have the Board meet more often than four times a year but not as often perhaps as under the setup you propose?

Dr. DuBRIDGE. Yes.

Mr. KEATING. Do you think we ought in this legislation, which is now framed to say not less than 4 times, to actually provide in the law for something more than 4 times a year?

Dr. DuBRIDGE. Yes. I hesitate to put too many detailed requirements in the law on the board and yet I think it would be ineffective if less than six meetings a year were held and it would do no harm to make that as minimum and then let the board adjust its meetings as

the need arose. If you have a conscientious board they will meet as often as needed to do the job. May I ask a question, have you thought about the compensation of these board members who meet a few times a year?

Mr. FORD. Up to $100 per day.

Mr. KEATING. I think that is for consultants.

Mr. FORD. It says on page 4:

Such members shall be paid travel expense and per diem in accordance with provisions relating to persons serving without compensation under section 5 of the Administrative Expenses Act of 1946

Dr. DUBRIDGE. That means $12 to cover hotel and meals

Mr. KEATING. The $100 per day relates to consultants.

Dr. DUBRIDGE. I would like to suggest that $100 a day stipend in addition to expenses be allocated to the members of the board, too, because they won't break even on the Government travel.

Mr. KEATING. Of course, they would be coming from distant places. I would hope some would come from California and that is something to consider Now just one other question. This setup provides for 17, 8 from government and 9 from outside, and it says that the Chairman of the Board shall be an outside member. The suggestion was voiced by 1 or 2 witnesses that that restriction should not be on there, that it should be possible to name the Chairman from either "in-house" or "out-house," how do you feel about it?

Dr. DUBRIDGE. I feel strongly that the Chairman should not be a Government employee, should not be one of the Government representatives, that he should be a public representative on the Board.

Mr. KEATING. Tell us why.

Dr. DUBRIDGE. In the first place the Government representative will have a full-time job in Government from which it will be difficult for him to take too much time off.

Second, it is quite possible he will be in a position where he will have interests which may conflict with other interests in the Government in the space field, I mean if you choose an Army man the Navy would not like it, for example, and there may be other conflicting interests.

I would prefer to get an extremely outstanding, distinguished man, a man who stands high in public regard in scientific and engineering circles, industrial circles, a great American figure, as the Chairman of this Agency.

Mr. KEATING. I want to say, Mr. Chairman, that I feel that these two witnesses today have really given us a great deal of valuable and useful information and I am delighted to have had the privilege of being here and listening to these two gentlemen.

The CHAIRMAN. The whole committee agrees with you.

Mr. Ford?

Mr. FORD. Following up a question or two asked by Mr. Keating, Dr. DuBridge and Dr. Pickering, the question of $100 per day, for example, do you mean all inclusive, both the Government and the outside?

Dr. DUBRIDGE. No; it would not be legal to pay the Government representatives extra.

Mr. FORD. You make the distinction between the members who represent the Government agencies and those who come from the outside.

Dr. DuBridge. I was thinking of the outsiders who come in from private universities and business and give their time to this.

Mr. Ford. We have not had much discussion about the term of the Director. As a matter of fact, I find nothing which indicates how long the Director shall serve. I presume that it is at the pleasure of the President.

Do you feel that that is preferable to a set term?

Dr. DuBridge. Yes, for the Director I think the Board members should rotate.

Mr. Ford. They have 4-year terms and it is anticipated that they shall be staggered?

Dr. DuBridge. Yes.

Mr. Ford. But the Director should be on a no-term basis?

Dr. DuBridge Yes, he should serve at the pleasure of the President or the Board. So he might serve for 10 years or he might be asked to resign in 1 year

Mr. Ford The question that bothers me is the representation of the Department of Defense in this picture. It seems to me that it is preferable that we have, at this point, greater representation by the Department of Defense.

I know it says there can be more than a minimum of one. How do you feel about that at this time?

Dr. DuBridge. Assuming we stay with a 17-man board of which up to 8 are Government representatives and 9 are from outside, let us assume that we keep the limit on Government representation at 8, you will certainly want a representative from the National Science Foundation, from the Atomic Energy Commission, probably from the Weather Bureau, probably the Department of Health, Education, and Welfare some place, Public Health Service; so there are 4 Government representatives that you will probably want.

Maybe someone from the National Bureau of Standards. In other words, there will be quite a number of Government agencies which will have technical or scientific or research interests and that you will want represented.

Now if you in addition require that there be Defense, Army, Navy and Air Force, then you will have four taken up there.

So I would be a little afraid that if you required four from the Defense Department, all the agencies, that there might not be enough to represent the other Government agencies.

I think it would be nice to have a representative of the Central Intelligence Agency to help in providing information about what other countries are doing. You can think of quite a number of Government representatives that ought to be among the eight.

So I would hope that the Secretary of Defense might be able to name 1 civilian representative and let us say that the Joint Chiefs of Staff might be able to select 1 military representative to represent all the military services and have 2 from the Defense Establishment. This would be my thought about it.

Mr. Ford. Dr. Pickering, on page 3 of your prepared text you say this:

> The proposal contained in the President's message of April 2 appears to embody most of these objectives.

I am not clear what you are indicating there.

Dr. PICKERING. By the "most"?

Mr. FORD. Yes.

Dr. PICKERING. I think it is just academic conservatism.

Mr. FORD. It seemed to me from reading that paragraph which appears before that paragraph——

Dr. PICKERING I do not know whether there is any specific statement about long-term funding which I think is a rather important thing.

Mr. FORD. That is the bill, as you know.

It says on page 15, section 9 (a)—

There are hereby authorized to be appropriated without fiscal year limitations

and so forth, which gives the no-year funds which I think is most important. I think you may be referring to the need for that.

Dr. PICKERING. Yes, I certainly think it is necessary.

Mr. FORD. One thing bothered me. About 2 weeks ago I kept reading over the weekend the anticipated expiration of Sputnik No. 2's life.

First, it was going to be on a Friday, then on a Saturday and then Sunday; then finally it expired Sunday night or Monday. Was there any significance to the fact that we could not precisely forecast that?

Dr. PICKERING. No; it just means that we were not able to analyze that kind of decaying orbit accurately. In other words, the life is determined as it comes into the atmosphere by the drag on the object, as it gets into the atmosphere. This is determined by the exact shape of the object, the exact orientation because it won't be streamlined into the breeze.

It may be plowing through this way and that way.

Mr. FORD. And the texture of the material?

Dr. PICKERING. Eventually the kind of material when it becomes very hot, how the material melts and so forth.

There are quite a number of uncertain factors in there. I think to predict it within 2 or 3 days was quite good.

Dr. DUBRIDGE. If one had a large sphere one could predict its behavior much more accurately because you would know what shape it was presenting to air resistance.

Mr. FORD. Have we learned anything about cosmic rays and meteorites from our own two Explorer satellites?

Dr. PICKERING. Yes, indeed. I do not know that I want to discuss them in any detail but I want to say particularly the cosmic-ray data has turned out to be quite interesting and quite unexpected.

Mr. FORD. Have we been surprised by anything we have learned in any of these fields?

Dr. PICKERING. Yes, in the cosmic ray field; yes.

Dr. DUBRIDGE. A report is being prepared on this to be released next week. I am not familiar and I am not sure you are familiar with the content of it. Se we will let the IGY release the report next week.

Dr. PICKERING. The IGY is preparing a report on the scientific information from the Explorer.

Mr. FORD. Speaking of the signals you got back from Sputnik I and II, we have some real experts on decoding in the National Security Agency.

Dr. DUBRIDGE. No use at all.

Mr. FORD. Their equipment does not have any applicability to this?

Dr. PICKERING. No. To take a simple example, I can have a thermometer in here and I can say 10° on that thermometer will represent half a second change in the pulse length or I could make 100° represent half a second. I have absolutely no way of telling whether it is 10° or 100°.

All I can say is that the pulse length changes, that is all. It is not a case of trying to decode it. We do exactly the same thing. When we are sending information down from a missile or satellite we have to put the information in such a form that it can be transmitted over a radio signal.

The exact form you put it in is obviously at the discretion of the experimenter but it is not because you are trying to be secretive about it; it is just that you have to put it into some form and the calibration then is the important thing.

In other words, here's a meter which reads like this. Now what is the meter reading? It can tell you anything you like, you see.

Dr. DUBRIDGE. These are not verbal messages that are being sent down in Morse code. These are instruments that are imposing a change of some sort on the radio signal. Only the fellow who designed it knows what signal is put in what way, on what signal.

Mr. FORD. The code itself has no significance but the relationship to the instruments?

Dr. DUBRIDGE. The calibration rather than the code.

Dr. PICKERING. I might point out in this respect by the way that the telemetering calibrations on the United States satellites have been published, have been made available to the IGY.

The Russians have not.

Mr. FORD. Do you feel that there has been any reconnaissance capability in Sputnik II?

Dr. PICKERING. That is a difficult thing to answer. If Sputnik II can carry a thousand pounds I suppose this is beginning to get up to the sort of weights which you need for reconnaissance capability but beyond that I have no comment.

Mr. FORD. I want to join in complimenting both of you, Dr. DuBridge and Dr. Pickering, on the very helpful and valuable contribution.

Dr. PICKERING. Thank you.

The CHAIRMAN. Mr. Hays?

Mr. HAYS. Doctor Pickering, you spoke of 3 items that you picked up from 1 of the Explorers, cosmic rays, meteorites and what was the other?

Dr. PICKERING. Temperature.

Mr. HAYS. You got readings on all three items?

Dr. PICKERING. That is right. It did exactly what it was supposed to do so far as giving us scientific information.

Mr. FORD. May I ask one further question along that line? If we had not launched Explorer II and we had not gotten this information on cosmic rays, could we have conceivably gotten it from other sources and if so, how long a time would it have taken?

In other words, what was the benefit of getting it this way?

Mr. PICKERING. Let us say we have two ways of exploring the very high atmosphere above the earth or space in the vicinity of the earth. One way is to send a satellite around the earth, the other is to send a rocket straight up from the surface of the earth.

Rockets have been sent up to altitudes of 100 to 200 miles. Now satellites are flying at considerably higher altitudes. In principle one can send instrumented rockets up to even higher altitudes than we have done, so one could get data this way. The disadvantage of the rocket is that it is only up there for a few minutes, whereas a satellite is up there for days.

Take, for example, the cosmic ray phenomena. The cosmic ray phenomena tend to be dependent on the position on the surface of the earth, on the particular state of activity of the sun and magnetic storms on the earth.

Now these things are things which vary from time to time. So if one is really going to analyze what is going on one would like to have data coming in over a long period of time. So, desirably then, this is the way to do it.

Mr. FORD. And probably the only way?

Dr PICKERING. The only way really, yes.

The CHAIRMAN Is there any advantage with respect to what part of the earth the satellite is shot up from into orbit?

Dr. PICKERING. Yes. Again taking cosmic rays that is a sort of good example here. One of the things you are interested in is the magnetic field of the earth interacting with cosmic rays.

To really study this you would like to sweep across the whole magnetic field of the earth. This says you should send a satellite from pole to pole because the magnetic poles are up near the geographic poles. So you would like to send the satellite around that way instead of around the equator, as we have done to date.

The CHAIRMAN. Ours went around the Equator. How did the Soviets go?

Dr. PICKERING. It was nearer to the poles.

The CHAIRMAN. That is more difficult, is it?

Dr. PICKERING. It is more difficult in the sense that the energy required to launch is slightly greater in their case. There is very little difference, actually.

Dr. DUBRIDGE. You get a little bit more help from the rotation of the earth.

The CHAIRMAN. It would take more propulsion to send up one way or the other. Theirs is a little more difficult way?

Mr. PICKERING. Theirs is a little more difficult than ours.

The CHAIRMAN. The last one they sent up indicates a powerful propulsion?

Dr PICKERING. Yes, because the rocket on the first satellite was about the size of the second satellite which of course stayed as one piece. So the first satellite, if you looked at it as a rocket-plus satellite, was very much the same sort of size as the second one.

So both of them were very large.

The CHAIRMAN. I have been informed that the use to which these satellites can be put is manyfold, is that correct?

You can use them for almost any use except putting the human mind in there. In fact that came to me from a friend of mine who was on the faculty of MIT.

Dr DUBRIDGE. That is a little broad. I don't think there would be any use translating things in Greek language. There are lots of different possibilities.

The CHAIRMAN. Instruments can be put in there which can bring back information in practically any and all fields, not in one, and they can be utilized.

Dr. PICKERING. I think the other comment I would like to make is that the kind of information or the kind of application will obviously extend beyond our present concepts into many areas as to which at the moment we can't see exactly what we will do.

This is a matter of exploration. We don't know where the exploration will carry us.

The CHAIRMAN. But you know certain things definitely?

Dr. PICKERING. Yes.

The CHAIRMAN. From what you definitely know, you know that in our own national interest, from all angles, that it should be pursued?

Dr. PICKERING. Yes.

The CHAIRMAN. An agency of this kind is the best means from the civilian side to pursue our scientific activity level?

Dr. PICKERING. Yes, sir

Mr. McDONOUGH. Speaking about the extent to which we can observe through satellites, we are limited, however, from taste and smell, I imagine? You can feel and see. There is no taste and smell to an electronic impulse, is there?

Dr. PICKERING. Well, there is a vacuum up there; it does not taste very good.

The CHAIRMAN. Coming back to ourselves as human beings and our relationship to one another, progress oftentimes is made where the fear exists itself. I do not like it, but oftentimes fear produces it and I think sputnik produced some fear which brought along some affirmative force and action on our part. I am a believer in giving the American people all the information possible because public opinion is a powerful weapon in a democracy and if it is to be rational and sound it has to be informed as much as possible. I recognize the exigencies of national interest and so forth.

What other benefits to mankind might flow from these experiments on the part of our Government or any of our agencies, meaning public and private, and which are not classified for the time being?

Do you gentlemen feel it would be to our advantage to make it known to the public without regard to what the Soviet, itself, might do, even if they employ secrecy?

Dr. DUBRIDGE. Yes, for these peacetime experiments I think full publication of the results is extremely important. You see, if you don't publish them, then we don't know them either.

You can't pass secret letters around to every scientist and engineer in the United States who might be interested. So unless the results are published our own people will not get the benefit of them.

Until they are published they might not get the critical attention that some foreign expert might give them who might reveal additional ideas, new interpretations, new theories, suggest new experiments.

The advantage of publication of nonmilitary data are overwhelmingly in favor of the one who publishes it.

The CHAIRMAN. What is your view, Dr. Pickering?

Dr. PICKERING. I agree completely.

The CHAIRMAN. Assuming the Soviet Union did not make disclosures of information from their two sputniks that were not connected with the military aspect, that fact should not get us into an

isolationist's state of mind where, by way of reaction, we say, "We will not disclose any information even though it is not classified in the national interest of our country."

Dr. DuBridge. No; we would be interfering with our own progress.

The Chairman. We would be showing the world sincerity and that applies to all fields of research.

Dr. DuBridge. Yes.

The Chairman. Gentlemen, I call your attention to page 2 of the bill. On line four, "The Congress further declares that such activities should be"—well, we can change that to "shall" if you want to, don't you think, "shall" would be a better word than should.

Should has a qualification—

shall be directed by a civilian agency exercising control over aeronautical and space research sponsored by the United States except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations, in which case the agency may act in cooperation with, or on behalf of, the Department of Defense.

That means that the Defense Department makes the decisions as to what weapons may be peculiar to or primarily associated. Would you agree with that?

Dr. DuBridge. I do not see any other alternative actually. Only the Department of Defense can judge what specific things have specific peculiar military importance.

The Chairman. Suppose the new agency were to take the position that certain information is not peculiar to or primarily associated with weapons systems and military operations, what then?

Dr. DuBridge. How would the difference of opinion be resolved?

The Chairman. How would the civilian agency express its assumption the Defense Department was wrong? Suppose something was more or less peaceful, had peaceful use?

Dr. DuBridge. This is a problem of security.

The Chairman. Would it be your interpretation that then they could go to the President?

Dr. DuBridge. Take it to the National Security Council or the President. But on matters of secrecy and national security that is the Department of Defense responsibility and only they can have the access to all the information which would bear on the question.

The Chairman. You heard Dr. Furnas this morning talk about the mass of data that they have?

Dr. DuBridge. Yes, I know, this is a serious problem of the classification of information. This is one we face now in many areas and we have not solved. It is just a problem we face and you cannot solve that problem in this bill.

The Chairman. That is true. Are there any further questions? Mr. Feldman?

Mr. Feldman. Following the chairman's question in the last connection, there are many gray areas in this kind of situation?

Dr. DuBridge. Yes.

Mr. Feldman. For example, weather is something that certainly has a peaceful value?

Dr. DuBridge. Yes.

Mr. Feldman. The Signal Corps is interested in it, so is the Air Force and so is the Navy?

Dr. DuBridge. Yes.

Mr. FELDMAN. There are other situations just like that. So that maybe a recasting of this language, in order to be more specific, will be necessary. I don't say that it is, but I think it should be considered seriously.

Dr. DUBRIDGE. It seems to me this language is reasonably precise, that this Agency "Shall exercise control except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations."

Presumably that decision as to whether they are or not will have to be made by the Department of Defense in which case the Agency may act in cooperation with the Department of Defense or on behalf of it, in which case a collaborative mechanism will be set up.

The CHAIRMAN. In the world of today, having in mind the prominence and importance of the military, can you see much work for the new Agency to do? What will it have to do?

Dr. DUBRIDGE. Tremendous. There are hundreds of scientific problems which are of no foreseeable military concern or military application which space research will reveal. Cosmic rays, for example.

It may be very important for us to understand this cosmic ray phenomena, the way the sun behaves, its conceivable influence on our weather, lots of other things. Magnetic fields of the earth.

These have no specific military application.

The CHAIRMAN. The military could say they have. Under this language they can.

Dr. DUBRIDGE. You mean so the military can begin investigations of cosmic rays.

The CHAIRMAN. Suppose the military says that is a field primarily associated with weapons systems or military operations?

Dr. DUBRIDGE. I don't think anybody can claim that cosmic rays are peculiar to military operation or primarily associated with military operations.

The CHAIRMAN. Suppose the Defense Department says it is. They make the decision. This is clear language. You create a civilian situation but then you accept everything that is peculiar to or primarily associated with weapons systems or military operations. That covers everything.

Dr. DUBRIDGE. I am afraid you will have to leave that to good sense of the Defense Department, the new Agency or the President.

The CHAIRMAN. Should we put in language in case of difference of opinion that the matter can be submitted to the President? In other words, a precaution.

Dr. DUBRIDGE. You can provide an appeal mechanism.

The CHAIRMAN. That would not interfere with the military I am strong for the military angle. On the other hand if we are going to establish an agency I want to see some agency that has jurisdiction.

Dr. DUBRIDGE. You might provide an appeal mechanism in case of disagreement. You probably have similar problems within the AEC as to jurisdiction or classification. How are those resolved?

The CHAIRMAN. All right, Mr. Feldman.

Mr. FELDMAN. Doctor, the frame of reference for my next question is section 2, 6, of the proposed legislation which begins at the bottom of page 2.

I will read that language:

6 Cooperation by the United States with other nations and groups of nations in work done pursuant to this Act and in the peaceful application of the results thereof

Then I would refer you to section 6 (4) on page 6 which reads as follows:

Arrange for participation by the scientific community in planning scientific measurements and observations to be made through use of aeronautical and space vehicles, and conduct or arrange for the conduct of such measurements and observations; and provide as appropriate for dissemination of data collected.

How broadly do you interpret the words, "scientific community"?

Dr. DuBRIDGE. As used here, participation by the scientific community? Well, my interpretation of that would be extremely broad the way it is stated here.

The scientific community certainly, for example, includes scientists of all nations.

Mr. FELDMAN. That was my next question. Would you include scientists abroad?

Dr. DuBRIDGE. I would interpret that phrase, unless it was later excepted, as including scientists of all nations.

The CHAIRMAN. When you are editing your testimony you can in the meantime give consideration to that and elaborate, Doctor.

Mr. FELDMAN. The reason for it, Doctor, is that you know congressional intent is very often obtained from hearings and reports.

The CHAIRMAN. What among scientists does the term "scientific community" encompass?

Dr. DuBRIDGE. Unless it is qualified it would mean the scientific community of the world unless there is something in the context or qualification which restricts it.

You can talk of the American scientific community if you wish but unless it is qualified, I always interpret it as meaning the international community.

Mr. FELDMAN. Would you favor a broader definition?

Dr. DuBRIDGE. In case there is likely to be any doubt about it I would favor inserting a phrase and indicating the international scientific community or the scientific community of all nations or something.

Mr. FELDMAN. I have no other questions.

The CHAIRMAN. Any further question?

Thank you very much Dr. DuBridge and Dr. Pickering. You have been very helpful. Speaking for myself as chairman of the committee and all the members of the committee I extend to both of you distinguished gentlemen our thanks.

Dr. DuBRIDGE. Thank you.

May I thank you for your patience and courtesy.

(Whereupon, at 5:10 p. m., the committee adjourned to reconvene at 10 a m., Monday, April 28, 1958.)

ASTRONAUTICS AND SPACE EXPLORATION

MONDAY, APRIL 28, 1958

HOUSE OF REPRESENTATIVES,
SELECT COMMITTEE ON ASTRONAUTICS
AND SPACE EXPLORATION,
Washington, D. C.

The committee met at 10 a. m., pursuant to recess, in room 219, Old House Office Building, Hon. John W. McCormack (chairman) presiding.

Present: Representatives McCormack, Brooks, Metcalf, Natcher, McDonough, Fulton, Keating, and Ford.

Present also: George J. Feldman, director and chief counsel.

The CHAIRMAN. The committee will be in order.

We are very glad to have with us this morning the first witness, the Honorable Herbert Loper, Assistant to the Secretary of Defense for Atomic Energy.

Mr. Loper, we will be very glad to hear from you.

Mr. Loper, any questions asked of you that call for classified information, we expect you to tell us so.

Furthermore, you have permission to edit your remarks and in that way clarify what you wish to say.

STATEMENT OF HERBERT B. LOPER,[22] ASSISTANT TO THE SECRETARY OF DEFENSE FOR ATOMIC ENERGY

Mr. LOPER. Thank you, Mr. Chairman. I have no prepared statement.

Mr. Chairman, it was my understanding that you were interested in looking into the functions of the Military Liaison Committee to the Atomic Energy Commission.

I have prepared a small folder here for each of the members of your committee which sets forth some background information. I do not particularly call them to your attention now, but it may be pertinent in the course of our discussion this morning to refer to some of these documents.

---

[22] Loper, Herbert B(ernard), retired army officer, government official, born at Decatur, Kansas, on October 22, 1896, the son of Gilbert Lafayette and Hulda Belle (Scott) L, A B, Washburn Coll, 1916, B. S., U S. Mil Acad, 1918, B. Comdr of Brit Empire, spl Collar Order of Yun Hui (China) Mem Am Soc of Mil Engrs., Tau Delta Pi. Home: 1 Tallyho Lane, Alexandria, Va Office Sec. of Defense, Washington.

I think they will be useful in understanding the organization and the functions of the Military Liaison Committee.

It was my understanding that it was a consideration as a means for insuring liaison between the Department of Defense and the agency with which you are concerned as a basis for insuring the proper type of coordination.

The Military Liaison Committee is a statutory body established by the Atomic Energy Act, initially the Atomic Energy Act of 1946 and subsequently by the Atomic Energy Act of 1954.

It was established for the purpose of insuring appropriate liaison between the Department of Defense and the Atomic Energy Commission.

Of course, you are fully aware that the Atomic Energy Commission has certain vital and important functions with which the Department of Defense has the greatest interest in that it is by law charged with the development of nuclear weapons or the use of nuclear energy for military as well as civilian purposes and charged also with the production of nuclear materials for use in military application.

With this important function assigned to the Atomic Energy Commission it is, of course, essential that the very closest liaison be maintained between the Department and the Commission in order to assure that the Commission may meet and does meet military requirements for the development of weapons and other applications of nuclear energy

I shall be happy to answer any questions as to how the organization is put together, what its functions are and how it performs those functions, satisfactorily or unsatisfactorily, as the case may be.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. Mr. Chairman, I have no questions at this point.

The CHAIRMAN. Mr. Fulton.

Mr. FULTON. We are glad to see you here, General Loper. I would like to ask you, Has the procedural and administrative setup of the Military Liaison Committee worked satisfactorily to date with the Atomic Energy Commission?

Mr. LOPER. I believe that it has. It has had the benefit of 11 years of experience, almost 12 years of experience.

Initially, of course, as with any new organizations, there were many flaws found in procedures and methods; questions as to relative authority arose and over the years, have been clarified by Presidential directives, agreements between the Commission and the Department of Defense, and by some changes in the law. So that it is my view, on the basis of about 6 years of rather close experience as, first, a service member of the Military Liaison Committee, and subsequently as Chairman, it has operated very effectively and quite to the satisfaction of both agencies concerned.

Mr FULTON. So that you as the representative of the Department of Defense and as Chairman of the Military Liaison Committee, would say the military development of weaponry systems has been adequately protected through the positions which you have held and the access you have obtained to the Atomic Energy Commission?

Mr. LOPER. Yes, sir; I would say that is right, Mr. Congressman.

Mr. FULTON. Have you any suggestions at the present time as to the current type of liaison—with yourself as Chairman, on the level of the Assistant Secretary of Defense, and the three major branches

APPROVED

September 1957

of the service being appointed in the discretion of the Secretary of Defense? Can you say how that has worked, or do you have other suggestions or recommendations?

Mr. LOPER. I think this organization is properly conceived and it operates well.

The members of the Military Liaison Committee are seven in number, the Chairman appointed by the President, with the consent of the Senate. The Chairman is responsibile to the Secretary of Defense.

The 6 military members are of flag and general officer rank appointed by the Secretaries of the services; 2 from each of the services with the consent of the Secretary of Defense.

All of these military members have key positions in the atomic energy field in their own services.

Mr. FULTON. At this point may we put in the record the extract from the Atomic Energy Act of 1954, section 27, the Military Liaison Committee.

Might I also refer the witness to the Department of Defense directive of October 5, 1954, setting up the Military Liaison Committee.

You know of that Department of Defense directive, do you not?

Mr. LOPER. Yes.

Mr. FULTON. And with the chairman's consent, may we put in the record the outline of the Department of Defense directive No. 5148.2 of October 5, 1954, covering that same thing.

May we also put in the charts showing the military nuclear power in conjunction with the AEC and the MLC in the Department of Defense, plus the basic research chart.

Then you have with you, do you not, the makeup of the administrative organization, the Military Liaison Committee of the Atomic Energy Commission?

Mr. LOPER. Yes, sir; I have a copy of this.

Mr. FULTON. We will put this in the record, too.

Then on the organization for military application of atomic energy I believe you have prepared a chart showing the relationship up to the President and the two branches of the Congress.

Mr. LOPER. That is correct.

Mr. FULTON. We will put that in the record.

Finally, a chart showing the establishment of the development requirement and military characteristics.

With the chairman's permission we will put that in the record.

Then you have a statement, I believe, do you not, on how the Military Liaison Committee was established pursuant to the act of 1954?

Mr. LOPER. I do.

Mr. FULTON. Will you submit that?

Mr. LOPER. Yes.

The CHAIRMAN. Without objection, it is so ordered.

(The material referred to is as follows:)

EXTRACT FROM ATOMIC ENERGY ACT OF 1954

SEC. 27. MILITARY LIAISON COMMITTEE.—There is hereby established a Military Liaison Committee consisting of—

a. A Chairman, who shall be the head thereof and who shall be appointed by the President, by and with the advice and consent of the Senate, who shall serve at the pleasure of the President, and who shall receive compensation at the rate prescribed for an Assistant Secretary of Defense; and

b. A representative or representatives from each of the Departments of the Army, Navy, and Air Force, in equal numbers, as determined by the Secretary of Defense, to be assigned from each Department of the Secretary thereof, and who will serve without additional compensation.

The Chairman of the Committee may designate one of the members of the Committee as Acting Chairman to act during his absence. The Commission shall advise and consult with the Department of Defense, through the Committee, on all atomic energy matters which the Department of Defense deems to relate to military applications of atomic weapons or atomic energy including the development, manufacture, use, and storage of atomic weapons, the allocation of special nuclear material for military research, and the control of information relating to the manufacture or utilization of atomic weapons, and shall keep the Department of Defense, through the Committee, fully and currently informed of all such matters before the Commission The Department of Defense, through the Committee, shall keep the Commission fully and currently informed on all matters within the Department of Defense which the Commission deems to relate to the development or application of atomic energy The Department of Defense, through the Committee, shall have the authority to make written recommendations to the Commission from time to time on matters relating to military applications of atomic energy as the Department of Defense may deem appropriate. If the Department of Defense at any time concludes that any request, action, proposed action, or failure to act on the part of the Commission is adverse to the responsibilities of the Department of Defense, the Secretary of Defense shall refer the matter to the President whose decision shall be final.

October 5, 1954
No. 5148.1

Department of Defense Directive

Subject. Military Liaison Committee.

I Purpose

It is the purpose of this directive to define the authority and duties of the Military Liaison Committee (hereinafter called the "Committee") and to define the relationships of the Committee with the military departments and other agencies of the Department of Defense, and with the Atomic Energy Commission (hereinafter called the "Commission").

II. Authority for issuance

This directive is issued pursuant to the Atomic Energy Act of 1954 (hereinafter called the "act") which establishes the Military Liaison Committee and the authority vested in the Secretary of Defense by the National Security Act of 1947, as amended, and modified by Reorganization Plan No. 6 of 1953.

III Directive superseded

This directive supersedes Department of Defense Directive No. 5148.1. Subject: Military Liaison Committee, dated April 13, 1953.

IV Membership of the committee

The Committee shall consist of:

A A Chairman who is the head thereof and who is appointed by the President as provided for in the act

B Two members from each of the military departments to be assigned by the Secretary of the respective departments after consultation with the Chairman. These members shall normally be of general or flag officer rank and shall be authorized to represent their departments on matters before the Committee.

V Committee staff

A The Committee shall be provided with a staff of military and civilian personnel as approved by the Secretary of Defense.

B The staff shall be headed by an executive secretary who shall be specifically designated by the Chairman This position will normally be occupied by a brigadier general or equivalent and rotated among the three military departments.

C Military personnel shall be detailed to the staff of the Committee by the Office of the Secretary of Defense in approximately equal numbers from each of the three military departments and shall be acceptable to and serve at the pleasure

of the Chairman. During their tenure on the Committee staff, such personnel shall be responsible to the Chairman for the performance of duty. They shall not be transferred or reassigned except after reasonable notice in advance to the Chairman through the Office of the Secretary of Defense so that suitable replacements may be obtained.

D. Civilian personnel for the staff shall be provided by the Office of the Secretary of Defense.

VI. Committee functions and authority

A. The Committee, on behalf of the Department of Defense and in accordance with the provisions of Section 27 of the act, shall advise and consult with the Commission on all atomic energy matters which the Committee, acting for the Department of Defense, deems to relate to military applications of atomic weapons or atomic energy, including the development, manufacture, use and storage of atomic weapons, the allocation of special nuclear material for military research, and the control of information relating to the manufacture or utilization of atomic weapons

B. The Committee shall keep the Secretary of Defense and other appropriate agencies of the Department of Defense fully and currently informed on all matters set forth in VI A above.

C. The Committee, acting for the Department of Defense, shall keep the Commission fully and currently informed on all matters within the Department of Defense which the Commission deems to relate to the development or application of atomic energy.

D. If the Committee at any time concludes that any request, action, proposed action, or failure to act on the part of the Commission is adverse to the responsibilities of the Department of Defense, the Committee shall make such recommendations to the Secretary of Defense as it deems appropriate.

E. The Committee shall be the channel of formal communciation between the Department of Defense and the Atomic Energy Commission, but in the exercise of its liaison function it shall encourage and facilitate informal contacts between agencies of the Department of Defense and the Commission at corresponding levels.

F. In the exercise of the functions and authority prescribed herein the Committee shall not assume the functions and authority of other established agencies of the Department of Defense as provided by appropriate directives.

VII. Procedures

A. The Committee is authorized to establish committees, councils, boards, or assignments as necessary to obtain information and carry out the functions and responsibilities of the Committee.

B. The Committee shall meet at the call of its Chairman or at such times as it may fix, and the presence of the Chairman (or acting Chairman) and three military members, including at least one representative of each department, shall constitute a quorum. Members and Chairman each have equal voting power. If any member dissents on any Committee action, he is authorized to appeal to the Secretary of Defense through the Secretary of the Department he represents. Prior notification of any such action shall be made to the Chairman and other members of the Committee Final action on appealed cases will await decision of the Secretary of Defense.

C. The Committee shall establish its own rules of procedure

C. E. Wilson, *Secretary of Defense.*

October 5, 1954
No. 5148 2

DEPARTMENT OF DEFENSE DIRECTIVE

Subject: Responsibilities of Assistant to the Secretary of Defense (Atomic Energy).

Pursuant to the authority vested in me by the National Security Act of 1947, as amended, and modified by Reorganization Plan No 6 of 1953, a position of Assistant to the Secretary of Defense (Atomic Energy) is hereby reestablished At the discretion of the Secretary of Defense, the Chairman of the Military Liaison Committee may also be appointed to serve as the Assistant to the Secre-

tary (Atomic Energy) without additional compensation. The Assistant to the Secretary (Atomic Energy) shall:

1 Provide the Secretary of Defense and principal members of his staff advice and assistance on atomic energy aspects of Department of Defense policies, plans and programs.

2. Formulate atomic energy policies, plans and programs for the Department of Defense, and monitor compliance with approved policies.

3. Represent or arrange for the representation of the Department of Defense with other governmental, nongovernmental and international organizations on atomic energy matters of mutual interest or responsibility.

4 Formulate policies for the transmission of information to the Joint Committee on Atomic Energy as required by the Atomic Energy Act of 1954, and coordinate such information, where appropriate, with other offices and agencies of the Department and with the Chairman of the Atomic Energy Commission

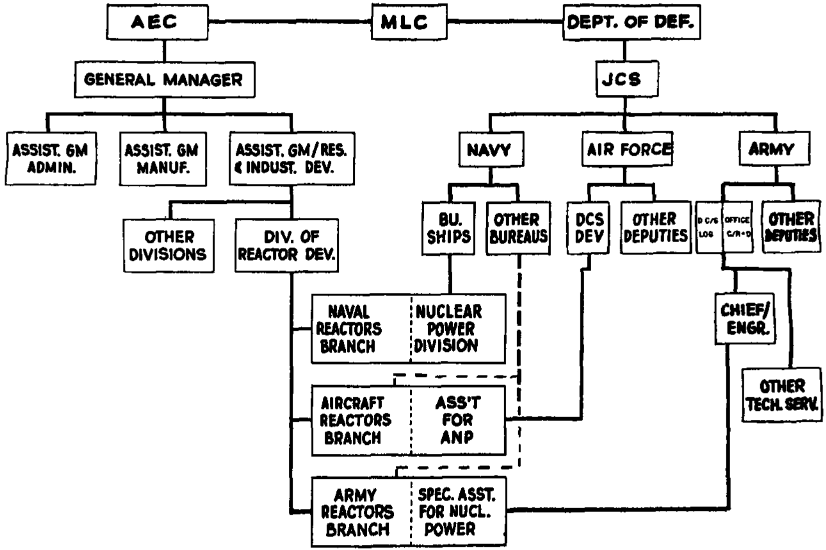
In the performance of these functions the Assistant to the Secretary (Atomic Energy) will by direct access, to the extent necessary and appropriate, utilize the advice, assistance and facilities of the Armed Forces Special Weapons Project, and of other organizations of the Department of Defense (including the three military departments) which are concerned with military application of atomic energy, in lieu of providing for such assistance on his immediate staff, but this arrangement shall not be construed or so utilized as to circumvent the normal command channels through the Secretaries of the military departments for the formal communication of approved policies, plans or other directives.

The Military Liaison Committee, established by the Atomic Energy Act of 1954, shall advise the Assistant to the Secretary of Defense on such atomic energy matters as the latter deems appropriate and necessary.

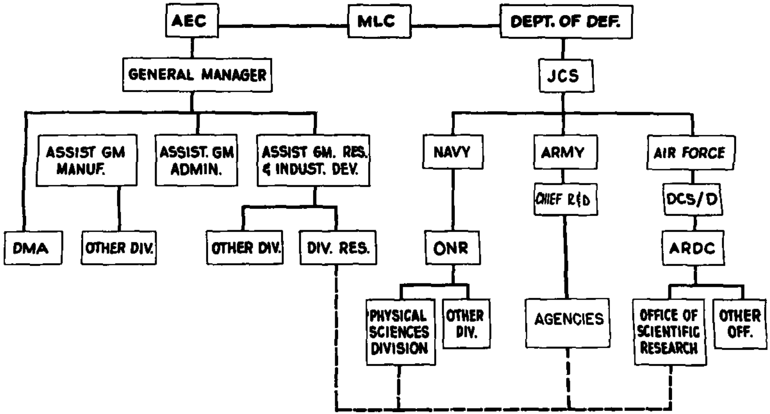
This directive supersedes Department of Defense Directive 5148.2, dated April 13, 1953.

C E. WILSON,
Secretary of Defense.

MILITARY NUCLEAR POWER

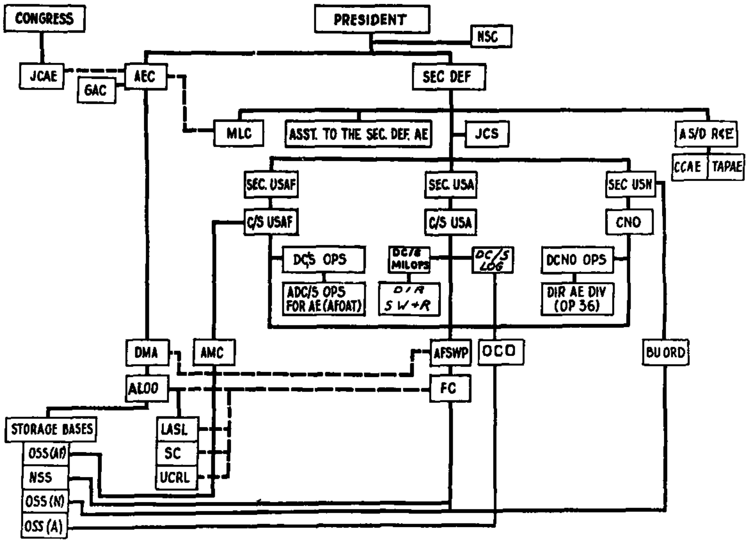


BASIC RESEARCH

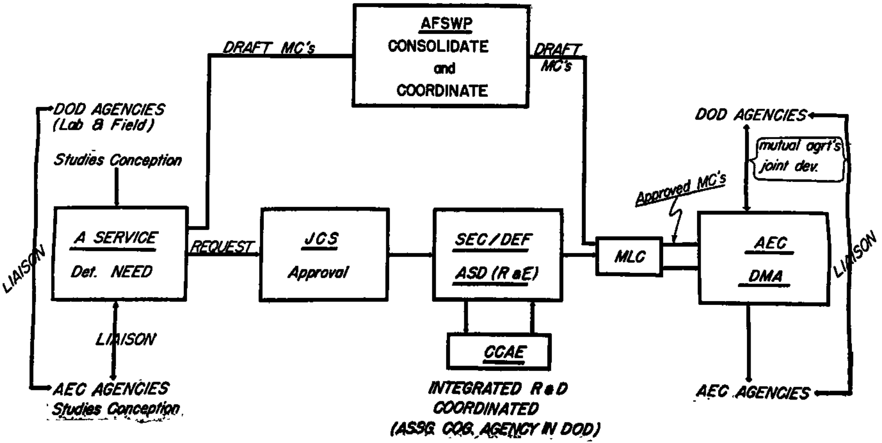


JOINT ONR-AEC NUCLEAR PHYSICS BASIC RESEARCH PROGRAM IS COORDINATED AS SHOWN IN DOTTED LINES ABOVE WITH AEC, NAVY, ARMY, AIR FORCE (ALSO WITH NATIONAL SCIENCE FOUNDATION)

Organization for Military Application of Atomic Energy...



ESTABLISHMENT OF DEVELOPMENT REQUIREMENT AND MILITARY CHARACTERISTICS



The Military Liaison Committee

The Military Liaison Committee, established pursuant to section 27 of the Atomic Energy Act of 1954, consists of a Chairman, appointed by the President as provided for in the act, and two members each from the Departments of the Army, Navy, and Air Force. The Chairman is also Assistant to the Secretary of Defense (Atomic Energy), holding that position at the discretion of the Secretary of Defense. The members, of flag or general officer rank, occupy key positions and have extensive responsibilities in the field of atomic energy within their departments, a fact which is very beneficial to the functioning of the Committee. The members represent their departments on all Committee business. Their assignments are as follows:

Department of the Army:
- Director, Special Weapons, Office of Chief of Research and Development.
- Director, Special Weapons and Requirements, Office of Deputy Chief of Staff for Military Operations.

Department of the Navy:
- Director, Air Warfare Division, Office of Deputy Chief of Naval Operations (Air).
- Director, Atomic Energy Division, Office of Deputy Chief of Naval Operations (Fleet Operations and Readiness).

Department of the Air Force.
- Assistant Deputy Chief of Staff, Development.
- Assistant for Atomic Energy, Office of Deputy Chief of Staff, Operations

Two additional key officials in the field of atomic energy who serve with the Committee in the capacity of observers are the Chief, Armed Forces Special Weapons Project, and the Director, Division of Military Application, Atomic Energy Commission.

The military staff of the Committee, consisting of 12 officers headed by the executive secretary, is located with the headquarters of the Atomic Energy Commission and is organized into five divisions: Administrative, Materials Production, Nuclear Power, Special Projects, and Weapons.

The Committee, on behalf of the Department of Defense and in accordance with the provisions of section 27 of the act, advises and consults with the Commission on all atomic energy matters which the Committee, acting for the Department of Defense, deems to relate to military application of atomic weapons or atomic energy, including the development, manufacture, use and storage of atomic weapons, the allocation of special nuclear material for military research, and the control of information relating to the manufacture or utilization of atomic weapons. With respect to atomic energy matters relating to military application of atomic weapons or atomic energy, the Committee keeps the Secretary of Defense and other appropriate agencies of the DOD fully and currently informed. The Committee, acting for the DOD, also keeps the Commission fully and currently informed on all matters within the Department of Defense which the Commission deems to relate to the development or application of atomic energy.

In accordance with the Department of Defense directive defining the authority and duties of the Military Liaison Committee, the Committee is the channel of formal communication between the DOD and the AEC However, in exercising liaison functions, the Committee encourages and facilitates informal contacts between agencies of the DOD and the Commission at corresponding levels.

THE MILITARY LIAISON COMMITTEE

Members:
- Hon. Herbert B Loper, Chairman
- Maj. Gen. John S. Mills, United States Air Force, Assistant Deputy Chief of Staff, Development, United States Air Force
- Maj. Gen. John P. Daley, United States Army, Director, Special Weapons, Office of the Chief of Research and Development, United States Army
- Maj. Gen. Richard T Coiner, Jr, United States Air Force, Assistant for Atomic Energy, Office of Deputy Chief of Staff, Operations, United States Air Force
- Maj. Gen Dwight E. Beach, United States Army, Director, Special Weapons and Requirements, Office of the Deputy Chief of Staff for Military Operations, United States Army
- Capt. Joseph D. Black, United States Navy, Director, Air Warfare Division, Office of the Chief of Naval Operations, United States Navy
- Capt. Joseph A. Jaap, United States Navy, Director, Atomic Energy Division, Office of the Chief of Naval Operations, United States Navy

Observers
Rear Adm. Edward N. Parker, United States Navy, Chief, Armed Forces Special Weapons Project
Brig. Gen. Alfred D. Starbird, United States Army, Director, Military Application, Atomic Energy Commission

Mr. FULTON. Has the present organizational setup of the Military Liaison Committee worked well in protecting the military programs of the Department of Defense in connection with the Atomic Energy Commission? When we are entering a new field called the space field, which will use many kinds of propellents for space vehicles and missiles, including nuclear and atomic energy, would you recommend the same kind of organizational setup for a military liaison committee to the National Space Agency that we propose by this legislation?

Mr. LOPER. Without making considerably more study of the relationships which may be necessary, I could not recommend it offhand.

I would say if the situations are analogous, then an analogous solution would be a fine one.

Mr. FULTON. Have you read the proposed legislation?

Mr. LOPER. I have read the proposed legislation. I have not had an opportunity to study it and to grasp in my own mind just what the relationship between the space agency and the Department of Defense is intended to be, or would be.

Mr. FULTON. Our problem is the method of setting up the relationships between the Department of Defense and the NASA as proposed, as well as the AEC.

The question is: If the NASA agency that is proposed is to be a civilian agency just as the Atomic Energy Commission has been, then what should the military liaison setup be?

Now, you have had the most experience on that Military Liaison Committee with a similar type of agency in a different field. We, therefore, would like to have inserted in the record, if you are not ready at this time, your considered judgment of, first, how the Military Liaison Committee has acted with the AEC, and, secondly, how it would be set up in conjunction with the current bill that has been entered by Congressman McCormack of Massachusetts.

And, thirdly, I would like to know what your recommendations would be on the Military Liaison Committee in conjunction with an Atomic Energy Commission type setup of five members for the National Space Agency that is proposed.

That is, transposing the successful method which has already been used on atomic energy to the space field.

Mr. LOPER. I will try to answer it in part. I would say that offhand it does not appear to me that the situations are strictly analogous and, therefore, the same solution might not be best.

Certainly, an effective type of liaison between two agencies would be necessary. Whether the same type would be right, I think would depend on the greater refinement of the respective fields of coverage in the production and operation in the research areas.

Mr. FULTON. Would you have the Military Liaison Committee have representatives of the three services, the Army, Navy, and Air Force, as I believe you have now?

Mr. LOPER. I believe this is correct. I believe it would be necessary, each one having certain functions and operations even though they might be of a service nature in the space business.

Mr. FULTON. How big a committee would you have as a military liaison committee to the National Space Agency if it is a commission of five members?

Mr. LOPER. It should not be any larger than we have

Mr. FULTON. How many members?

Mr. LOPER. We have a total of seven, including the Chairman.

Mr. FULTON. Would you again have a military person as chairman of the military liaison committee for the space agency and place that person on the level of the Assistant Secretary of Defense?

Mr. LOPER. I think it ought to be on that level I don't believe it is essential that it be an active military officer.

As you know, the present Atomic Energy Act provides that the Chairman of the Committee may be an active officer of one of the military services, a retired officer or a civilian. We have had all three.

Initially the Chairman was an active military officer for the first couple of years, then we had civilians for a good many years.

I, myself, who went on the job 4 years ago, am a retired military officer. I do not say that one could recommend one over the other.

I think the position in the Department of Defense should be at least that of the Assistant Secretary of Defense level.

Mr. FULTON. Inherent in my question was the possibility that we might in the legislation limit it to an active military person.

Mr. LOPER. A wise move, depending again somewhat on the composition of the space organization.

Mr. FULTON. Generally you would not limit it to that.

Mr. LOPER. I don't believe I would limit it. There is a point of difference here which I think you recognize in considering the organization of the Atomic Energy Commission in that the law does require they maintain a Division of Military Application, which is headed by an active military officer.

Their Division of Military Application Chief is selected from the active ranks of the service.

Mr. FULTON. And he is right under the Atomic Energy Commission?

Mr. LOPER. Yes, sir; his total loyalty is to the Atomic Energy Commission.

Mr. FULTON. Subject to their discretion and control?

Mr. LOPER. Exactly, and subject to their hiring and firing and any time they are not pleased with him, of course, they may relieve him and choose another.

Mr. FULTON. Is his relationship with the Commission a military or civilian connection?

Mr. LOPER. It is civilian.

Mr. FULTON. Is he on inactive duty with the military services?

Mr. LOPER. No, sir; he is just on what you might call a leave of absence. He has no military command or assignment of any kind.

Mr. FULTON. What other military personnel might have been assigned such as he has under him in the Atomic Energy Commission?

Mr. LOPER. He has a military and civilian staff. I would say his local staff in Washington is about half military, who are assigned at their request from military services, and half civilian.

Mr. FULTON. Would you give us the name of the individual currently holding the position, and also the number of civilians and military personnel on the staff?

Mr. LOPER. I do not know the number on his staff. The officer, however, is Brigadier General Starbird, Alfred D. Starbird.

Mr. FULTON. Where is he from?

Mr. LOPER. He is a Corps of Engineers officer in the Army.

Mr. FULTON. Would you at this point in the record put in the organizational setup in general?

Mr. LOPER. Yes, sir; I will give you an organizational chart for the Director of Military Applications.

Mr. FULTON. And also the functions assigned to him by the Atomic Energy Commission.

Mr. LOPER. I shall be glad to do that.

(The information referred to is on p. 847.)

Mr. FULTON. Moving a bit further, the question comes up when we are on dangerous missions such as space flights are to be, should there be special incentive pay for military personnel who undertaken these dangerous missions and missions of peculiar hardship with unknown risks?

Mr. LOPER. I would certainly think so.

Mr. FULTON. Would you recommend to this committee that we enter the fi ·ld or recommend that there be special consideration given on dangerous type military services—possibly where the chances become large on many of these manned vehicles on the original flight, should we not have fifty or one hundred thousand dollars worth of coverage of insurance for the man?

Mr. LOPER. Certainly, some emolument of that type ought to be provided.

This is a tremendous risk, of course.

Mr. FULTON. So that you would recommend that there be separate hazard pay as well as insurance to cover the family for military personnel engaged or lent to this agency for the experimental manned space vehicle flight?

Mr. LOPER. I would certainly recommend that; yes.

Mr. FULTON. Would you rather have a director who is a czar of a program such as the space development, with an advisory committee of 17 members, or would you prefer a setup secondly, that had a 5-man commission organized along the lines of the Atomic Energy Commission?

Mr. LOPER. I would prefer a single director.

Mr. FULTON. How would you set the advisory committee up in that event, and what size should it be, and what powers should it have?

Mr. LOPER. I would not want to suggest what size the advisory committee should be, because I have not tried to visualize the number of interests of a scientific, technical, political, psychological and other nature, which would need some special consideration by an advisory committee.

I think, however, that a committee along the lines of the General Advisory Committee for the Atomic Energy Commission meeting at frequent intervals would be a desirable setup.

Mr. FULTON. Do you think that a voluntary or part-time committee would be adequate in as important a field, where there are so many lines of research to be made as the space field?

Mr. LOPER. I believe there would be.

Mr. FULTON. Would you transpose pretty much the same advisory committee from the NACA?

Mr. LOPER. Yes, sir.

Mr. FULTON. The Advisory Committee for Aeronautics?

Mr. LOPER. Yes.

Mr. FULTON. Would you emphasize people who are currently engaged, either commercially or in the form of military officers, that have had air or aeronautic experience, or would you be more for the scientific and adventurous type of person?

Mr. LOPER. I think you need both for balance.

Mr. FULTON. Then why, if you select a director, should you not look for a balance on a commission such as a man who is knowledgeable on astronomy to begin with, say a man knowledgeable on vehicles and construction; a man knowledgeable on propellents, a man knowledgeable on nuclear atomic power and a man knowledgeable on a public approach with some financial and business background?

Why could you not, while looking around for people of specific talent combine them in a better working organization in a combination of five, than you would have if you had a director or czar. Then you would have to decide whether he was a businessman, officeholder, military man, scientist, or administrator?

Mr. LOPER. My general opposition to commissions as directors of active programs is that individually they cannot keep their fingers out of the operating end of it, if they are full time.

If they know everything that is going on down to a lot of the field operating details, they are inclined to attempt to make those directly rather than through the man they have hired for the job.

Mr. FULTON. Suppose a commission of five should set up an office of director, or Congress set up an office of director which was approved by the Senate, would that assist you in getting some sort of modified type of organization—one that would combine both the features of a director and the commission such as the Atomic Energy Commission?

Mr. LOPER. This might be useful. Under the present Atomic Energy Act the General Manager has certain functions which may be delegated to him by law. The law permits certain functions to be delegated to the General Manager.

It is silent on other functions, leaving the Commission to decide what other functions they may delegate or they wish to delegate, and also whether they wish to delegate those functions which the law forces them to do. The result is that some functions are delegated to the General Manager to perform without direct instructions. Many others are not.

It has been my experience that this variation in delegating authorities to an operating manager leaves him at a total loss as to how to proceed. He can proceed on somewhat minor things which may be delegated to him in a day-to-day operation and find himself running crosswise with one or more of his Commissioners.

Mr. FULTON. Will you put in the record at this point your ideas on these functions of various suggestions which I have made, so that we will not go into them in too much detail here?

Mr. LOPER. Yes, sir.

(The material referred to follows:)

DEPARTMENT OF DEFENSE,
MILITARY LIAISON COMMITTEE,
Washington, D. C, May 13, 1958.

DEAR MR. CHAIRMAN: In response to a committee request during the hearing of April 28, 1958, I am forwarding my personal views concerning the commission-

type organization However, I suggest that the Atomic Energy Commission itself might be a better source of information concerning the details of operation under this form of organization.

It is my feeling that an operating program can be far more effectively managed and directed by a single manager or director than by a commission. Scientific advice and guidance is desirable, of course, and may be furnished by a committee similar to the General Advisory Committee to the Atomic Energy Commission. However, the decision making authority and the responsibility for execution of a program should be lodged in an individual In the commission form of organization, the day-to-day operation becomes cumbersome It is difficult to reach timely decisions and responsibility for successful and efficient operation may be divided. The manager, who must operate under whatever authority has been delegated to him by the commission, may frequently be hampered by having to wait for commission deliberations and decisions

Sincerely yours,

HERBERT B. LOPER, *Chairman.*

Mr. FULTON. Lastly, I want to ask you· Do you favor more the Manhattan-type project with a General Groves in charge than the development of an Atomic Energy Commission as a civilian agency, as it historically developed?

Mr. LOPER. No; for the purpose for which it was established, which was a wartime crash program for the development of atomic energy for a specific purpose, I believe the Manhattan project was a superior type of organization. When it entered into broader fields, then I think civilian control was quite the proper thing to do.

Mr. FULTON. As this Agency is now proposed, it is to enter into the broader field, so you would then recommend a civilian-type agency.

Mr. LOPER. Yes; but my question is whether this civilian-type agency should be headed by a Director and with the general supervision of a board of directors, headed by a chairman, or whether it should be an operating agency under the direct operation of a commission.

My feeling is that it should be the former.

Mr. FULTON. Would you have it as an advisory or as an operating group?

Mr. LOPER. I think it can be more than advisory. I think that it could establish certain basic policies.

An advisory committee formula does not have the function of really establishing policies It is only when they come to the actual implementation of policies which have been established that I find the commission-type of control to be at least cumbersome

Mr FULTON But you would have this particular National Space Agency set under Congress' supervision and operate the national policy for space, would you not?

Mr. LOPER That is right.

Mr. FULTON Secondly, then, in the operations you would have the new Columbus of 1958 start out, directed, controlled, and operated by the National Space Agency, would you not?

Mr. LOPER Yes, sir.

When one speaks of operation, though, directly controlled and operated, to me that implies that they take part in the day-by-day management of the business.

Now, this is the part that I find to be cumbersome from a commission operation standpoint.

Mr. FULTON. Do you feel, at present, there should be a large expansion of the space research exploration, development of missile and vehicle programs?

Mr. LOPER. I do not believe there should be a large expansion until there are large numbers of ideas and areas which show promise of exploration, of fruitful exploration.

I do not believe in expansion just for expansion's sake, but where there are large numbers of apparently, or possibly advantageous areas that we should look into, then certainly an agency should be available to do this.

Mr. FULTON. My last question is this:

You would favor von Braun's 150-mile shot of man in space; would you not? And you would not consider that like shooting a woman out of a cannon?

Mr. LOPER. No, sir; not at all

Mr. FULTON. What do you consider it?

Mr. LOPER. Frankly, I do not see much merit shooting a man 150 miles into space just to shoot a man into space 150 miles.

Mr. FULTON. Is that program worthwhile? That is a very disputed question before this committee. What would you say about it?

The CHAIRMAN. Von Braun did not say he was just shooting a man into space. He said he would be up there 5 or 6 minutes and would supply information that is available.

Mr. LOPER That is right. If it is a step in the right direction, and I assume it has been thought out by Dr. von Braun, a step in the direction of the useful navigation of space, and a necessary step in that direction, then it is the right thing to do.

Mr. FULTON. He thought it should be, but there were some scientists who felt it should not be.

Thank you; that is all.

The CHAIRMAN. Mr. McDonough, do you have some questions?

Mr. MCDONOUGH. In reference to this question of shooting a man into space, there has been much ridiculous talk about it. Personally, I think it would reveal a lot of scientific information we do not have.

The CHAIRMAN. I might say that the gentleman is here for a limited purpose in connection with the organization

Mr. MCDONOUGH. Yes; but I want to consider the matter. It may reveal a great deal of information concerning the effect on man, the reentry problems of heat and landing and the ability actually to project a man a distance into space.

Do you now agree that that would be necessary information for us to have?

Mr. LOPER. If we are contemplating, as I am sure we are contemplating, some type of outer space travel by humans, then, of course, it has to be approached step by step to determine just the thing that you have mentioned, sir.

As I say, if Dr. von Braun's proposition is an essential step on that road, then it is the proper thing to do.

Mr. MCDONOUGH. In your connection with the Atomic Energy Commission, are you there for the purpose of liaison of the Defense Department for military observation, or for any civilian development that they may reveal in their investigations?

Mr. LOPER. Well, there is a close tie-in between civilian military applications, particularly in reactors for propulsion versus reactors for stationary power.

In the medical and biological areas, what applies to civilians also applies to military. So as a Military Liaison Committee we do keep

ourselves acquainted with their civilian-type projects to determine what interest they are to us, what is being learned from them, and how they may be applied to Defense Department business.

Mr. McDonough. Do you envisage this Agency that we are considering here in this bill as more in the interest of civilian than military development?

Mr. Loper. It would appear to me that at least for a good many years its interest will be primarily in military development, because this is where we are now, and the space business is primarily for determining the value of movement in or the occupation of space for military purposes.

In the long run it is difficult for me to say. I could not project myself into the future far enough to say whether these interests will be more in the military line or more in the civilian or peaceful line.

I would certainly hope that it would be more in the civilian applications.

The Chairman. That depends a lot on world conditions?

Mr. Loper. Yes, sir. This depends on things outside our ken at the moment.

Mr. McDonough. In other words, as we develop military uses of outer space and travel and communications, the byproduct of that for civilian development will come as a natural consequence.

Mr Loper. It has always happened this way, of course; many developments which we have undertaken on an urgent basis for military purposes have broadened themselves into civilian applications.

Mr. McDonough. Do you think the Agency should be limited in its operating authority to basic research or should it go beyond that?

Mr. Loper. I have not studied that part. As a matter of fact, I have given very little thought to that because I am extremely busy on other things, and space matters do not come into my field except as it touches on the business between the military department and the Atomic Energy Commission, on which I effect liaison.

Some place in the civilian aspects of this there must be space for more than just basic research, it seems to me. Therefore, if you have a Space Agency as a civilian organization, its functions, to my mind, should not be limited to basic research.

The Chairman. Mr. Keating.

Mr. Keating. General Loper, I realize you were called here for a specific purpose to discuss this Military Liaison Committee, but you have been asked a lot of other questions and there is one matter among those that I want to clear up

This recommendation you made for more pay for the military involved in space work, does that have clearance from the Department of Defense?

Mr. Loper. Not at all.

Mr. Keating. You are only speaking as an individual?

Mr. Loper. I am speaking entirely as an individual giving an opinion that if you want to get useful work out of people of this type, you had better pay them well for it whether they be civilians or military people.

Mr. Keating. You have in the Department of Defense others engaged in hazardous work who do not get extra pay now?

Mr. Loper. I think that is right. There is some hazardous pay being paid, but you have a great many people who do not get it.

Mr. KEATING. When you enlarge the activity of those who are to get extra pay you run into competition always in the Department of Defense?

Mr. LOPER. That is right.

Mr. KEATING. I would not want to have it appear here that your recommendation was a Department of Defense recommendation.

Mr. LOPER. Clearly not.

Mr. KEATING. With regard to the Military Liaison Committee this was set up in the Atomic Energy Act of 1954.

Mr. LOPER. Yes, sir; initially in the first Atomic Energy Act of 1946.

Mr. KEATING. Did the act of 1946 have the same setup as the 1954 act?

Mr. LOPER. Yes, sir.

Mr. KEATING. In other words, the section 27 that you have put in the record here from the act of 1954 was practically verbatim in the 1946 act?

Mr. LOPER. It is about the same. There have been some changes in the wording, but no changes in the actual functions.

Mr. KEATING. One of our problems here is whether to set up some liaison arrangement in the act in detail, or to leave it to general language. We all agree there should be liaison between military and civilian.

Do you have any views as to whether it is better to set up general language and leave it to the administrators of the Defense Department, or Space Agency, to work out details, or set up the details of that Military Liaison Committee in the law at the outset.

Mr. LOPER. I believe there should be general language.

The CHAIRMAN. Suppose he does not do it that way. It is discretionary. Suppose he decides to appoint a liaison committee.

Mr. LOPER. I would not make it discretionary.

Mr. KEATING. You say there shall be liaison between the two, but more or less leave it to them to set up the method of liaison?

Mr. LOPER. Yes, sir.

Mr. KEATING That is all, Mr. Chairman.

Mr. FULTON. May I ask another question?

The CHAIRMAN. Yes, Mr. Fulton.

Mr. FULTON. Your views here as a witness are those that have come to you as you sit in a rather informal discussion, and you have not limited yourself solely to views which have previously been cleared by the Department of Defense and the Atomic Energy Commission?

Mr. LOPER. This is correct. These are my personal views, speaking entirely and trying to be as helpful as I can to this committee, in considering this very important question.

Mr. FULTON. I might say my questions were not intended to bind you on your views, but to explore how we might better set up a program.

The CHAIRMAN. Mr. Secretary, how has the Liaison Committee setup in the AEC worked?

Mr. LOPER. I think it has worked very well. I do not want to give myself any plaudits on this as Chairman of it, but I believe the concept and the operation of the Committee has been entirely satisfactory.

The CHAIRMAN. In an activity where there is dual responsibility, one civilian and the other military, where the exigencies of the military cannot be ignored, but must be given proper emphasis, such a committee might in operation obviate rigidity in the law and try to set forth in detail what their functions would be. It would allow more flexibility.

Mr. LOPER. Yes, sir; this is right Initially I said if the situations are analogous, then the solution should be approximately the same.

I just do not quite see that we have an analogous situation, therefore, I make no specific recommendation as to whether one should have or should not have a military liaison committee.

In the relationship between the Atomic Energy Commission and the Department of Defense, one must keep in mind that the Atomic Energy Commission does perform a specific military function in that it designs and builds weapons for the Department of Defense. It does not do it as a contractor to the Department of Defense, but as a separate Government entity or agency—this making it, I think, quite appropriate that a formal liaison be established, as well as the somewhat peculiar organization of the Commission in having a Director of Military Applications assigned to it from the military services.

It is not apparent to me from what I have heard heretofore of the proposed act that the same situation necessarily exists between the Space Agency and the Department of Defense in this subject.

The CHAIRMAN. Mr. Feldman.

Mr. FELDMAN. In response to a question put to you by Congressman Keating, you said you would prefer general language to be used in connection with describing the duties of a liaison committee.

Would you say that language similar to the language contained in the Atomic Energy Act of 1954 was general in character?

Mr. LOPER. I think that is general language because our own directives go much further than this in the actual organization.

Mr. FELDMAN. That is what you had in mind when you answered his question; is that right?

Mr. LOPER. That is right.

Mr. KEATING. Would you yield at that point?

Mr. FELDMAN. Yes.

Mr. KEATING. That clearly was not my understanding of your answer, General Loper. I put to you this question:

Should we just say there shall be liaison and you said you favored something along that line. This section 27 sets up the method of effecting that liaison, does it not?

Mr. LOPER In part, it does; it gives the broad functions of the Committee which I believe should be specified in the law.

Mr. KEATING. I thought you were not prepared to recommend whether there should be a committee?

Mr. LOPER. Well, if there is a committee——

Mr KEATING. Whether or not there is a committee there has to be liaison, has there not?

Mr. LOPER. That is right.

Mr. KEATING. So you do not know whether there should be a committee?

Mr. LOPER. That is correct. I do not know whether there should be.

Mr. KEATING. If there is not a committee, then this language would not be appropriate?

Mr. LOPER. That is right.

Mr. KEATING. Then we have to decide if there must be such a committee before you would say this language was appropriate?

Mr. LOPER. My point is this: if you do have a committee, the functions of the Committee should be specified in the law and thus become binding on both agencies, not to be decided by arrangement between them.

When I said it should not be on detail, I had in mind how it is organized and operates.

For example, I do not think it is necessary to specify that there shall be two members from each of the services. This I think is a detail which could be left out.

Mr. KEATING. It says representatives from each of the Departments of the Army, Air Force, and Navy in equal numbers should be appointed by the Secretary of Defense in this work.

Mr. LOPER. That is right. When I agreed with the counsel it should be along the lines of section 27 of the act of 1954, I had in mind not that it specified actual membership, but know how it performs its functions.

The CHAIRMAN. You might say there shall be three representatives, but not designating what services they came from, leaving it to the Secretary of Defense.

Mr. LOPER. I think that would be a reasonable thing to do, sir.

Mr. KEATING. You believe we first must decide that such a military liaison committee is necessary in the Department of Defense rather than in the Space Agency before we can set up anything like this provision in the Atomic Energy Act?

Mr. LOPER. Yes, sir; I think the first decision is whether the relationship between the two is such as to require a formal statutory liaison.

Mr. KEATING. On that you have no opinion?

Mr. LOPER. I have no opinion on this.

Mr. KEATING. Certainly unless we have a firm opinion, it would be better for this committee to provide in general there shall be liaison between military and civilian.

Mr. LOPER. That is right. If the committee is undecided as to the importance of it, that is all.

The CHAIRMAN. You do say the Liaison Committee has worked effectively with the AEC?

Mr. LOPER. That is right.

The CHAIRMAN. As I understood you, you said the Liaison Committee would be important in connection with this new agency.

Mr. LOPER. Liaison is very important. Whether it should be a formal committee or established as between the two——

The CHAIRMAN. If we provided nothing it would be wise for the Director and the Defense Department to appoint one administratively.

Mr. LOPER. Yes.

Mr. FELDMAN. I understood you to say, General Loper, in response to a question by Congressman McDonough, that the primary emphasis of the new agency would be military in character because of the overlapping of many of the problems; is that right?

Mr. LOPER. I would say initially it would appear to me to be so.

Mr. FELDMAN. And it would probably continue for several years?

Mr. LOPER. I would think so.

Mr FELDMAN. So that liaison between the military and this new Space Agency would be very important; is that right, General Loper?

Mr. LOPER. It would be very important.

Again it depends on a very careful definition of what the functions are of each of the organizations.

Mr. FELDMAN. Could you describe, in as much detail as you can, how your liaison committee functions, starting with the policy board on top and how it seeps through the organization down to the low echelons?

Mr. LOPER. There are, perhaps, two main fields of interest There are a great many minor fields of interest The two major fields of interest are the study, design, development, and production of nuclear weapons, and, secondly, the development of nuclear power for military purposes.

Now, the concept of a military application may begin anywhere, as anyone knows. It may begin in the minds of a laboratory technician, or it may begin in the mind of a military officer or military group.

When this concept is developed to the point where a study needs to be made as to whether it is really technically feasible, we have our first formal communication on this subject between the Department of Defense and the Atomic Energy Commission.

This communication emanates from one of the services which has a major interest in a particular study. It will go to our Assistant Secretary of Defense for Research and Engineering, who will decide whether or not it appears to have sufficient merit to justify investigation If he thinks so, he then asks the Military Liaison Committee to see that such a study is initiated, and the Military Liaison Committee does set up this study as between the Atomic Energy Commission and the appropriate agencies of the Department of Defense.

A study will be reported out, favorably or unfavorably, either that this proposed development of a new weapon or a new application is sound or it is not

If it is decided that it is sound, then the Military Liaison Committee refers it back to the Atomic Energy Commission to develop the nuclear part of the proposed application, and to the appropriate service for development of the carrying or delivery system.

This has to do particularly with the weapon. If it is a reactor, it is the same way. It goes back to the Navy, Army, or Air Force for development of the nonnuclear parts of the system we are talking about.

This is the way in which we get our business started.

Mr. McDONOUGH. Will you yield at that point?

Mr. FELDMAN. Yes.

Mr. McDONOUGH. General Loper, would you authorize this Agency to enter into a licensing agreement with private industry for the development of some experiment into outer space, in the building of satellite spaceships, or the shooting of satellites?

Mr. LOPER. The particular arrangement that it makes with private industry would appear to be a matter of judgment. Whether it be by contract or by license or some other arrangement, I would not want to express a view without looking at the particular problem.

Mr. McDONOUGH. I mean in general, like the Atomic Energy Commission does at the present time?

Mr. LOPER. Yes, sir. They perform a great deal of work by contract or by an operational organization, such as General Electric, which operates their Hanford program, and so on. By license or by contract, or otherwise, does not appear, to me, to offer any difficulties?

Mr. FELDMAN. Is the liaison continuous or spasmodic?

Mr. LOPER. The liaison is continuous. We have a permanent military-liaison staff which lives with the headquarters of the Atomic Energy Commission, has day-to-day contact with various of its divisions. We have a permanent field organization which does not report directly to the Military Liaison Committee, but which is our agency for the preparation of technical reports, for working closely with all of the laboratories and the storage-site people.

This is the Armed Forces special-weapons project that you will see referred to on one of the charts here. It is established for this technical liaison, lower level liaison purpose, and it maintains its personnel at laboratories and other activities of the Commission where day-by-day technical-level liaison is necessary.

Mr. FELDMAN. For this liaison to function efficiently, it has to be continuous and work from day to day?

Mr. LOPER. That is right.

Mr. FELDMAN. I believe you testified not only as to broad policy which is established by your Committee, but, also, that which seeps down through the organization so that you keep a constant flow of information and liaison between the lower groups?

Mr. LOPER. That is correct.

Mr. FELDMAN. The purpose of the liaison is so that the right hand knows what the left hand is doing; is that not so?

Mr. LOPER. Yes, sir.

Mr. FELDMAN. Can a liaison work effectively if it just works spasmodically, say once a month, or six times a year?

Mr. LOPER. Not at all

Mr. FELDMAN. I have one last question. Since we have had testimony before this committee indicating that the new NASA might be primarily military in character, and, further, because of your response to Congressman McDonough about the military nature of the new Agency—why call it a civilian agency if it is to be military in character?

Mr. LOPER. Well, we have good basis for it. The work of the Atomic Energy Commission, I think one could say, over the past 12 years, has been at least 75 percent military work, yet we call it a civilian agency, and it is. So, I do not think the amount of work one does in one line or the other determines whether it should be civilian or military.

Mr. FELDMAN. Is there not a similarity between the atomic-energy setup and the new Agency? NACA primarily is engaged in military work. The new Agency will continue that work. The Atomic Energy Commission took over the Manhattan project, which was military in character, and has continued on, in a so-called civilian way, the work which had been started there. Is that not so?

Mr. LOPER. That is right; yes.

Mr. FELDMAN. Is it your opinion that the AEC setup is a successful one?

Mr. LOPER. Yes, sir.

Mr. FELDMAN. I suppose I should ask you the obvious question: Why not use the same pattern, since it has been a successful standard of measurement?

Mr. LOPER. I see no reason why one should not use the same pattern—that is, a civilian agency, to direct the broad policy dealing with the development of utilization of space. I am not saying the organization could not be improved for so doing. As I indicated, I believe a single director rather than a commission form, in my personal opinion, is a better way to get at it.

I certainly have no quarrel with the administration's view that this should be a civilian setup. Getting down to my particular area here, which is the liaison area, I would not, until I could see the work which each is to perform, I could not recommend to myself or anyone else whether anyone did or did not set up this type of liaison.

The CHAIRMAN. It says that this new Agency shall exercise control over aeronautical and space research and so forth, except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations. I recognize the importance of the military in the world today, at all times, but particularly today. Yet, under that language, would it not give the Defense Department a complete voice in determining to what extent the new civilian agency might operate? According to what you and others say, practically everything is peculiar to or primarily associated with weapons systems of our military operations today.

Mr. LOPER. I do not think so when you read herein—

in which case the Agency may act in cooperation with, or on behalf of, the Department of Defense.

The CHAIRMAN. Again, that is language where the Department of Defense permits them.

Mr. LOPER. We had some similar language in the Atomic Energy Act of 1954. We have had no difficulty with it at all. They have the primary voice in the development of nuclear weapons and in their production, and yet they offer no difficulties in dealing on an appropriate and equitable level of interest here

I think all you are trying to do with this language is to point out that, in those things dealing with military applications, the Department of Defense is the agency of primary interest. This seems to me, offhand, to be appropriate.

The CHAIRMAN. That word "except" is what attracts my attention. You say we give this new Agency broad powers.

Through the word "except" you take all the powers away from it practically unless the Defense Department says it is all right. It seems to me that that word "except" is very significant.

You could say this:

Insofar as such activities may be peculiar to, or primarily associated with, weapons, the agency may act in cooperation with, or on behalf of, the Department of Defense.

If words could be put in there it might take care of it, but I am concerned about the word "except."

Mr. KEATING. A school of thought has developed that because the present activities of space are more largely of military character than they are civilian, there is no need of a civilian agency here. You do not share that view, do you, General Loper?

Mr. LOPER. No, sir.

Mr. KEATING. You do not blame us for looking forward to the day when we can forget about the military applications of outer space and look forward only to the peaceful applications.

Mr. LOPER. Not at all.

Mr. KEATING. You recognize that those peaceful applications might, as in the case of the atomic energy, someday completely overshadow and exceed those military uses to which we have put those forces.

Mr. LOPER. I fervently join you in the hope that we can look forward with some confidence to exactly this.

The CHAIRMAN. That is only a hope for the time being?

Mr. LOPER. That is only a hope for the time being.

The CHAIRMAN. I think we understand the significance of your testimony and your state of mind, General Loper. I do not think there is much difference of opinion between you and the members of the committee as far as that goes.

Mr. LOPER. I am sure not. I just regret I have not been able to give this subject a great deal of attention, not being in my particular line of business. So I am speaking only of what comes out of a mind here based on a few years of experience in similar work.

The CHAIRMAN. Mr. Feldman wants to ask another question, sir.

Mr. FELDMAN. How do you envisage the relationship will be between atomic energy and outer space?

Mr. LOPER. Atomic energy we think has a very important contribution to make to propulsion systems which might be quite useful in outer space or power supplies for long voyages in outer space and certainly it has a very vital function to perform in that area.

Mr. FELDMAN. How would you draw a line between them?

Mr. LOPER. What right now, it seems to me, would be useful for outer space travel in the nuclear power area would be quite useful for military purposes.

In other words, at the present time from the military standpoint we are interested in the use of nuclear power for a good many things within and without the atmosphere.

Mr. FELDMAN. How would you draw that line?

Mr. LOPER. At the moment I do not see how one can draw that line.

The CHAIRMAN. That is where the liaison committee might come into effective operation; is that right?

Mr. LOPER. That is right.

What is useful, let us say, to propel something for peaceful purposes in outer space might be quite useful to propel the same thing or similar thing for military purposes in outer space.

So I do not think one can distinguish here.

Mr. FELDMAN. Earlier in your testimony you mentioned something about the Commissioners mixing in the operation of the Liaison Committee.

Mr. LOPER. No; not in the operation of the Military Liaison Committee. I was saying that the commission forms of control, in general, run into the problem of individual commissioners getting concerned with day-by-day operations, thus directly obstructing or slowing them up. This is particularly troublesome when one takes a reasonably routine or minor problem and you have to set it before the Commission and obtain a majority ruling on it, which obviously slows down business when one man could have said go ahead, or don't go ahead, as the case may be.

Mr. FELDMAN. Of course, that is a question of organization.

We have heard, for example, of people in business who take care of details—and the big problems take care of themselves; is that right?

Mr. LOPER. That is right. It is a matter of rare judgment required in deciding to what extent the director of an organization might proceed to do business.

The CHAIRMAN. Are there any further questions of General Loper?

For myself, as chairman of the committee, and for other members of the committee, I express our thanks.

Mr. LOPER. It is a great pleasure to be here, Mr. Chairman.

The CHAIRMAN. The next witness whom we are very glad to have appear before us to give us the benefit of his views, is Dr. James A. Van Allen, professor of physics, State University of Iowa.

Dr. Van Allen, we are very glad to have you appear before us. You may proceed.

STATEMENT OF DR. JAMES A. VAN ALLEN,[23] PROFESSOR OF PHYSICS, STATE UNIVERSITY OF IOWA, IOWA CITY, IOWA

Dr. VAN ALLEN. I have made a brief prepared statement, Mr. Chairman, which I believe has been distributed to the members of the committee.

By way of identification, I should say what my general interest and background in this area is so that you may know from what experience my point of view stems. I have been working in the field of high-altitude research with rockets for about 12 years now since the beginning of the subject in the United States.

Recently I have been specially concerned with the scientific measurements which can be made by satellites and it is in my laboratory that much of the apparatus was built which is presently being carried around the earth by Explorers I and III.

I may say I have a fairly sharp difference of opinion with General Loper on the primary purposes of outer space research.

I feel that the purposes are in the following order: First, there is the basic investigation of geophysical and astrophysical phenomena. We must realize that there is a vast area of ignorance about what is going on around the earth from the standpoint of physical phenomena. It is in this field that we have been working for 12 years using vertically fired rockets and it is in this field that the emphasis of satellite work has been up to the present time.

In the second place, it is clear already that there will be substantial civilian applications of outer space vehicles I may mention 1 or 2 of those as primary examples.

One example is in the study of weather on a worldwide scale and in the reliable prediction of weather. The civilian applications of such predictions are vastly more important than the military ones

As a second example, there is the clear prospect for a great improvement in high speed radio communications on a worldwide scale by the use of satellites. I believe that these developments likewise will be of much greater benefit to the citizenry at large than to military operations alone.

In the third place there is the purpose of space development which I have called the field of human adventure and exploration. I think this is the field which Dr. von Braun has emphasized before this committee.

I have no special comments to make on that I think it is not a hard-boiled, immediate need of the country, but it is certainly a natural field for human activity and will very likely be an important one in the long run.

Fourth, I would list the development of military applications as a field of importance, but, in my opinion, one of less importance than the civilian possibilities for the benefit of fundamental understanding, for the benefit of agriculture, and for the benefit of the citizenry at large.

I think that in many discussions of outer space, the cart is very much before the horse. Those of us actually working in this field clearly recognize the great ignorance which exists with respect to what is going on outside the earth. In my opinion this must be our first and most important concern for the next few years, the obtaining of basic knowledge about what is happening. The applications must follow knowledge—because if one does not know what is going on, he certainly does not know what to do with it.

I have the strong feeling that the Department of Agriculture, for example, might have more cognizance and basic interest in the research in outer space than Defense, actually.

The principal part of our space program in the United States has been during the past 12 years, beginning in 1946, the use of vertically fired rockets for exploration up to about 200 miles. This field will naturally and necessarily continue to be a rather large area in outer space research. I think one must not jump over all the "here and now" techniques used in physical science to the dreams of distant space voyages such as whistling around the planet Venus on an ion beam. We have a great deal of "here and now" technology in vertically fired rockets which is by no means fully exploited. Satellites are, however, greatly superior vehicles for doing certain types of scientific measurements in the vicinity of the earth. I have a very keen appreciation of this point, personally, because I have been working for about 12 years in measuring the radiation intensity at high altitudes above the earth by means of rockets. But in the data already received from Explorers I and III we have enough measurements to supplant, I should estimate, several hundred years of work by our previous techniques. So there is, in many areas, a very great increase in effectiveness which a satellite makes possible in many scientific areas.

I should like to enter the following summary statement, which is in my written statement, that I feel our national space program in the immediate future should emphasize the thoroughgoing investigation of physical conditions pertaining to the earth. This is my feeling

as to its most essential and hard-boiled immediate future. It is reasonable to expect that there will be quite substantial applications.

I mentioned two of them; the study of the motion of air and cloud cover and of hurricanes above the earth, and the general field of weather prediction which I think must be and should be regarded as primarily a matter of civilian welfare; and, second is the one having to do with the conduct of high speed radio communications on a worldwide basis. Here again, although there are undeniable military possibilities. I think that the primary concern is a civilian one.

In the field of human exploration and adventure, there are many enthusiasts for flying men in space vehicles. It has been a fascinating field of human speculation. I feel somehow that we must do so in due time. Before we do it, however, there is a great deal of preparation required. There need to be flights of simple biological specimens. There need to be progressively, flights of animals of progressively greater complexity, approaching that of man. I feel that before we can prudently place a man in space, there must be a very substantial period of preparation.

On the subject of military applications, I think many of these things which I classify as primarily civilian applications are of military importance as well.

I think one can break down the subject something like this; there is certainly a very strong and immediate military need for being able to hurl, a 1-ton object 5,000 miles, and I think no one can dispute the fact that doing so is clearly a military undertaking. But when one speaks of placing scientific apparatus in an orbit about the moon, I feel that this is much more clearly a purely scientific undertaking at this stage, and that is military importance is very difficult, if not impossible, to demonstrate to a critical person.

Now, I understand I am to speak specifically with respect to the pending bill, H. R. 11964 (identical to H. R. 11881). As a general statement, I strongly support the language and intent of this bill.

I may say that there was a bill introduced by Representative Coad, of Iowa, H. R. 9966, early in January. I personally prefer Mr. Coad's bill in a number of detailed respects although the basic intent is similar to that of H. R. 11964.

Now in accordance with the spirit of 11964, I would like to emphasize the fact that I feel that civilian management of a space program is a very vital matter, and, as a matter of national policy, I strongly urge that there be such civilian management.

The essential issue, of course, is who has primary cognizance over space among all Government agencies. I feel the language of this bill should be strengthened substantially to make it clear that the NASA will have primary and dominant cognizance of space matters among all Government agencies, and that only in case it is clearly demonstrated that an endeavor has a direct importance to our military preparedness, a direct importance, a direct and short-term importance, such as intercontinental ballistic missiles, should the primary cognizance reside in the Defense Department. The Defense Department has vast facilities which will be quite useful in any space endeavor—use of ships, proving grounds, and so forth. At the same time, the Military Establishment will profit by space research. But I feel that the primary cognizance should rest with the proposed civilian agency, the NASA. But no matter how well written the

legislation we have available as enabling legislation for NASA, the real crux of the matter is how it is funded, because without that its creation is a hollow gesture.

As a matter of estimation of what is required, I would submit the following remarks:

Our present IGY national satellite program is reliably estimated to be costing us about $150 million. As you all know, this is a very small start in the undertaking of exploring and utilizing outer space. So I think it is clear that something of the order of $500 million a year will be required for a vigorous national space program.

There is also the issue of how to go about actuating the NASA. I have a few remarks on that:

I think it has already been included in the bill that the proposed Space Agency would immediately encompass all the present activities, facilities, and personnel of the NACA.

In addition to that, it appears to me to be vital that all activities of other Government agencies, which are principally concerned with space endeavors, also be transferred to the administration and supervision of the NASA as rapidly as this can be done. There are many agencies with which I am personally familiar which can be transfered readily to the new NASA.

The CHAIRMAN. You notice there is a provision in the bill authorizing, under certain conditions and within a period of 3 years, the transfer of other agencies and functions to the new Agency?

Dr. VAN ALLEN. Yes, sir. I favor that, although I think the time scale implied is rather longer than I should like to see. Three years is a long time in this game.

The CHAIRMAN. They do not have to wait 3 years.

Dr. VAN ALLEN. That is right.

The CHAIRMAN. I notice the Coad bill prefers the commission form of agency rather than director.

Do you favor that?

Dr. VAN ALLEN. Yes, sir; although I think that General Loper is much better able to speak from personal experience. However, I have had some experience with the Atomic Energy Commission's operations, and I think that, as in that field, the field of space research is a very diverse one. There are many aspects: Astrophysics, astronomy, geophysics, biology, medicine; there is propulsion, guidance, communication, telemetry. It is quite a vast technical field.

I feel that a greater diversity of policymaking talent is required than would likely be possessed by any single person as a director. I realize that there is inevitably a certain amount of pulling and hauling that will go on among five different persons, but I think that is just the pulling and hauling one needs to come up with a balanced national program in the space field.

So I do favor the commission idea as represented in Mr. Coad's bill.

That is a summary, Mr. Chairman, of my feelings about the principal points.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. Dr. Van Allen, I am glad to hear you say that you strongly support the language and the intent of the present bill before the committee.

As you know, the President and others have thought that now is the time to set up a new agency and it was important that a National

Aeronautics and Space Agency be created and brought into use at this time.

The members of this committee, Dr. Van Allen, have certain ideas on the type of agency we should have. There are other Members of the House, as you probably know, who may not agree that a new agency is required at this time.

The question will arise on the floor of the House at the time this bill is presented as to why we need a new agency. We have the National Science Foundation, we have the National Advisory Commission for Aeronautics, and we have the Atomic Energy Commission, and so on down the line. They will all be enumerated.

The bill before us, H. R 11881, which was introduced by our chairman, Mr. McCormack, sets forth, under the declaration of policy, some of the reasons why we need a space agency at the present time.

I read a statement this past week, Dr. Van Allen, that I would like to read into the record, and I want to see if you agree with it.

The statement is as follows:

> The vital point is not so much that the Soviet satellite preceded that of the United States, heretofore credited as the leader of world technology. It is that the United States for the first time finds a challenging competitor in the most advanced scientific fields.
>
> What most Americans did not know is that we are in a desperate race for control of man's mind, an intellectual race which is brought to light by the Russian sputnik and the complacency of our assumed technological lead.
>
> We have confused our high standards of living and material prosperity with intellectual stature. It is an extravagant and dangerous mistake.
>
> The race for intellectual preeminence has as its objective the creation of a new instrument of national policy to supplement the traditional instruments of military power and of national wealth.
>
> The instruments of foreign policy before the satellites were launched were physical strength, productive capacity, and national wealth.

Dr. Van Allen, do you agree in substance that that statement is correct?

Dr VAN ALLEN. I have a very deep sympathy with those views. In fact, as one whose primary interest is in teaching, I see this every day.

I think it is quite easy to visualize, if we don't get cracking on this field, that my young son, for example, will want to go to Russia to study physics. By the time that he is of college age, it may well be that this is the best place to do so. I think that we are strongly in danger of loosing intellectual leadership. Before and even after World War I, everyone who wished to study advanced science and medicine went to Europe. If one wished to study science, he went to Germany. If one wished to study medicine, he went to Vienna. It could easily happen that 10 years from now a bright young man in the United States would be well advised to go to Moscow to study physics. I would bitterly regret that.

I think we will become a second-rate nation if we do not support our best talent in basic research and intellectual endeavor.

Mr. NATCHER. Assuming that you were a Member of the House and had to present this bill to the membership for action, and the question were asked you as to why we need a new agency, at the present time, entitled "The National Aeronautics and Space Agency," what would your answer be?

Why do we have to have this particular type of agency at this time when we have these other organizations which might, if enlarged somewhat, serve the same purpose?

Why this particular agency? Why space, at the present time, and why should we pass legislation setting up the National Aeronautics and Space Agency, which, as you know, will take over the Advisory Aeronautical Agency?

What would your answer be, Dr. Van Allen?

Dr. VAN ALLEN. Well, sir, I don't think one can name any existing civilian agency of the Government which is constituted to handle a large undertaking of this character. The NACA has a yearly budget of $100 million and it has considered itself as basically a service agency to the aircraft industry and to the Defense Department. I feel that an agency to undertake space research must be a major agency of the Government. It must be a free standing one which has dominant cognizance over certain areas. There is no such agency within the Government establishment at the present time

Mr. NATCHER. Dr Van Allen, this question might be asked. Why not let the NACA proceed? They have $500 million worth of property they are using. They have 7,600 employees, some 4,000 of which are scientists or people qualified along that line.

What would your answer be there? Is this space agency necessary when we have NACA?

Dr. VAN ALLEN. Sir, I have a certain familarity with NACA and I am presently serving on one of their committees. I have served on previous committees of the NACA I think that it is an organization of a high level of competence but its spirit is primarily one of being a service agency to the aeronautical industry and the Defense Department in aeronautics It is conceivable that they could do it, but two things would have to happen. In the first place they would need a greatly expanded charter—one, in fact which is equivalent to the one in the proposed legislation for the NASA.

Next, they need a greatly expanded budget.

The CHAIRMAN. Do they need new minds, too?

Dr. VAN ALLEN. Yes, sir; I think they do in this field. They have relatively little work going on which in my opinion is directly pertinent to the space undertaking.

Mr. NATCHER. Dr. Van Allen, I want to thank you for the fine statement you have made to this committee. I personally believe that now is the time for the establishment of a National Aeronautics and Space Agency, and I think this legislation is imperative. But in order to justify our position and to obtain your reasoning, is why I went into this particular phase of it

Thank you, Mr. Chairman.

The CHAIRMAN. As between the commission form of agency and the director, you would favor one or the other?

Dr. VAN ALLEN. Yes, sir; I favor the commission.

The CHAIRMAN. In any event you favor strongly the creation of a new space agency?

Dr. VAN ALLEN Yes, sir, by all means

The CHAIRMAN Mr. McDonough

Mr. McDONOUGH. Dr. Van Allen, I appreciate your fine statement. It is pertinent and to the point. I appreciate your emphasis upon the civilian development of the use of space with, of course, the attendant results and benefits it will be to the military defense of the Nation

In the title of this Agency, the National Aeronautics and Space Agency, the relationship of aeronautics and astronautics is very close. In your opinion, is this true?

Dr. VAN ALLEN. Well, they have something in common, but I think they are quite different, actually. Aeronautics as, we presently understand it, is quite a long cut below astronautics in technical difficulty.

Mr. McDONOUGH. Would the title of the Agency be more descriptive and better understood if it were a national aero-astronautics agency instead of just space?

Dr. VAN ALLEN. I would personally favor National Commission for Astronautics and Space Research—something of that character. I think it is a little unfortunate to perpetuate the use of the word aeronautics, because that means manned aircraft from Chicago to Washington, and to New York, and so forth.

It should be a cleaner break with the past.

Mr. McDONOUGH. You believe in basic research in astronautics that we will discover new and better means for aeronautical travel?

Dr. VAN ALLEN. Yes, sir, I think that is a long-range possibility—for example, flying 50 people in a rocket from New York to London. I think that it will be a quite long time before we will be doing that reliably. I think, that for at least the next decade, we will not have any appreciable influence on human transportation in this field no matter how vigorously we undertake it.

Mr. McDONOUGH. Do I understand you to say that the title, "National Aero-Astronautics Agency" would be no more descriptive than just the Aeronautics and Space Agency?

Dr. VAN ALLEN. Yes, sir, I think it would.

Mr. McDONOUGH. Space is a vast area and astronautics is the means of communication and travel in space; is it not?

Dr. VAN ALLEN. Yes, sir.

The CHAIRMAN. The new agency will carry on its former work?

Dr. VAN ALLEN. Yes, sir. I know that General Doolittle has stated that they intend to shift the emphasis within the existing NACA establishment rather strongly toward rocket propulsion and guidance and space undertakings.

Mr. McDONOUGH. I think the committee ought to consider the title of the agency as Aero-Astronautics rather than Aeronautics and Space.

I think we have a competent witness here who agrees on the name.

Dr. VAN ALLEN. It is a bit of a mouthful, sir. I prefer a simpler name.

The CHAIRMAN. What counts is the provision of the bill, though?

Dr. VAN ALLEN. Yes, sir.

The CHAIRMAN. We can consider that in executive session.

Mr. McDONOUGH. Do you think that we have in the United States at the present time the potential manpower in scientific minds to carry on from here, or do we have to augment that by a crash program on interesting students in scientific study?

Dr. VAN ALLEN. That is very close to my daily business, teaching science. I think a crash program is very difficult to manage. It takes us 25 years to produce a Ph. D , starting from scratch. It takes us about 8 years, even after a candidate leaves high school.

So I do not think that a crash program can have a very immediate impact on our technological capabilities in the United States. Now,

I am very strongly in favor of stiffening up the educational system all the way down the line, and I think there is quite a significant tendency in that direction now. I include not only science. I think we can well overdo scientific and technical education. I am as interested in having Latin and grammar taught in high school, as I am in having solid geometry and physics. I think we need a stiffening up of the general character of our education.

Technicians can be turned out in a crash program but persons of broad and deep understanding cannot. I feel that it will take a minimum of 10 years to make a substantial change in fundamental education in the United States.

Mr. McDonough. With the scientific manpower we have in the United States at the present time, if it is marshaled, coordinated, and emphasized on space science—do you think we are in pretty good shape right now as compared to Russia?

Dr. Van Allen. Yes, sir, I think we have a vast scientific and technical capability in the United States.

My feeling is that the main element which has been missing is sensible management on a national level for national objectives. I think that one of the most important reasons for the creation of the NASA is to provide effective management and direction of national efforts in the space field.

The Chairman. Dr. Hovde agrees with you on the question of management.

Dr. Van Allen. Yes, sir. We have a great many competent people in the United States devising ways to raise tops of convertible cars when it starts raining on the seats, and so forth. This is all very nice, but I think it is vastly less essential, nationally, than doing some of the things which we have discussed this morning.

I think that the necessary talent exists but that it is not being employed for the national welfare.

Mr. Chairman, may I remark that one special feature of civilian management in the United States is that it provides immediate possibilities for international cooperation. For example, at the present time we have IGY satellite observing stations distributed over the world in at least 20 different countries. Both practically and diplomatically, this is a very fine undertaking, but it is not at all clear how such arrangements can be managed if space is a military undertaking.

I think it is rather difficult to imagine, let us say, the United States Air Force and the Soviet Air Force collaborating on any undertaking, but I can easily imagine our national space establishment collaborating with the corresponding civilian establishment in Russia for mutual benefit, and with the other countries involved in the IGY.

Mr. McDonough. Do you think the IGY effort should be continued instead of terminated this next year?

Dr. Van Allen. Yes, sir, I certainly do.

Mr. McDonough. Are these minitrack stations established for the IGY to be terminated when the year is over?

Dr. Van Allen. That is the specific arrangement. Most of us hope that it will not come to pass, that they will be dismantled at the end of the IGY.

We have stations at the present time in Nigeria, Singapore, British West Indies, Iran, South Africa, Cuba, Hawaii, the Philippines, Ecuador, Peru, Chile, Australia, and so forth.

Mr. McDONOUGH. When the IGY year terminates and we shoot satellites up, we will not have minitrack stations tracking?

Mr. VAN ALLEN. If we do not make arrangements for continuing the operation of observing stations, we will shoot them, and we will not know where they go.

Mr. McDONOUGH. Your plans right now are to continue minitrack stations?

Dr. VAN ALLEN. Yes, sir; also a number of stations called microlock stations, established by the Jet Propulsion Laboratory. There are also a large number of optical observing stations established under the supervision of the Smithsonian Institution. These are all international networks at the present time.

Mr. McDONOUGH. You think this Agency should be authorized to take over the operation of those stations as one of its fundamental purposes?

Dr. VAN ALLEN. Yes, sir, and to make international arrangements for such purposes.

Mr. McDONOUGH. And that this Agency should be the parent body for basic research on astronautics and space exploration?

Dr. VAN ALLEN Yes, sir

Mr. McDONOUGH. Up to what point should it cease to be an operating agency, or should it get into the operating end? Should it build and operate test material? Should it produce in quantity any space ships or satellites?

Dr. VAN ALLEN. My feeling would be, sir, that it should be an operating agency in the sense that it would have proving grounds under its own administration. It should have tracking stations as required—an international network of tracking stations. It should have optical observing stations and should be a self-sufficient agency insofar as conducting the operations are concerned It might well, for example, operate a permanent system of meteorological satellites.

Mr. McDONOUGH. Do you think the Weather Bureau as now constituted should become part of a subsidiary organization to this Agency?

Dr. VAN ALLEN. It should certainly be closely associated with it. I should not like to pass on the matter as to whether it should be absorbed into it or not, but it certainly should be closely associated and I am sure it will be.

Mr. McDONOUGH. That is all, Mr. Chairman.

Mr. NATCHER (presiding). Mr. Fulton.

Mr. FULTON. As the matter now stands, the Vanguard program has been an International Geophysical Year program, so there is no authorization to continue the Vanguard program by law beyond December 31, 1958; is that not right?

Dr VAN ALLEN. That is correct, to the best of my knowledge.

Mr. FULTON. So that in order to continue the Vanguard-Explorer programs, as well as programs of civilian research and exploration into outer space, separate from military weaponry programs, we in the United States need specific statutory authorization; do we not?

Dr. VAN ALLEN. Yes, sir; that is correct.

Mr. FULTON. When you spoke of whistling around the moon in an ion-propelled vehicle, you were not discounting the ion-engine method of propulsion; were you?

Dr. VAN ALLEN. I tend to, as an immediate prospect. But it is a very interesting principle and it will likely have application eventually.

Mr. FULTON. But on the program of research that is now going ahead on ion propulsion you would not, because of that statement, imply that this committee should recommend the cessation of a program of study?

Dr. VAN ALLEN. No; it has prospect of important application in the long run. But it should be recognized that propulsion by means of chemical fuels is enormously more important for the immediate future.

Mr. FULTON. If it will take 10 years to get an ion-propelled vehicle in outer space we should be in the basic study of it now?

Dr. VAN ALLEN. Yes, sir.

Mr. FULTON. Likewise on light propulsion you would recommend continuation of programs of research?

Dr. VAN ALLEN. Yes, sir; on a modest scale

Mr. FULTON. And on sail effect, taking advantage of solar energy you would likewise recommend research?

Dr. VAN ALLEN. Yes, sir; these are sound principles which will have their effects felt in the long run.

Mr. FULTON. Do you recommend the immediate construction of a million-pound thrust engine. Is that the area of magnitude you would emphasize?

Dr. VAN ALLEN. That is an important device and I would say it is a much more immediate need and a much more immediate prospect than a practical engine operating on any other principle you have mentioned.

Mr. FULTON. How long do you think it would take to develop such a vehicle and what would the cost be?

Dr. VAN ALLEN. I understand from people who have been working on this that 3 or 4 years is the general scale likely required for a single unit. Of course one can bundle together four 250,000-pound engines

Mr. FULTON. We are talking of a single unit engine and not 3 ¼-of-a-million engines.

Dr. VAN ALLEN. A single 1-million-pound thrust engine in several years at a minimum. Since no one has done it in this country, the difficulty is not clearly known, of course.

Mr. FULTON. What do you think the magnitude of cost will be?

Dr. VAN ALLEN. I think it runs approximately a billion dollars as the estimate of what is required for full development and prove-in.

Mr. FULTON. At the rate of $500,000 annually, which the Government has started to give for study of the development of the million-pound-thrust engine, it would then require how many years? It would take 2,000 years?

Dr. VAN ALLEN. Yes, sir.

Mr. FULTON. Would you then recommend that the program be stepped up immediately by appropriation of a substantial amount of money for the development of the million-pound-thrust engine for the travel in outer space?

Dr. VAN ALLEN. Well, sir I would think we need a good many things more than we need that. If we really wish to carry a substantial payload into outer space and specifically to the moon, we do need that. I prefer more emphasis on more modest vehicles for

the next 5 years; namely, vertically fired rockets, satellites of the earth and instrumented flights to the moon.

Mr. FULTON. But the President having ordered a lunar shot, then the question comes up, how to do it, and, of course, the million-pound-thrust engine is the vehicle which is best suited.

Would you then not recommend such a program at the present time for the construction of the million-pound-thrust engine rather than put it off?

Dr. VAN ALLEN. I favor getting on with this job; yes, sir. But I do not think such a development should dominate our space effort in the next several years.

Mr. FULTON. You stated in your previous testimony that to project a 1-ton object 5,000 miles through space in your opinion was a military proposal or military jurisdiction.

Why is it not equally a civilian proposal when we might be using that form of transportation for people or for freight or for communication?

Dr. VAN ALLEN. I think the military need is much greater in that particular example. Certainly the Military Establishment must be able to deliver an H-bomb or A-bomb 5,000 miles. Certainly no one disagrees with that as a pressing military requirement.

Mr. FULTON. You said you had experience on obtaining by telemetering or monitoring the results of the signals from the Vanguard and the Explorer programs. Likewise you have stated the amount of information already received from our United States earth satellites has been the equivalent of several hundred years of effort by previously accepted standards?

Dr. VAN ALLEN. That is correct.

Mr. FULTON. Would you kindly tell us in comparison how much information you have received from Sputniks I and II and how many years it would have taken us in the free world to have obtained that knowledge?

First, are you getting the information, and second, how much are you getting?

Dr. VAN ALLEN. We have received the radio signals from both Sputnik I and Sputnik II at numerous stations in the United States. But we have not received from the Soviets the detailed code which is essential to understanding what information is being transmitted.

Mr. FULTON. Under the Geophysical Year arrangements and agreements that code was to be given to you; was it not?

Dr. VAN ALLEN. That is correct, although it was somewhat vague as to how soon they must do that.

I was a member of the United States delegation to Barcelona in 1956 in which this matter was discussed and agreed upon. They are not obligated to provide either the code or the information resulting from interpretation of the measurements until 1 year after the observations have been taken.

That year, of course, has not elapsed. I should say we might well credit them with good faith, in the absence of any evidence to the contrary so far.

Mr. FULTON You do not feel that the Russians have broken any agreements by not giving us the results of their Sputniks I and II firings, nor by giving us a code? That is a very unusual statement.

Dr. VAN ALLEN. I say they have not broken any explicit agreement. I think they have not acted as rapidly as we might expect a friend to

act, but they are within their agreement at the present time. I might say we have not sent, yet, to the Soviets any information of a substantially revealing character of our findings with our Explorers.

Mr. FULTON. Should we?

Dr. VAN ALLEN. We should, and as you perhaps know, on Thursday of this week a number of us are giving public papers on what we have learned so far These papers are being assembled by the National IGY staff and will be transmitted to Russia within the next 2 weeks.

Mr. MCDONOUGH. Are we obligated by treaty?

Dr. VAN ALLEN. It is not a treaty in the strict sense. It is more in the nature of a gentleman's agreement within the IGY structure.

Mr. FULTON. Actually there is no Government agreement at all to give it to them, it is only within the IGY agencies?

Dr. VAN ALLEN. That is right.

Mr. FULTON. It is not a treaty approved by the Senate, nor a binding executive agreement?

Dr. VAN ALLEN. That is correct. It is essentially a matter of informal understanding among scientists working in the two areas and is a matter of record in the IGY proceedings.

Mr. FULTON. In the field of which you have knowledge, are we going to make public a substantial or full amount of the findings we have made of general basic knowledge so that the scientists of the world can have access to them?

Dr. VAN ALLEN. Yes, sir, we are. I will personally present a paper on our results with Explorers I and III. There are three other papers to be given on Thursday at the National Academy. Copies of the papers will be bundled up and sent to all the IGY world data centers within the next week

Mr. FULTON. So our United States scientists have decided on the policy of full disclousre for the gain of scientific knowledge in the whole world?

Dr. VAN ALLEN. Yes, sir. The President has made such a statement of policy and we are complying with it fully.

Mr. FULTON. Let me finish with this. The first is on the commission form as against the director form of organization of the Space Agency.

Personally I prefer the name "Space Agency," United States Space Agency for Research and Exploration, leaving out the word astronautics and aeronautics—one woman has talked to me and suggested that astronautics meant the reading of sailor's pamphlets.

On the setup as it is now we have the 17-man advisory committee, we have the Director, Dr. Dryden, we also have the Executive Secretary, the Associate Director.

In addition to that, we have the Chairman of the Advisory Committee, General Doolittle, who has access to the President when he wants to see the President about the operations of NACA.

Therefore, at the present time we actually have a 4-man operating agency although it is called an advisory committee, with a 7-man executive committee who live in or near Washington and give their full or almost full time to the operations of NACA; do we not?

Dr. VAN ALLEN. Yes, sir.

Mr. FULTON. In effect, then, we have a partial commission setup of the operations at the top level of the National Advisory Committee for Aeronautics right now; do we not?

Dr. VAN ALLEN. It is not clear to me that this is equivalent to a commission.

Mr. FULTON. But partially a commission form, really, at the present time, would you not agree?

Dr VAN ALLEN. Yes, sir, I think it has some resemblance to being a commission but I prefer the AEC pattern wherein the five commissioners are on the job every day as a regular job, and make their full business the determination of policy of the commission.

Mr FULTON As a partial step in that direction I submitted last year a resolution for a joint congressional committee modeled on the Joint Atomic Energy Committee of Congress to start procedures going in that area

May we finish with this

We have the jet air streams above the world that may go 150 to 200 miles per hour, caused by the centrifugal force of the world's turning. They are largely responsible for our tornadoes, cyclones, monsoons and our unusual weather conditions. I saw the atomic shot in Nevada and saw this tremendous cloud of atomic and nuclear material going up into those jet streams. I have been concerned about the changes of weather and the moving of tornado winds that just 10 days ago knocked down some big trees on my farm where we never had such before.

They have moved west from the eastern seaboard, and now are hitting Pittsburgh, Pa

The question is, when you put up these nuclear shots, and this is your field, tremendous clouds go up into those jet streams. First, they physically replace a large area occupied by the jet streams in a straight flow and, second, they do have an effect because they mix in those jet streams a tremendous amount of material that is radioactive and molecularly unstable. We do not know what occurs when the sun hits it—some of those molecules may ionize—because we never have had any experience; is that not correct?

Dr. VAN ALLEN. That is correct.

Mr. FULTON. In your view, is it possible those explosions are having something to do with our change of weather, with Pittsburgh getting big storms where they always went up the east coast?

Dr. VAN ALLEN. No, sir; I would not agree with that.

Mr. FULTON. Why not? I would like to hear that.

Dr. VAN ALLEN. I do not consider myself an expert in this field. But I am familiar with the work of the Weather Bureau and of the President's Commission concerning the possibility of the control of weather.

Mr. FULTON. Why, when we put a tremendous mass up there of radioactive materials that expand tremendously, does it not cause the jet streams of these tremendously potent winds to divert or otherwise mix them up?

Dr VAN ALLEN. It is a quantitative question. The forces of nature are vast. The forces of the atomic bomb are vast. But nature is much more vast than atomic bombs. I think that is the essence of the situation. You ask me do I know. I will say I do not know, but I think the matter is under very competent study, and the burden of conclusion at the present time is that it is not likely that a substantial effect results

Mr. FULTON. At the point of impact of a nuclear explosion, as it extends to these jet streams, is there not a diversion of jet current of winds?

Dr. VAN ALLEN. There must be some local perturbation, but whether that is substantial, I do not know. I think the weight of evidence at the present time is that it is not.

Mr. FULTON. There is a turbulence caused?

Dr. VAN ALLEN. Yes.

Mr. FULTON. Thank you.

That is all, Mr. Chairman.

Mr. NATCHER. Mr. Keating.

Mr. KEATING. Dr. Van Allen, you indicated some of the civilian uses to which outer space might be put, and one was weather.

Dr. VAN ALLEN. Yes.

Mr. KEATING. And the greater facility which we would have in predicting weather. Do you envision the possibilities of controlling the weather, also?

Dr. VAN ALLEN. I would answer about the same way. I certainly do not know. I think it is clear that we must study weather on a much more comprehensive scale in order to approach that possibility. I think it is quite competently agreed now that it will be possible to greatly improve the reliability of weather forecasts by means of satellites. And I think it is agreed that further study of the weather will be the best way, and probably the only way, in which any competent assessment of the possibilities of weather control can be made.

Mr. KEATING. In other words, you will have a much more comprehensive picture of weather, how it is created and changed, from outer space than you do from the atmosphere?

Mr. VAN ALLEN. Yes, sir. With a satellite we can, of course, go around the world every 2 hours, and we can cover the whole surface of the earth in 1 day. We have the prospect for comprehensive and detailed observation to an extent inconceivable by any other means. The spirit of our work at the present time during the IGY is to study the weather and learn more about it, see how it works. I think it is almost certain that we can achieve a great improvement in the reliability of short-term forecasts and, also, long-range forecasts, such as seasonal forecasts. We may be able to reliably predict that this summer will be a dry summer in the Middle West, for example. Whether or not we can exert any control is not at all clear, but I think it is clear that this is the best way to attack that undertaking

Mr. KEATING. It could have far-reaching effects on our relations with other countries where weather is practically their life?

Dr. VAN ALLEN. Yes, and I think we should certainly be aware of the importance of these matters on our agriculture in the United States. It could have a vital influence on agricultural decisions to know in advance what sort of season there is likely to be in an area.

Mr. KEATING. Spoken like a true Iowan.

Dr. VAN ALLEN. I feel very strongly on this.

Mr. FULTON. How do you explain the great increase of tornadoes in the Midwest since the nuclear explosions?

Dr. VAN ALLEN. I do not think that there is any connection between tornadoes and nuclear explosions. Again, I do not consider myself an expert on this matter.

Mr. KEATING. You spoke, also, of a worldwide TV system which could be brought about by further exploration of outer space.

Dr. VAN ALLEN. Yes.

Mr. KEATING. That is as near to a scientific certainty as most anything can be; is it not?

Dr. VAN ALLEN. Yes, sir.

Mr. KEATING. Are there other civilian opportunities which you envision here, other than those two?

Dr. VAN ALLEN. There are others of a more speculative nature. I think those are the two best grounded possibilities, but there are others of a more speculative nature.

For example, we are avidly studying the nature of radio transmission, long-range radio transmission, and there may well be substantial advantages in ordinary radio transmission by virtue of what we learn in the ionic layers of the atmosphere.

Mr. KEATING. Does the solar radiation work you have been doing have possibilities?

Dr. VAN ALLEN. Efforts are being made to find out whether extraordinary outbursts on the sun influence the upper atmosphere and whether, in turn, they have an effect on the communications.

Mr. KEATING. Are you going to bring that radiation down here to heat our homes?

Dr. VAN ALLEN. I do not think we will be able to do that. The anticipated benefits are indirect ones, resulting from a better understanding of the physical phenomena involved. Then, if we have a satellite continuously observing solar radiations, we would know what to expect.

Mr. KEATING. What would the practical effect be on everyday life?

Dr. VAN ALLEN. I think it may well result in better radio communication around the world, for example.

Mr. KEATING. Under the IGY program, is it not a fact that the arrangement was for each country to give its information 8 months after it had started its experiment?

Dr. VAN ALLEN. It was 8 months in the first draft. It was later revised to 1 year.

Mr. KEATING. So the Russians really do not owe us this, nor do we owe the Russians information until 1 year after the experiment; is that correct?

Dr. VAN ALLEN. That is correct

Mr. KEATING. If either country furnished that information within that 1 year they would be complying with the agreement the scientists reached?

Dr. VAN ALLEN. That is correct, sir. I think the spirit of it is that it should be as prompt as possible, but at the outside 1 year. It is evidence of good spirit and good faith to do it promptly, but you are not in violation of the agreement until 1 year has elapsed.

Mr. KEATING. You scientists here plan to do it just as soon as you give your papers?

Dr. VAN ALLEN. Yes, sir.

Mr. KEATING. Will the papers tell the whole story of what we have found out?

Dr. VAN ALLEN. They will contain the whole story up to the time we have prepared them. We have by no means reduced the entire body of data from Explorer III, for example. I have a busy place in Iowa City where we are working day and night doing this. Our paper

which will be given on Thursday of this week contains the results from the first 2 weeks of the flight of Explorer III and for most of the flight of Explorer I. By the end of the summer we will know a good deal more because it is a lot of work just seeing what the results mean.

Mr. KEATING. It is our plan to furnish that information to scientists throughout the world just as soon as we have it available?

Dr. VAN ALLEN. Yes, sir.

Next week a copy of this report will be sent to every national committee participating in the IGY—some 68 countries.

Mr. KEATING. There has been talk here of the $500,000 which is the allotment this year for the study of the million-pound thrust engine. Statements have been made that it would take 200, 300, 1,000, or 2,000 years at that rate to develop it.

Now, I want to bring this out. We have many programs that we have to divide our resources among Is that not right?

Dr. VAN ALLEN. Yes.

Mr. KEATING. You, yourself, do not place first emphasis or first priority on the million-pound thrust engine?

Dr. VAN ALLEN. That is correct; I do not.

Mr. KEATING. It is a highly desirable development and if it is given the priority, if its priority is shoved up, obviously it will take a vastly larger amount of researchers to develop it.

Dr. VAN ALLEN. Yes, sir.

Mr. KEATING. Have you heard anybody seriously contending that this should be a 100- or a 200-year project, or anything of that kind?

Dr. VAN ALLEN. No; I think that is such a long scale we need not bother at all.

Mr. KEATING. In other words, there are many things in the research stage where modest amounts are now being spent. But if they reach a certain point, very much greater sums will have to be spent?

Dr. VAN ALLEN. Yes, sir; I think personally the million-pound engine is a very desirable long-range development is we really wish to send up very large payloads and actually land a party of men, say, on the moon.

Mr. KEATING. But you do not need that million pound thrust engine for what the President has directed, a lunar probe?

Dr. VAN ALLEN. That is correct. We are going to do that within this calendar year with what we have.

I would much rather see heavy emphasis on doing geophysics and astrophysics within the atmosphere of the earth as the primary business in the next several years.

Mr. KEATING. You raised an extraordinary point about our scientists in this country. Nearly everyone who has appeared here has shared your views that we have topnotch scientists in this country. One great problem is to put them to work on the most important projects within and without the Government. It is a good deal like deciding where the most important place to spend money is.

How can we get scientists to shift from working on better ways of putting a convertible top down over to working on a space ship? How can we interest them in that?

Dr. VAN ALLEN. Of course, we cannot in this country just go out and order them to do it. I think we must do it by two means.

Mr. KEATING. You would not be for that?

Dr. VAN ALLEN. No, sir.

Mr. KEATING. You would not be for ordering one to go there and this one here?

Dr. VAN ALLEN. No, sir; I think we ought to make it attractive enough. The attractions are the technical and professional challenges. The financial challenge is present but is, in my opinion, secondary. I think the main challenge is in the spirit and possibilities of the undertaking

I think if we have an NASA in operation we will have no difficulty in getting competent people to do the work.

Mr. KEATING. You feel that the creation of this Agency would be a very important step forward in interesting scientists in this field.

Dr. VAN ALLEN. I think it is a vital step. I think it signifies the national level of interest in this subject, the fact that it is a matter of public policy that we are going to do this vigorously. I think we will have no trouble manning the show with thoroughly competent people.

Mr. KEATING. We not only must man this show, speaking of the NASA or a comparable agency, but we must interest scientists in private enterprises and industrial concerns to take an interest in this field.

Dr. VAN ALLEN. Yes.

Mr. KEATING. You do not have in mind that they will all be concentrated, of course, in the NASA?

Dr. VAN ALLEN. No, sir; I think the NASA should work in large part by contract.

Mr. KEATING. When you said it would take 25 years starting from scratch to develop these Ph. D 's, we do not start from scratch if we are on our toes, do we? You are talking from birth?

Dr. VAN ALLEN. That is correct. We start with entrance in college in my opinion.

Mr. KEATING. In 8 to 10 years, if we are alert, we ought to have the citizenry alerted to the needs of the moment so that we will have a definite improvement in this field?

Dr. VAN ALLEN. I think 8 to 10 years is about right; yes. I don't think that anyone should expect that next year there will be a big change in the output of Ph. D. physicists. That won't be so, no matter what you do.

Mr. NATCHER Mr. Feldman.

Mr. FELDMAN. In response to questions, you stated you served on several NACA boards and also have contact with AEC.

Dr. VAN ALLEN. I did not say close contact, but I have had some contact. I have had a contract with them and I have advised with them some

Mr. FELDMAN. You have had some contact?

Dr. VAN ALLEN. Yes, sir.

Mr. FELDMAN. Has the contact been as close as that you have had with the NACA?

Dr. VAN ALLEN. It is comparable; yes, sir.

Mr. FELDMAN. Is this the basis for your conclusion concerning the commission form versus an individual director?

Dr. VAN ALLEN. You mean the comparison of the way the two agencies work?

Mr. FELDMAN. Yes.

Dr. VAN ALLEN. No; it is not. I think both of them do work out more or less all right. The commission plan appeals to me because

of the diversity of the undertaking we are contemplating I have difficulty visualizing one man with the breadth of competence necessary to direct a national space program in all of its aspects.

Mr. FELDMAN. In your direct testimony you enumerated what those different functions were?

Dr. VAN ALLEN. Yes.

Mr. FELDMAN. I think in answer to a previous question there was talk about the present setup of NACA. The new proposal is section 6 under the functions of the Agency, beginning on page 5, but I am more particularly addressing myself to subsection 3 on page 7 which speaks of additional powers that I do not believe the present NACA has, and that is to:

> Acquire, construct, improve, repair, operate and maintain laboratories, research and testing sites and facilities, manned and unmanned aeronautical and space vehicles, quarters and related accommodations for employees.

and so forth.

It gives the new Agency the right to construct, if I can lift the word out of context, construct manned and unmanned space vehicles.

That seems to be something in addition to what the NACA can do at the moment.

Dr. VAN ALLEN. Well, I do not think so. I do not claim to be an expert on that point, but they are, for example, jointly building the X15 with the Air Force and the Navy. I think they are constructing it, in a loose way of speaking at any rate.

Mr. FELDMAN. If they can perform all these functions, then why do we need a new agency?

Dr. VAN ALLEN. I think we are talking about something of vastly enlarged scope. It is vastly enlarged, vastly larger in expanse, it is vastly larger in breadth. I think it contemplates much wider operation by contract than does NACA. NACA does very little by contract with private institutions.

Mr. FELDMAN. How would you distinguish between atomic energy in outer space and such matters as nuclear power for propulsion, having in mind the difference as between executive agencies and the military liaison of these agencies with atomic energy in outer space and congressional committees?

Dr. VAN ALLEN. You ask what should be the proper governmental agency——

Mr. FELDMAN. Let me see if I can reword the question this way:

NACA is at present engaged in the development of an engine for space propulsion?

Dr. VAN ALLEN. Yes.

Mr. FELDMAN. How would you coordinate that with this new Space Agency?

Dr. VAN ALLEN. I don't have any detailed proposal for that. Coordination is obviously necessary. The AEC is likely the one to continue its development in that area, but it certainly should be fitted to the needs of the Space Agency. I believe that a similar situation exists in the atomic propulsion of submarines, for example.

Mr. FELDMAN. Earlier in your testimony you stated that it was desirable for the new Space Agency to take over all space activities of other agencies in the civilian field. Would you include the Atomic Energy Commission program in this connection?

Dr. VAN ALLEN. I think my statement was that it should have primary cognizance.

It might well be that the Coast and Geodetic Survey would make important contributions in charts and so by primary cognizance I mean dominant control of policy and supervision of activities.

Mr. FELDMAN. That coordination you talked about previously could be done through liaison?

Dr. VAN ALLEN. I think the space Agency must have the necessary power to authoritatively request another Government agency to do work for it in accordance with its needs.

Mr. FELDMAN. And it should have the right to call on these various agencies?

Dr. VAN ALLEN. That is correct. For example, we may need a naval task force such as the Atomic Energy Commission needs for certain purposes. I think it should be clear that, at least through the President, the space Agency can authoritatively request and receive that type of operational support.

Mr. FELDMAN. Should the 1-million-pound thrust engine go to the new NASA or ARPA, or AEC?

Dr. VAN ALLEN. I think that would have to be threshed out. I believe its primary application is to space rather than to military uses and in my own judgment its development should be supervised by the NASA. But I think that sort of decision illustrates the type of decision which must be threshed out between the concerned agencies.

In my prepared statement I urge that in all cases of conflict of interest the decision be favored toward the NASA if it is a space undertaking.

Mr. FELDMAN. If I understand you, then, the new space Agency would be the primary determinant of what should be done. It would then have authority to go to the various agencies to have that function performed or call upon them to do the job; is that right?

Dr. VAN ALLEN. That is what I would urge. I think a major decision such as this one may well need to be decided by the President or by the National Security Council.

Mr. FELDMAN. Would you make the Agency head a member of the National Security Council?

Dr. VAN ALLEN. Yes, sir; I would.

Mr. FELDMAN. No further questions.

Mr. KEATING. That is what I was going to ask.

Do you not think that the importance of this new Agency is such that either the director or the chairman of a commission should have a voice in the formulation of policy at the very highest level?

Dr. VAN ALLEN. Yes, sir; I think he will be a major administrative official of the Federal Government without a doubt.

Mr. KEATING. I am glad to hear you say so in such a forthright manner.

And he should either sit with or be a member of the National Security Council?

Dr. VAN ALLEN. Yes.

Mr. KEATING. Should he not sit in and be present at Cabinet meetings?

Dr. VAN ALLEN. I should think so.

(The prepared statement of Dr. Van Allen follows:)

STATEMENT OF PROF. JAMES A. VAN ALLEN, DEPARTMENT OF PHYSICS, STATE UNIVERSITY OF IOWA, IOWA CITY, IOWA

1. Purposes of a national program of space research

Mr. Chairman and members of the committee, the purposes of a national program of space research are several:

(*a*) Basic investigation of the phenomena of nature on a geophysical and astrophysical scale,

(*b*) Development of civilian and technical applications of the new knowledge and techniques resulting from (*a*),

(*c*) Human adventure,

(*d*) Development of military applications of the new knowledge and techniques resulting from (*a*).

The advancement of the prestige of the United States among nations is often given as a purpose of our space program. Yet I prefer to regard tangible achievements as the purposes with the confidence that such achievements will naturally lead to whatever level of prestige is appropriate.

2. Basic scientific investigation

Basic knowledge must precede the development of means for serving human needs and desires. Outer space is a vast region of human ignorance.

Hence, in my judgment, our national program during the next several years should emphasize the investigation of fundamental geophysical and astrophysical phenomena. During the past 12 years, vertically fired sounding rockets have been quite fruitfully applied to this undertaking; they continue to possess great value in making possible studies within the earth's atmosphere and at such sufficiently high altitudes as may be regarded for certain purposes as above the atmosphere. The firing of sounding rockets should be regarded as an important aspect of a continuing national space program.

But satellites are vastly superior vehicles for investigations which require prolonged observations at high altitudes and for those which require the survey of geophysical phenomena over vast areas of the earth and over great ranges of altitude. In addition, satellites offer certain unique advantages not possessed in any measure by other techniques.

As residents of the earth, our greatest interest doubtless centers upon the physical conditions on the earth and in its astronomical environment.

Our national program in the immediate future should emphasize the thoroughgoing investigation of conditions pertaining to the earth. In due course, corresponding investigations of the moon and of other planets should be undertaken.

3. Development of civilian and technical applications

It is reasonable to expect that applications of new geophysical and astrophysical knowledge will be numerous and important to the welfare of our citizenry. Possibilities for greatly improved weather forecasting and for high-speed communications can already be foreseen with confidence. In addition, there will doubtless be far-reaching advances in the electronic and mechanical arts. And not the least of the benefits of a vigorous space effort will be in providing a great new impetus to education and to cultural and intellectual endeavor in the United States. There is already ample evidence of this tendency.

4. Human adventure

It appears that most scientific observations in space can be most efficiently conducted by automatic equipment in the near future. There will eventually come a stage in the complexity of desirable equipment when the judgment, discretion and intuition of human operators will be mandatory.

For this reason and for the further reason of satisfying the strong urge for human adventure and exploration, systematic preparations should be made for flying men in space vehicles. Such preparations should comprise physiological, psychological, and medical laboratory experiments. The flight of men should be preceded also by a progressive series of flights of biological specimens and living animals with accompanying apparatus for observing and reporting their functions and reactions.

5. Military applications

There will likely be many useful military applications of the results of space research. But, in my judgment, a much broader and more fruitful national program will result if the program objectives are not set by the demonstrated needs of military weapons systems and of other military applications.

6. The proposed National Aeronautics and Space Agency

I heartily endorse the intent of H. R. 11964 in establishing a national space agency, as an operating civilian agency of the Federal Government. In the establishment of such an agency, I feel that it is essential that it be given dominant cognizance, among all Federal agencies, of matters pertaining to space research, developments and operations. Only in this way can a long-range national program be developed for the maximum benefit of our citizenry and for the advancement of our national welfare. The Military Establishment can contribute in many ways to this endeavor and in turn will benefit by it. But as a matter of national policy, I deeply believe that civilian management and primary cognizance will best serve the long-range national interest. In addition, such an arrangement emphasizes, before the world, our primary interest in the peaceful exploitation of space and will greatly facilitate arrangements for international cooperation. Such cooperation is of great practical value (as witness the extensive international network of stations for observing IGY satellites) and is of prime importance in leading to peaceful and mutually helpful international relationships.

7 Funding of civilian space research

The establishment of a National Aeronautics and Space Agency will be a hollow gesture indeed unless it is funded on a scale commensurate with its national role.

The present IGY satellite program in the United States is estimated to have required about $150 million. This effort is evidently only a small beginning in space research. It is therefore apparent that a vigorous NASA which is capable of carrying the dominant Federal role in space research, development, and operations must be funded at a yearly rate of the order of $500 million. Any lesser support will not permit accomplishment of the clear legislative intent of H. R. 11964.

8. Activation of the NASA

In order that the NASA can be placed in full-scale operation as rapidly as possible it appears that the following measures should be taken as soon as enabling legislation and appropriations permit:

(*a*) Transfer to NASA of all facilities, personnel, and activities of the National Advisory Committee for Aeronautics.

(*b*) Transfer to NASA of all such facilities, personnel, and activities of other Federal agencies, including those of the Department of Defense, which are concerned primarily with the exploratory and peaceful aspects of space.

(*c*) Transfer to the administration and supervision of NASA all contractual activities of other Federal agencies which are concerned primarily with the exploratory and peaceful aspects of space.

(*d*) Establish, under NASA administration and supervision, laboratories, proving grounds, firing ranges and international observing networks for the primary purpose of the national civilian space endeavor.

In due course, it may be desirable to consolidate many of the scattered activities which are contemplated in the above But this need not be done in the first instance

9 Relationship of the NASA to the Department of Defense

In the above it has been urged that the NASA be given dominant cognizance, among all Federal agencies, in the exploration and peaceful applications of outer space. The national security requires that the activities of NASA not adversely affect the development of specific weapons systems and the accomplishment of other short-term, specific military objectives Decisions on the proper cognizance of areas in which a conflict of interest with the Department of Defense exists should be made, in general, in favor of the NASA—unless a clear and significant loss of military preparedness can be demonstrated to result thereby.

Mr. NATCHER. The committee will recess now until 2:15 this afternoon.

Thank you very much, Dr Van Allen.

Dr. VAN ALLEN. Thank you, Mr. Chairman.

(Thereupon, at 12 25 p. m., the committee was recessed, to reconvene at 2:15 p. m., same day.)

AFTERNOON SESSION

The committee reconvened at 2:15 p. m., upon the expiration of the recess.

The CHAIRMAN. The committee will be in order.

The next witness is Rear Adm. W. F. Raborn, Director of Special Projects of the United States Navy

We are very happy to have you with us, Admiral. We appreciate the important work that you are doing. You have a very vital assignment in the national interest of our country.

You may proceed, Admiral.

STATEMENT OF REAR ADM. W. F. RABORN,[24] DIRECTOR, SPECIAL PROJECTS, UNITED STATES NAVY

Admiral RABORN Thank you, Mr Chairman. It is an honor and privilege to appear before your committee.

I hope that what I have to say will prove of interest and possibly some help in your very important work in organizing a national space committee for space exploration.

I would like to confine my remarks and remain somewhat in the field in which I am working because I do believe that the type of work which we are doing will have to be done to some degree in any space exploration project that is set up for our country.

I have had the pleasure of briefing Dr. Roy Johnson who is engaged in this type of work for the Secretary of Defense and I am happy to say that he plans to utilize some of our techniques in managing a large complex program in his own shop.

First, I should like to say that it is my personal belief that the NACA provides an excellent foundation on which to expand the responsibilities of that organization for space exploration. I think with participation by all three services that that organization is probably the best on which to build and in which to entrust this most important work.

In the Navy we have a deep and abiding interest in subjects in which any space exploration body would engage, particularly in the lines of navigation, reconnaissance satellites, high-speed aerodynamics, upper-air research, and so on.

There is one thing I should like to point out which I believe may or may not have been given the thought that possibly it should. That is the close environment between the nuclear-powered submarine and a space vehicle.

A nuclear-powered submarine that goes below the surface of the water and remains there for days on end must provide inside of it quite a number of things which must be provided for in a space craft which would be inhabited by humans or living animals.

[24] Raborn, William Francis, Jr., naval officer; b. Decatur, Tex., June 8, 1905; s. William Francis and Cornelia Victoria (Moore) R.; B.S., U S Naval Acad , 1928, student Naval War Coll , 1951-52; m Mildred T Terrell, Apr. 5, 1955, children—Barbara Raborn Richardson, William Francis III Commd. ensign USN, 1928, advanced through grades to rear adm , 1956, designated naval aviator, 1934, assigned battleships, destroyers, aircraft carriers, 1928-40; established Aviation Gunnery Sch , Barbers Point, Pearl Harbor, T.H., 1940-42, exec. officer U S.S. Hancock, Fast Carrier Task Forces Pacific, 1943-45, chief staff Comdr. Task Force 58, Comdr Carrier Div 2, Western Pacific, 1945-47; operations officer Comdr for Air West Coast, 1947-49, research and development guided missiles Bur. Ordnance, 1949-50; dep. dir. guided missile div Office, Chief Naval Operations, 1952-54; comdg. officer U.S.S. Bennington, 1954-55; asst. chief staff Comdr., Atlantic Fleet, 1955; 1st dir. Navy's Fleet Ballistic Missile Program, Baptist, Mason. Home 4121 N. Randolph St., Arlington 7, Va. Office· Bureau of Ordnance, Dept. of Navy, Washington 25.

I should think it would be a source of some comfort to any space organization up for development of these matters to see the work that the Navy is doing and to recognize this as a ready vehicle in which to do some elementary exploratory research.

As you know, our nuclear-powered submarine has to sustain life and sustain life on a high operating level of efficiency. It is necessary that the officers and men aboard these submarines be in topflight physical condition and operating efficiency, both mental and physical, if they are to do their job and do it well.

So the Navy has for many years attempted to improve the environment inside our nuclear-powered submarines, and I am very glad to say that we have made remarkable progress in the last few years.

My own office, concerned as it is with the Polaris submarine, which is a nuclear powered submarine, is quite heavily engaged in technical and scientific pursuits along these lines.

It does not take much imagination or thought to recognize that the physiological and psychological elements which enter into efficient human operations of a nuclear powered submarine are quite real and free.

I have two full-time medical officers, captains in the United States Medical Service, who are engaged in this work in my office full-time, and are heading up a navywide project to better the environment inside the submarine.

I am delighted at the progress which we are making.

I should like to say a few words, if I may, about my organization because I do believe that some of the techniques, managerial techniques, which we have rather successfully employed will be of distinct interest to any other organization which will engage in high-priority work.

As you know, Mr. Chairman, we have had a refreshing new approach to running or managing a top-priority project or work.

The CHAIRMAN. How long ago did that develop?

Admiral RABORN. We started this into effect when I took over this job a little over 2 years ago. I was given the highest priority job within the Navy and told to get it done, that no one is going to tell me how to do it; that I was to be the boss.

Now, this is a rare privilege and also a tremendous responsibility.

I am very happy to say that because we were not inhibited by previous ways of doing things and because we were singularly oriented as to what we were trying to do, we were not hampered by previous organizational concepts or methodology.

So, under the impetus of a truly challenging technical problem, a truly challenging weapon-system concept which offered to the country a distinct addition to their national arsenal, we were able to attract and utilize the services of some of the best technical minds in the uniformed personnel of the Navy, as well as in the Government service civilian organization. They clamored for an opportunity to go to work on this because of these two challenges.

Recognizing that we were trying to do something that has never been done before, and this will be somewhat the position that the head of the new space agency will find himself in, it appeared that we should give our people in the Polaris program maximum responsibility and authority to do their job.

In other words, our secret in being ahead of our program schedules I think can be summed up by saying we got good people, gave them plenty of authority, plenty of guidance, but we did not hamper them.

I was the buffer and I am still the buffer to my people and we try to keep other folks from bothering them.

This is not magic and it is not something new. But one of the things we have evolved which is of interest to any organization trying to get a job done is the type of management technique which we have evolved, as I said before, and which is refreshingly new.

It takes old concepts and puts them together in a distinctly different way.

I am very happy to say that this has attracted attention not only within the three services and has been adopted in whole or in part, but has met searching scrutiny of business firms. There are more than a dozen large firms in the United States and many more smaller ones which have adopted our business management techniques for directing high priority technical work.

Dr. Livingstone, of the Harvard School of Business, spent 2 days in my shop following his appearance before Senator Johnson's committee. He asked our permission to utilize a portion of the techniques in his school. This we were more than happy, of course, to acquiesce in.

If it meets the concurrence of the chairman, I should like to show this on the screen and possibly paint a little better picture than I can do verbally. [Slide.] The purpose of the management team of the special projects office of the Polaris program director. We are to build a Polaris missile; we are to build the nuclear-powered submarine; we are to test the entire system.

The job includes selection and training of the personnel and to provide a completely operational team to the fleet. In other words, for the Polaris submarine missile system.

My office has total responsibility and total authority. We work through existing organizations and this is one of the things I should like to bring to your attention, if I may.

It is quite important, to prevent pyramiding on top of the existing organizations, to utilize those organizations and laboratories which have talent. It has the advantage of going into those organizations and using them only to the extent which your work requires.

As your work needs to expand in the various organizations, laboratories, and so forth, they can accept it if they have the priority.

My office is relatively small.

As you see here, it is divided into three major normal divisions [Slide.] Director of plans and programs, which includes fiscal matters and facilities. It is a resource branch. It provides the plans. It provides the money, the guidance, overall facilities, and so forth.

The Technical Division whose job it is to do the technical research and development necessary to provide the entire weapon system. That includes the missile and submarine and all associated equipment.

And the Director of the Administrative Division.

The CHAIRMAN. To whom do you report?

Admiral RABORN. I report to the Secretary of the Navy, sir.

The CHAIRMAN. Direct line?

Admiral RABORN. Yes, sir; direct line. [Slide.] The special projects management team is a small management team which integrates and

directs the fleet ballistic missiles efforts of over 125 Government agencies and private contractors. These lines leading to this symbol are roughly some of the areas in which we are interested.

It covers the country. It is complex and complicated.

This is where and why really we had to evolve a management system which would be effective and which would allow all parts of the system to be kept in step, if you please.

We went to American Management Association—I did, personally, with some of my people—we spent 3 days there listening to various members of the better-run companies in the United States tell in detail how they gave good management to their companies.

We made tours to some of the better known companies, better recognized from a management standpoint. We went into some detail with their management people and we found no one system which would be applicable to what we were trying to do.

So, necessity being the mother of invention, in this case, we sat down and evolved this sytem which I will try to explain a little bit more fully to you, one which I think will be of help to any space exploration director. [Slide.] Basically when we got the job of doing the full weapons system we sat down with the leading technical people from the many corporations and laboratories that had a major input.

Lockheed missile system division for the missile. The Bureau of Ships, of course, that is going to build the ship for us. The customer, the Chief, Naval Operations, had two representatives. Massachusetts Institute of Technology which was providing, of course, the missile guidance. The Atomic Energy Commission of course, for the warhead. Naval Ordnance Laboratory for fusing, and so forth. The General Electric Co., shipboard fire-control system, and to do the production of the missile guidance. The Aerojet-General Corp. who was to provide the missile motors. The Westinghouse Electric Corp. doing the launching and handling for the submarine. Sperry Gyroscope and North American for shipboard navigation.

We broke down our study groups into these major elements of the part of the missile system and studied our problem for 3 long months.

I am very proud to say this because so many people I am sure are not acquainted with the detailed and painstaking studies which go into a successful project.

Before we started handing money out to our contractors we studied our problem for 3 long months and each in concert with the other, optimizing each of these items by itself and then in relation to the other because what we wanted to do was to have an optimum submarine system.

Polaris missile submarine system: We tried to forecast the technical state of the art some 3 to 5 years in advance and said, because we are sure we can do this 3 to 5 years from now let us strive to set our goals and do these things with these performance characteristics.

This is what is termed in our parlance as the envelope philosophy. We set the physical characteristics that had to be set, the weight, the size, dimensions of the missile, for instance. With that being set we could build the launch and handling gear for the submarine

With the physical characteristics of other elements of the weapons system we could then develop in concert, lock arm in arm and walk forward together in the development of all elements of the weapons system of which the major elements are shown here. [Slide.] To

enable us to do this job this management system, technique of directing this organization, was centered in what we called our management center. That is a room the physical characteristics of which we evolved. These charts are of our own design and which attracted widespread attention.

Basically this is a workshop; this is a tool to help do our job. In this, of course, is centered all the plans, the coordination techniques so necessary in order that decisions made in one area of this weapon system can be made with full knowledge of its effect on other parts of the weapons system.

This is the way you make progress in a hurry and space exploration should, of course, be vigorously pushed. [Slide.] One of the key things which allows a technical group or a director of a project to walk fast, run, if you please, with widespread interest which must be coordinated, is to bring together your top people and as many of them as you can on a regular basis.

I do this every Monday morning. We dedicate every Monday morning to a complete breakdown of the significant events of the past week and its relations with each part of the program.

I get 75 people in here. I have representatives from all my outlying offices, from my major contractors, and any contractor who has a reason to be there, such as the fact he might be a little slow in meeting his schedule.

And the gentlemen in my office responsible for each of their major areas get up and tell their story in front of the entire group. So the level of knowledge and learning of the entire group is brought up to a very high level in the major significant elements of the weapons system, each one of them.

I allow one officer an hour and a half in order that he might take his particular program apart in some detail and spread it out in front of the rest of the group.

Thus we have at a month and a half intervals a complete rundown of everyone else's major interest in some great detail [Slide.] Now, the thing which we have evolved, which has been widely copied, is a charting means. It is new. We attempt to use one chart to show the major elements of any good management system.

If you were the director or the boss of any business, you would like to have some assurance that good planning has been done all the way down the line for the number of years that you are interested in a project. You would like to know that you have a means of trying to feel progress or lack of it.

You would like to have a means of communication of ideas between you and your contractors. All of these are very important elements.

In my visiting of American business firms I found that these major management techniques were utilized in different forms; one man being sick in one organization, no one could even decipher the form, they could not tell me.

This is not a good state of affairs and what we have done is choose a form which would allow us to show evidence of good planning, would provide us a ready means to measure progress, or lack of it, to provide us a ready means of communicating with our contractors.

Briefly in this box we would say the job that has to be done, the investment or cost which would have these components which would be produced in this period of time.

25973—58——57

Responsibilities, direction, supporting, and monitoring of contractor are clearly defined for each item, the actual milestones for doing these things which we have by collective staff action shown up here.

The dates go here, and to serve these purposes. We use this as the four major elements of good management.

[Slide.] This is one filled out, the Polaris missile.

We have broken it down between propulsion, reentry body, flight controls, structure, and auxiliary equipment, missile checkout equipment, system integration, and guidance. [Slide.]

What is 1 line on this chart, the missile, can be broken down in propulsion in 6 more planning charts, 6 more charts to gage your projects, 6 more charts on which you can establish communications with your contractors.

So you break down each of these subareas into smaller subareas. Every week my boys give me a quick snapshot view. We are all busy and at this Monday morning conference the man gets up and says, "My highlights for the week. I am in good shape in all my major work except in one place, in this case a minor weakness which has to do with something or other."

This is a dummy chart so it does not mean much. [Slide.] Shown on this chart then are the four major areas, major chartings which we have provided in some detail.

Now, these are sensitive planning charts. They are milestones of establishing progression, a means of communications, evaluation of progress. [Slide.] Now, we get into the techniques known as the line of balance. Many people do not like to bother with these things because they do not like to work with details.

Yet if you are going to do something in a short period of time, you have to be bothered with a lot of things that you probably would like to ignore. So we have utilized the line of balance technique.

In essence, these are the major elements on these lines of the Polaris missile and the length of time, so many weeks it takes for each of these elements to commence their fabrication, commence their initial design, assembly, and so forth.

And at any one time you can lay your ruler down and you should have accomplished everything underneath it or to the left of it, and the line of balance or these vertical bars for each of these subsurfaces.

If you are up to this line which you have set there for yourself as your goal you are in balance. If you are not, you are out of balance. It is that kind of thing which gives you a detailed feel of the progress of major items of equipment and subitems. [Slide.]

For instance, this is a first state motor which was one line on that other chart. It becomes eight lines here. This is just one stage. [Slide.] These are not very glamorous, but they are distinctly revealing. This is the second stage motor. [Slide.] These are additional charts. I do not expect to try to read them.

This is for a gyro; this is maintained by the Lockheed missile division and he checks on his subcontractors way down the line.

I would like to show you one thing which has created much interest lately [Slide] This is a shot recently off San Clemente about 2 weeks ago in which we for the first time fired a full-scale Polaris missile from underneath the water This gives you one of the many side rings going on in this circus at all times which is the coordination that you

must have right at your fingertips if you are to develop, for instance, in this case, the launcher that goes aboard the submarine.

So we keep track of things of this kind and the progress of it.

This shows the missile having been fired out of the water depths.

The CHAIRMAN. How far does that picture show it is up?

Admiral RABORN. The missile is here and it has been ejected at this point.

Mr. McDONOUGH. What distance does that travel?

Admiral RABORN. I am sorry, sir; that is classified.

Mr. KEATING. Are those boats around that thing?

Admiral RABORN. Yes, sir; but that is some distance away. It is about a mile.

Mr. KEATING. You mean the closest boats are a mile?

Admiral RABORN. Yes, sir; these are buoys, you see.

I will give this as a sample of the kind of operations going on continually in widespread fields, extremely complicated.

That launcher below the water hooked up by coaxial cables underwater to this barge over here is the finest example I have seen of heavy shipyard work and beautiful intricate electronic techniques of instrumentation. It is a rare combination.

It exercised the Navy's talents almost across the board. We had undersea frogmen for instance, that were working below the water at some depths, working on the various gear that goes below; underwater television, underwater cameras, high speed cameras, underwater instrumentation.

It was really a complicated thing. This is just one ring in a multitude ring circus going on at all times which must be dovetailed into the overall program.

This Polaris program, as you know, is considered by most people as the most complicated weapons system we have today.

Mr. KEATING. Is it classified as to how far below the surface of the water the submarine is?

Admiral RABORN. Yes, sir. I shall be glad to tell you separately, sir. I shall be glad to try to answer any questions.

I hope my remarks have been helpful.

The CHAIRMAN. Have you completed your statement?

Admiral RABORN. Yes, sir.

The CHAIRMAN. I have here a news item that appeared in the Boston paper on April 11 on that underwater missile firing. It says:

> The Navy said today it has developed the equipment to fire the Polaris 1,500-mile range ballistic missile from underwater as a solution of the problem of getting into the air where its rocket engine can ignite.

I am reading from the paper now.

Admiral RABORN. Yes, sir.

The CHAIRMAN. That is not classified, is it?

Admiral RABORN. Some very well educated guesses are made from newspaper stories.

The CHAIRMAN. It also quoted you as saying that the launching device and actual hardware is under daily test even before the missile carrying submarines are built; is that right?

Admiral RABORN. That is correct.

The CHAIRMAN. In other words, the Polaris is being tested, but you and your associates are so confident about the success that the

going ahead and building of the submarines is a proper calculated risk to take?

Admiral RABORN. Yes, sir; and this I am glad to say is shared by the Secretary of Defense scientific advisory committee on missiles.

They have put themselves in writing to this effect.

The CHAIRMAN. It says here "1,500-mile range". Can you answer any questions on that?

Admiral RABORN. I will be pleased to within security bounds, sir.

The CHAIRMAN. Is it known that it can go 1,500 miles?

Admiral RABORN. No, sir.

The CHAIRMAN. Is it felt that it can go 1,500 miles?

Admiral RABORN. We are confident that it eventually can; yes, sir. That is no magic range, either. That is no magic limit either.

The CHAIRMAN. Do you view the Polaris weapon system as an alternative to the use of satellites?

Admiral RABORN. If I understand your question correctly, Mr. Chairman, could the Polaris missile be used for satellite work?

The CHAIRMAN. Yes, or as an alternative.

Admiral RABORN. The propulsion system and the Polaris missile is perfectly capable, properly instrumented, I am sure, of placing a useful load in orbit. That is, when it is developed. We do not have it yet.

The CHAIRMAN. Can you give us any information as to the target date?

Admiral RABORN. Mr. McElroy has said he expects to have the missile and the submarine operational in the fall of 1960.

This, of necessity, of course, would mean that we would have the missile sometime before that.

The CHAIRMAN. Coming back to the NACA, you say it is probably the best upon which to build and to entrust this important work. You gave us very powerful evidence, very pointed evidence, as to the importance of management.

Of course, in connection with any new agency that might be established that same question applies.

Admiral RABORN. I would think that to be successful in the development of exploratory work the techniques of good management would be paramount.

The CHAIRMAN. And the primary duty of whoever is in the new agency will be different from that of the past?

Admiral RABORN. If I read the bill correctly, I would think so.

The CHAIRMAN. There would be no reason to establish it unless it were so?

Admiral RABORN. Yes, sir.

The CHAIRMAN. They have been pretty plainly tied up to aeronautics in the past?

Admiral RABORN. Yes, sir.

The CHAIRMAN. Now, they are going into the space field with all its implications, and those who are appointed to administer any agency that is established have to be men of vision and dynamic leadership, men of understanding as well as ability, and not men with a status quo mind?

Admiral RABORN. Those are my beliefs, sir.

The CHAIRMAN. Do you think that men who have been connected with this organization to date, which has been in existence since

around 1915, by reason of their limited, while important, use, while limited in important fields, might tend to have a status quo mind?

Admiral RABORN. I am sure, sir, without attempting to weasel on the answer to that question, that you will find people with status quo minds everywhere. I would think along with new responsibilities in the space age, the NACA could well take in some new blood.

The CHAIRMAN. I am not talking about NACA as an agency to be the foundation. I am talking now about the leadership.

Admiral RABORN. My experience with NACA has made me quite respectful of their capabilities and their leadership.

They are doing some work for us now and we are very happy over the way in which they have responded.

The CHAIRMAN. Have you any views to express as to what form of organizational setup you think would be most effective, a single man at the head—call him a director or administrator—or a commission type?

Admiral RABORN. I believe that a director with considerable authority would be good.

I do believe, though, that he could well have a board of directors, if you please, to assist him in running an organization which would have such widespread technical interest.

The CHAIRMAN. You mean to advise him?

Admiral RABORN. To advise; yes, sir. To have some authority, but subject, of course, to the director.

The CHAIRMAN. If we did not name any board of directors by law you would assume that a wise administrator or director would seek the advice of others through the formulation of necessary committees or groups?

Admiral RABORN. Yes, sir; I would think so.

The CHAIRMAN. There are some who have expressed the opinion that by reason of the diverse activities that constitute outer space exploration a combination, say of five members, with members of the commission well qualified in different fields of activity, might be preferred to a single individual at the head.

What do you think of that?

Admiral RABORN. I would like to see a director put in with considerable authority. Someone who has to make the decisions. If you put the right man in this and give him the right kind of technical assistance in the form of a committee or advisory capacity or collateral authority capacity, but subject to the director, I think that would probably be the best way.

Of course, speaking from the military point of view, we are used to having bosses and yet the bosses that get along are the ones that make full use of their organization and the knowledge that is contained in the organization.

So I think it depends on whom you put in charge of it, really as to how well it works.

The CHAIRMAN. Nobody can ignore the force of that statement.

Whether it is a commission or individual, we could pass the most effective law in the works, if they are incompetent or uncertain or vacillating it would be administered poorly.

And if you have a weak law and good able men they will get the maximum out of it in administering the law. So no one can challenge that statement of yours.

However, I am wondering if the men who have been wedded to the past for many years, to one field like aeronautics, when suddenly shot out into a new and broad field, whether that enables them to have the vision or the outlook to give the required leadership in the new area.

Admiral RABORN. That is a very good question, Mr. Chairman. I can only give my personal views on that matter.

The CHAIRMAN. Will you give your personal views this way? I realize the question is a little embarrassing.

What kind of man do you think the civilian director should be?

Admiral RABORN. This is a tough question to answer from any point of view.

The kind of technical and scientific abilities which will make or break our country's space exploration borders on the true scientist who may or may not be interested in giving forceful direction to the necessary work to carry out the wonderful ideas and theories that he has. So it could well be that we could have an academy or group of distinguished scientists who could be freed to do the things which they are best able to do and that is to come up with scientific theories and scientific approaches which probably, if pursued vigorously, would be most fruitful, and support that man with a good managerial team.

You could take the details of running it off his shoulders.

I have such people in my office. I have true scientists who join men in being quite happy in doing the things which they are far more capable of doing than anyone else, yet they do not run the show.

But the smart director takes the ideas from these wonderful brains and utilizes them.

That, if you could find this combination, in 1 or 2 people, would be quite fortunate.

But you must have forceful direction or implementation, business-like techniques, in organizing and directing the scientific effort or you will fall by the wayside.

So you take the combination, the best business administrator and director in the country; without the wholehearted support of the scientific community you will get nowhere and anyone who is put into that job to assist in such technical direction and management of the project must have a due respect and deference to the scientific contribution of the distinguished men of science.

The CHAIRMAN. Assuming an agency is established, whether it is run by a director or commission, and it becomes law, what sort of civilian type work could this agency do in the immediate future as distinguished from the necessities of the military?

Admiral RABORN. Of necessity, the military thinking has been pointed toward something which they feel will be of distinct assistance to them in carrying out their military applications.

It is true they have a large number of technically and scientifically trained personnel and great talent. They usually have capabilities of giving good direction to technical programs.

By cooperation and for many other reasons they have been able to secure the services of many fine scientists to assist them in their rather narrow objectives.

But as I see space exploration, many, many things fall out which are of distinct value to the military in carrying out their traditional roles.

The CHAIRMAN. We know that everything the military has done has inured to the benefit of mankind. But in the immediate future

with the military necessity which confronts us, what would there be by way of original jurisdiction for a new agency to do?

Admiral RABORN. I think a new agency could best get together and formulate a national program to be parcelled out to existing agencies which would include civilian as well as military scientific agencies and laboratories to assist in the overall progress.

That is the coordination, the national coordination, giving top level direction and not having one or another service going off or concentrating solely on things which they have a normal right to do, of direct benefit to them and their country from their point of view.

I think this is one of the major contributions which a top level group of scientists can do, to formulate a national program.

The CHAIRMAN. Do you strongly support the establishment of an agency of this kind?

Admiral RABORN. Yes, sir; I do, Mr. Chairman.

The CHAIRMAN. I am asking for your own views, now?

Admiral RABORN. These are my own views.

The CHAIRMAN. You think it is in the national interest of our country to do so?

Admiral RABORN. Yes, sir.

The CHAIRMAN. A civilian agency?

Admiral RABORN. Yes, sir.

The CHAIRMAN. Mr. Keating, have you any questions?

Mr. KEATING. No questions, Mr. Chairman.

I have learned a lot from the admiral's presentation. Thank you very much.

The CHAIRMAN. Mr. Natcher?

Mr. NATCHER. Admiral, from time to time people point out to us that maybe we are not pooling our scientific knowledge with our allies, as we should. How do you feel about that in your particular assignment at the present time?

Admiral RABORN. I am afraid I am a little at a loss, Mr. Natcher, to answer that question because of these factors:

Our allies have not displayed too great competence—I do not mean this in a derogatory fashion, of course—in solid-propellent motor development, and the details of missile guidance and the details of the atomic warhead are, of course, by law restricted, restricted information. So, to pool our information with them would be a one-way flow to our allies rather than assistance coming this way.

They have displayed much competence in the technical field and I am the first to say that I would welcome, within the freedom given us by law, the exchange of technical information. This largely is being done.

Although I am not directly in this field this is my understanding. I get a continual flow from the other side and representatives from my office have gone on technical missions across the waters.

Mr. NATCHER. Do you believe one of our weak spots has been the result of our failure to put ourselves in a position to hold international scientific meetings? Now, what I have in mind by that, Admiral, is this:

As you and I well know, because of our ban as far as the Communists are concerned, it is impossible to hold meetings in this country since all international scientific organizations are open to all accredited scientific personnel regardless of political affiliation or belief or country and so forth.

On the other hand, according to the information we receive here in this country, Russia each month, maybe daily, is holding meetings in Moscow, and Moscow has thereby established itself probably as one of the scientific centers of the world. They are trying to establish themselves as the scientific capital of the world.

How do you feel, Admiral, from the standpoint of our holding more international scientific meetings in this country, about bringing these minds and these people together? Would it be to our advantage to take steps to correct this matter as far as such meetings are concerned?

How would it affect your particular assignment, or would it?

Admiral RABORN. It would not affect me to any significant degree, Mr. Natcher. I believe that the flow of interchange of technical information is now being carried out to a most acceptable degree between us and other countries. It is being done through many agencies which are classified and I do not care to mention them at this time.

One of the places where maybe we could do better, if such can describe the situation, is to advertise the factor a little bit more.

These large gatherings are primarily window dressing. The true scientist in this country and the true scientist of our allies, are collaborating on a daily basis.

So if you hold conventions, so to speak—I think this is what the Soviets do—it in effect is propaganda.

The true exchanges do not go on in conventions although in some substudy groups you might have a distinct advantage. But I believe there is a certain element of propaganda here.

Mr. NATCHER. The bill we have before us provides for the establishment of a National Aeronautics Space Board. Under this Board, composed of not to exceed 17 members, no more than 8 of the members of the Board shall be designated from appropriate departments or agencies of the Government, with at least 1 to come from the Department of Defense.

How do you feel, Admiral, about the particular Board consisting of 17? Is that too large? That is where you have a Director in charge and as to the divisions there, no more than 8 from the different departments of Government with at least 1 from the Department of Defense. How does that sound to you, Admiral?

Admiral RABORN. It sounds inadequate, Mr. Natcher.

Mr. NATCHER. What part of it sounds inadequate.

Admiral RABORN. The representation from the Department of Defense.

Mr. NATCHER. That is the point I had in mind, Admiral. Do you feel on this particular Board at least one member should come from each military service, or how much should come from the Department of Defense?

Admiral RABORN. I would think that at least one member from each of the military services. Although the Navy has not created too many headlines in space explorations, I did try to point out at the beginning of my remarks that in the true submersible, the nuclear-powered submarine, we are in effect engaged in splendid work today which will be directly applicable to space vehicles which must go outside this earth's atmosphere.

So I think all three services have a distinct contribution to make and have a distinct interest in what goes on in space.

The CHAIRMAN. Do you think they could be specified, or if we put 3 in, let the Secretary of Defense name the 3?

Admiral Raborn. I have confidence that the Secretary of Defense would name the right people. I would think that as long as the law is being drafted and being passed, that it would provide for representation from the three services, equal representation.

Mr. NATCHER. In other words, write it into the law. That would be the best way to handle it now?

Admiral RABORN. Yes.

The CHAIRMAN. One each from the Army, the Navy, and Air Force?

Admiral RABORN. Yes, sir.

The CHAIRMAN. What about the reorganization?

Admiral RABORN. I must plead ignorance about the reorganization.

The CHAIRMAN. This is a little reorganization, itself.

Mr. NATCHER. As I understand it you feel it would be better to make the necessary provision in the law, that is from the standpoint of the future and once and for all.

Admiral, I want to thank you for the fine statement you have made to our committee, and for your appearance.

Admiral RABORN. Thank you, sir.

Mr. NATCHER. I have followed your work somewhat. I want you to know that I think you are doing a fine job.

Admiral RABORN. Thank you.

The CHAIRMAN. Mr. McDonough.

Mr. MCDONOUGH. I have no questions. I think the Admiral has contributed a great deal in the answers to the questions put to him. I appreciate his appearance.

The CHAIRMAN. Mr. Fulton?

Mr. FULTON. How far have you gone on experiments on the reentry of a ballistic missile? Just generally, have you gotten pretty well along?

Admiral RABORN. Yes, sir; we are quite pleased with the status of technical development in those areas. We have them in hand.

Mr. FULTON. And on your guidance system is there a reasonable accuracy at the present time?

Admiral RABORN. We have not fired a missile with a guidance in it. We are in component development in guidance and the state of component development, the knowledge of the requirements of guidance, give us great confidence that it will be good performance.

Mr. FULTON. Actually, the missile could be fired with a directional guidance, either under water, from the surface of the land into the water, or from water to water or from land to land, air to air, as a missile?

Admiral RABORN. Yes, sir.

Mr. FULTON. So there is no real limitation of the Polaris missile similar to submarine type activity or the launching pad?

Admiral RABORN. We know of none.

Mr. FULTON. In general, you are redesigning the submarines so that they will have a different contour to be modern in respect to the Polaris missile, are you not?

Admiral RABORN. Yes, sir, we are; to accept the peculiar requirements of the missile system.

Mr. FULTON. That has been satisfactorily worked out at the present time so that it is practical?

Admiral RABORN. Yes, sir.

Mr. FULTON. The Polaris missile can be fired from under water, but has it yet been tested by firing under ice?

Admiral RABORN. No, sir.

Mr FULTON. As to the three submarines that are going up to the Arctic this summer for their exercises in August, do you intend to have any Polaris testing, or is that classified information?

Admiral RABORN. You are getting into classified waters, sir, if I may suggest.

Mr. FULTON. If the missile can be fired from a submarine, would it not be possible to have the missile's launching pads underwater or underground so that they could not be detected by any radar, sonar, or electronic means, and they could then be aimed at any particular target with ability in guidance, initial guidance. And in the Atlantic you would almost not need any ship, would you?

Admiral RABORN. These are technical possibilities. When you look at the technical desirability you run into a host of problems which would cause you not to do it that way.

Mr FULTON. There have been comments here by a previous naval officer to the effect that he thought there would be a danger in any waters from an unannounced submarine force with unannounced intentions. Is it classified, or could you give us about the area that would be?

Admiral RABORN. I am afraid I missed the point of your question.

Mr. FULTON. Suppose there is an unannounced submarine group coming toward the United States. At what point would it become a danger to us if its potentials were unannounced or we had no knowledge of it?

Admiral RABORN. Of course, it would depend on the capability of the submarine; whether it was purely a submarine equipped to attack surface ships or whether it was a missile-firing submarine or mine-laying submarine. There has been some comment on the 200 miles. I want to identify how and when.

Mr FULTON. But that is not far enough from our shores for the modern missile?

Admiral RABORN. You are speaking of original missile firing from submarines?

Mr. FULTON. We don't know what they are. But if a submarine came within 200 miles they would be too close to us. I think the danger point is further out in the Atlantic.

Admiral RABORN. It depends on the mission of the submarine. If it was a mining mission, naturally, they would come in, possibly, closer to get to our navigable waters on our coast and in the harbors, too. This would be a big threat. One or two mines could block a port.

Mr. FULTON. With the missiles coming into use and now being prepared, does it not move the point of danger to the United States pretty well to the middle of the Atlantic so far as the Navy is concerned?

Admiral RABORN. It does complicate our problem.

Mr. FULTON. We have to move out with additional range, then?

Admiral RABORN. Yes, sir.

Mr. FULTON. I want to compliment you on the development of the Polaris.

The CHAIRMAN. Mr. Ford.

Mr. FORD. I was delighted to see you do a fine sales job on your organization. I think it is an excellent organization. I have been down there, as you know, and have seen it firsthand. I am sure they will continue to do a first-class job.

Visualizing the work that this Agency will have to do, most of it in the initial stages of research and development, do you feel that the organization should have what we call no-year funds for its obligational authority in preference to 1-year authority?

Admiral RABORN. I would highly recommend that, Mr. Ford. The physical problems can well occupy too much attention, too much time of those who are trying to get a job done. No-year funds would certainly be a step in the right direction.

Mr. FORD. If you had to operate on yearly research and development funds, you would have quite a problem?

Admiral RABORN. It would be a highly inefficient operation.

Mr. FORD. Is there too much difference in the research and development program between what you are doing and what this Agency might be doing?

Admiral RABORN. That is correct, sir.

Mr. FORD. The Board is contemplated to have 17 members; 8 from the various Government departments, the remainder from outside. Is a board of that number too great? How do you feel about the number?

Admiral RABORN. I am afraid that I would feel, without too much study of the intent of the bill, it borders on the rather unwieldy, unless you can, maybe, structuralize those numbers into subordinate interests. But it is rather tedious to give everyone an equal vote and then have 17 people get together.

Mr. FORD. Do you have anything comparable to that in your organization?

Admiral RABORN. No, sir.

Mr. FORD. You are the director of the fleet ballistic-missile system, are you not?

Admiral RABORN. Yes, sir.

Mr. FORD. You have these board meetings or these conferences once a week?

Admiral RABORN. Yes, sir.

Mr. FORD. Where you have your various subheads and subcontractors meet with you?

Admiral RABORN. Yes, sir.

Mr. FORD. They are comparable to a board such as the one which you envisage here?

Admiral RABORN. In one sense, yes, sir, but, in another sense, no. I have three people who are my lieutenants, so to speak; the director of planning, who also has the physical facilities and other resources; the technical director; and my director of outlying offices. So, I narrow down to quite a handy and small working group to make decisions.

I never have more than 3 to 5 people on any one of the decisions. Those three people and I are really the corps of executive action.

The CHAIRMAN. So, you sort of create a commission within yourself?

Admiral RABORN. Well, I take my top lieutenants, as any commander does, and arrive at the proper decision, and the ultimate decision, of course, rests in me. I have to accept responsibility for the action, of course.

Mr. FORD. You are the Director, however?

Admiral RABORN. Yes, sir; I am the Director.

Mr. FORD. You have authority to exercise administrative authority and decision making?

Admiral RABORN. Yes, sir.

Mr. FORD. Do you think that is preferable to the commission type of operation on the civilian side?

Admiral RABORN. The scope and mission of this organization about which we are talking is a little different, actually, from what my mission is.

Mr. FORD. You have one thing to do, basically?

Admiral RABORN. It covers the waterfront, so to speak, and literally the United States. It is a wide, complicated thing. I am dedicated to one purpose.

Now, the proposed agency has a little broader field to cover. So I think that this being recognized, you could give considerably more thought to a little different organization from what I have, from an executive direction standpoint.

Mr. FORD. It seems to me it is important to have a director who has responsibility and authority?

Admiral RABORN. I agree with that, sir.

Mr. FORD. However, you set up or organize the board of directors or the adviser or whatever you want to call him?

Admiral RABORN. Yes, sir.

Mr. FORD. How do you feel about a term of office or an indefinite term for the director—the bill provides no set term—appointed at the pleasure of the President for confirmation by the Senate?

Admiral RABORN. I think the language of the bill would be desirable from my personal point of view. I would hate to see this change with administrations. I think they should be placed above such things and if the man has done a good job, he should be allowed to continue.

Mr. FORD. You do feel that at the present state of the art it is desirable to have more than one from the Department of Defense, probably 1 from each of the 3 services?

Admiral RABORN. All three services have a great deal to offer this new Agency and it would be desirable to have a direct representative.

Mr FORD. Is there any question about whether they should be military or civilian from each of the three services?

Admiral RABORN I really have no strong views on that, sir.

Mr. FORD. That is all. Thank you.

Mr. FULTON. Your bringing up the Director raises the question of how he would fit with the Department of Defense. On this point the question comes up that you could not fit your type of organization into the Department of Defense because it has within it the procurement right along with the research and development—and there is no procurement in the Department of Defense, is there?

Admiral RABORN. Not at present; no, sir. I believe Mr. Johnson has recently had that attitude here.

Mr. FORD. Through the ARPA organization?

Admiral RABORN. Yes, sir.

Mr. FULTON. Does it mean we set up a whole new system of procurement? Secretary of Defense Forrestal had recommended that the Department of Defense have a managing group of 100 people and it has ended up at about 5,000.

Should we try to insert in the Department of Defense some sort of relationship which will be a directing, guiding, or organizing group for this director, or should the Department of Defense merely have an overall supervision and then assign down to the forces the various developments?

Where would you put your directional control? Would you move it up into the Department of Defense, or would you leave the military end of it down with the three services?

Admiral RABORN. Stemming from this organization which I envision as purely a civilian organization but outside of the military department, the Department of Defense, I think it would be quite proper that the Department of Defense coordinate the activities of the three services in space exploration matters.

Mr. FULTON. They would simply assign the functions to be performed by the three services?

Admiral RABORN. Yes, sir, very much like they do now in the rest of the work.

Mr. FULTON. So that really on the military side you would set it up in that form rather than set up a whole new procuring agency along your lines in the Department of Defense; would you not?

Admiral RABORN. Yes, sir; that is my personal view.

Mr. FULTON. You would have your research and development function right down in the three services?

Admiral RABORN. Yes, sir.

Mr. FULTON. And be against it in the Department of Defense?

Admiral RABORN. Whatever coordinating capacity you think wise, of course, the Secretary of Defense could well use. But the three services are now set up and have good organization to direct the research and development. So I think in the interest of efficiency they would normally be used.

Mr. FULTON. You would suggest the civilian side not having a complete structure above what the operating mechanisms are—they are a rather simple organization—maybe a commission or a director under the commission or over the commission, a rather simple structure and a very efficient management structure?

Admiral RABORN. That would be very desirable from my point of view.

Mr. FULTON. Thank you very much.

The CHAIRMAN. Mr. Brooks.

Mr. BROOKS. Thank you, Mr. Chairman.

I came in late, Admiral, but I would ask you this: Would you adopt generally the idea of this Military Liaison Committee as you have it with the Atomic Energy Commission?

Admiral RABORN. I believe that would be safe. sir.

Mr. BROOKS. Would you do it by Executive order or by legislation?

Admiral RABORN. It does not really matter from my point of view as long as it is effected.

Mr. BROOKS. But you find that works reasonably well, do you?

Admiral RABORN. Yes, sir.

Mr. BROOKS. How do you feel about the Manhattan project that we had in the war?

Admiral RABORN. I am partial to that, sir. That is what I am leading right now, just about.

Mr. BROOKS. That is what I was going to say; you have a little Manhattan project yourself.

Do you think the best results can be attained that way?

Admiral RABORN. If you have a single purpose; yes, sir.

Mr. BROOKS. Single purpose and sufficient power in a single executive, too?

Admiral RABORN. Yes, sir.

Mr. BROOKS. Tell me, how large an organization do you have?

Admiral RABORN. For a year and a half I had 45 officers and 71 civilians in my home office. Now, because I have taken on the responsibility for these additional submarines and the continual growth in the development of machines, which I have responsibility for as well as the personnel, I am up to about 213 or 214 people today.

Mr BROOKS. That is a small organization at that?

Admiral RABORN. Yes, sir.

Mr. BROOKS. You are going to build the new submarine authorized by Congress?

Admiral RABORN. Yes, sir.

Mr. BROOKS. You actually will contract the job out?

Admiral RABORN. The Chief of the Bureau of Ships acts as a contractor for me for this purpose, but I am still responsible to the Secretary of the Navy for the efficient accomplishment of the construction of those submarines to do the Polaris job.

Mr. BROOKS. Does your supervision extend beyond the Polaris job—so far as necessary to accomplish a Polaris installation in a submarine?

Admiral RABORN. If I understand you correctly, sir, let me say that my responsibility encompasses the construction of the submarine and all its appurtenances, particularly those which are specially required for the missile system.

I am responsible for the development of the missile, testing it out and so forth, for the selection and training of the personnel, putting them all together, training them, and delivering them to the fleet.

Mr. BROOKS. You are given responsibility for a finished package?

Admiral RABORN. Yes, sir.

Mr. BROOKS To deliver the submarine staffed and trained and completely built and Polaris installed?

Admiral RABORN. Yes, sir.

Mr. BROOKS. You are responsible for the operation of Polaris, too?

Admiral RABORN. In doing this I would like to hastily add that we utilize existing bureaus and agencies of the Navy which have given fine cooperation.

Mr. BROOKS. Do you have authority to draw on the logistics division of the Navy, too?

Admiral RABORN. Yes, sir.

Mr. BROOKS. Can you draw selected personnel from them?

Admiral RABORN. Yes, sir.

Mr. BROOKS. To whom are you subject in order to meet your requirements?

Admiral RABORN. The Secretary of Navy.

Mr. BROOKS. No one but the Secretary can overrule your order for personnel or materiel?

Admiral RABORN. Yes, sir.

Mr. BROOKS. You really have a Manhattan project within the Navy Department.

Admiral RABORN. That is correct.

Mr. BROOKS. Do you account for the decided progress in the development of the Polaris because you have this type of setup?

Admiral RABORN. I am confident that it has been a major contribution to this, sir, but the key to it has been the full cooperation of the Navy Department and civilian contractors who are part of the team.

Mr. BROOKS. The entire Navy is behind it and wants to see a Navy project come through; is that right?

Admiral RABORN. They all recognize the importance of this in the national-defense scheme.

Mr. BROOKS. You said something I did not quite understand in response to my colleague, Mr. Fulton's, question about eliminating some vessels of the Navy. Did I understand you correctly?

Admiral RABORN. I am afraid I must have been misunderstood.

Mr. BROOKS. He suggested building submarine platforms from which the Polaris might be fired rather than the use of submarines or other vessels.

Admiral RABORN. The gist of that conversation, as I understood it, Mr. Brooks, was the thought advanced by some that possibly you could use submerged launchers located in various places off the coast in lieu of a submarine that can move around.

My answer to him was that while this might be technically feasible it certainly was technically and operationally undesirable.

They could be put out of operation easily by frogmen and so forth.

Mr. BROOKS. They would have the disadvantage of being immobile?

Admiral RABORN. Yes, sir, and roughly unprotected from frogmen.

Mr. BROOKS. The advantage of the Polaris is that it is mobile?

Admiral RABORN. Yes, sir.

Mr. BROOKS. It can be moved from place to place in comparative security?

Admiral RABORN. Yes, sir.

Mr. BROOKS. You have no authority for procurement, you say?

Admiral RABORN. Yes, sir, I have full authority for all procurement.

Mr. BROOKS. The Secretary of Defense under this new organization of advanced research does not overlap you?

Admiral RABORN. Of course we are all subject to the direction from the Secretary of Defense.

Mr. BROOKS. Well, are you?

Admiral RABORN. Yes, sir, I am. And my actions, when approved by the Secretary of the Navy, in turn, my requirements and desired actions are passed on by the Secretary of Defense who reviews them. When I get his approval we have total approval to proceed.

Mr. BROOKS. You really have two bosses, the Secretary of the Navy and Secretary of Defense?

Admiral RABORN. Yes, sir.

Mr. BROOKS. As long as the Secretary of Navy is happy, then, you only have to worry about the Secretary of Defense?

Admiral RABORN. Yes, sir.

Mr. BROOKS. That permits you to go ahead with maximum efficiency and the greatest possible results.

I want to ask you this: There was a speech made in the Southwest over the weekend in which the speaker, an official in the Defense Department, referred to the Russians as having made 17 attempts to reach the moon and failed.

Will you enlighten us upon that?

Admiral RABORN. I must plead ignorance, sir. I wish I knew, but I do not.

Mr. BROOKS. You are in a spot where you should know what is going on with guided missiles.

Admiral RABORN. I do know in my own shop and that is the limit of my responsibility and authority.

Mr. BROOKS. It does not cover everything on the Russians effort to reach the moon?

Admiral RABORN. My job is to beat them.

Mr. BROOKS. Even though they have made 17 attempts and failed, you are ready?

Admiral RABORN. We are going to make a try and make them work.

Mr. Brooks. I commend you for the progress you have made on Polaris. Do the features of the Polaris, which you have developed, make it possible to use that in competition with Jupiter, Jupiter-C, or the missile being used by the Navy, the Vanguard missile?

Admiral RABORN. You mean in space exploration, sir?

Mr. BROOKS. Yes, and missiles, too.

Admiral RABORN. The Polaris missile when developed can be used for land sites.

Mr. BROOKS. The Polaris can. But will it be competitive on land sites with, say, the Jupiter-C or the Vanguard?

Admiral RABORN. No, sir. Well, the Vanguard, of course, is not a missile per se, it is a research vehicle and it has been developed solely for getting things into orbit.

Mr. BROOKS. It may be used for a missile, may it not?

Admiral RABORN. I really don't know. It might, but it distinctly would not be efficient.

Mr. BROOKS. It has a small payload and therefore as a ballistic missile it is limited in possibilities?

Admiral RABORN. Yes, sir.

Mr. BROOKS. What about the Jupiter-C?

Admiral RABORN. This weapon, when it is developed, being a 1,500-mile ballistic missile, carrying a sizable payload, is quite adaptable for use from the land.

Mr. BROOKS. What about the Thor, Admiral?

Admiral RABORN. The same statement goes in connection with the Thor.

Mr. BROOKS. I missed a part of it.

Admiral RABORN. Would you like me to repeat my statement, sir?

Mr. BROOKS. Yes.

Admiral RABORN. When developed, the solid-propellent Polaris will be quite usable from land sites for ranges up to 1,500 miles.

Mr. BROOKS. And it will be competitive with the intermediate range missile up to 1,500 miles, whether it be land based or whether it be submarine based?

Admiral RABORN. If it is submarine based, it gets out of the intermediate-range ballistic missile field because you take it by submarine to distances you can fire the ICBM to and hit the same targets.

With respect to the end objective in hitting the same targets, it is a deterrent.

Mr. BROOKS. You could say the same thing for Thor if it were over in North Africa?

Admiral RABORN. Yes.

Mr. BROOKS. Or if it were somewhere in England or the same thing for the Jupiter-C?

Admiral RABORN. Yes, sir.

Mr. BROOKS. With a 1,500 mile range it would be the equivalent of an intercontinental ballistic missile?

Admiral RABORN. It is just another member of the deterrent family.

Mr. BROOKS. You do not think that other than that it will be competitive with an intercontinental ballistic missile, do you?

Admiral RABORN. That is correct. We are not building it except, as we hope, to be a very welcome addition to the ballistic missile family.

Mr. BROOKS. Placed in a forward area?

Admiral RABORN. Yes, sir.

The CHAIRMAN. And an important addition, too?

Admiral RABORN. Yes, sir.

Mr. FULTON. Could I clear up a misunderstanding?

The CHAIRMAN. Certainly.

Mr. FULTON. The point that you and the gentleman from Louisiana brought out is this, that actually a 1,500 mile missile from either side of a 3,000 mile ocean does not control the ocean. Mr. Brooks adequately pointed out the bases have mobility and I think the inference at the end of our questioning was that the Polaris missile on bases would be confined to places that are restricted waters or waters that have a firm defensive control.

Do you agree with that?

Admiral RABORN. Yes, sir. Fortunately the waters in which the Polaris submarine normally would operate are friendly or neutral waters and would not normally be traversed by sea and air force of any potential enemy.

Mr. FULTON. The strategic importance of the Polaris submarine could be shown by the fact that the 1,500 mile missile could cover practically the entire United States, on either side in range; and with the 1,500 mile missile we could cover 50 percent of the industrial area of Red China and Russia from the sea.

Admiral RABORN. Yes, sir. The sea areas outflank all land areas and with a 1,500 mile missile it is possible to cover practically every significant target in the world.

Mr. FULTON. So it is an outstanding and premium strategic weapon that has been developed by the Navy?

Admiral RABORN. We feel when it comes into being it will be.

Mr. BROOKS. In reference to the strategic value of course no one questions the strategic value of Polaris. It has the facility of moving from place to place.

But, on the other hand, I will say this, that you have to also realize that the Thor or the Jupiter-C have possibilities if placed in forward bases throughout the world, they will have a strategic value. That is true, is it not?

Admiral RABORN. Certainly.

25973—58——58

Mr. BROOKS. It is the old struggle between the land bases and the sea bases and you have that always with you.

Admiral RABORN. We like to think it is not. The submarine-launched Polaris missile, because of its mobility, complements rather than competes with land based missiles. It will be a significant part of our overall deterrent capability.

Mr. BROOKS. I think you are doing a marvelous job. The point I want to ask you though is this. A speaker over the weekend referred to the amazing progress being made in the development of solid propellents.

Can you enlighten us about any recent breakthroughs or progress made in the development of the solid propellents?

Admiral RABORN. There have been no recent breakthroughs in the propellent area. Basically, however, research is going on by all three services in this field and instrumental improvements are coming our way almost on a daily basis. The promise which solid-propellent motors have is largely based on projected ability to reduce the weight of the metal cases surrounding the propellent and which make up the motor in order that the propellent does not have to carry so much dead weight with it when it takes off.

Mr. BROOKS. You mean it does not have possibilities with the first section of the missile, but rather with use in advanced sections of the missile?

Admiral RABORN. It has possibilities in both. You can stage this quite readily. As a matter of fact, it has many advantages, particularly in the later stages. In the first stage, because the solid propellent motor being quite simple, once having been proved out, its ability to get off the ground when you want it to is very comforting.

Mr. BROOKS. It has a smaller possibility of getting out of order than the missile that uses in the first stage liquid propellent; isn't that true?

Admiral RABORN. That is correct.

Mr. BROOKS. Your development of the solid propellent is largely in the hands of private enterprise, is it not?

Admiral RABORN. We like to give full credit to the splendid work which our civilian contractors have done in this area, but I must say that the Army and the Navy together have been largely responsible for the initial research done in this area.

Mr. BROOKS. What about the advanced research that is being done now? Is that with the Army and Navy or private enterprise?

Admiral RABORN. It is being done by all three services now and also by private enterprise, which is quite alert to the attractiveness of getting in this field. I do not mean to depreciate the efforts of private enterprise in the solid-propellent research field, but the vision that put real money into the solid propellent development has lain with the Army and Navy, primarily, of military necessity.

They have put real money in it, and they have stimulated research to a very high degree.

Mr. BROOKS. What is going through my mind is how much can be placed in private enterprise and how much can be carried on by the armed services or the new agency that may be set up.

What would you suggest there?

Admiral RABORN. I think, sir, with the wide and deep reservoir of technical excellence and expertness in the three services, that they should be given really a lead in this.

I have people in uniform now that folks are trying to hire away from me every day. They would not be trying to hire them away if they were less expert than theirs.

Mr. BROOKS. Thank you.

The CHAIRMAN. Mr. Feldman.

Mr. FELDMAN. Admiral, I believe you stated that you did not inherit an existing organization and that when you started the Polaris project you started from scratch?

Admiral RABORN. Yes, sir.

Mr. FELDMAN. This project was for the single purpose of developing the Polaris and also putting it on atomic submarines; isn't that so?

Admiral RABORN. Yes; the entire Polaris weapon system, which includes the navigation part of it, the ability to do precise navigation, the development of launching techniques, peculiar needs in the submarine, including the missile.

Mr. FELDMAN. There is a distinction between this kind of project and space exploration projects such as the witness this morning, Dr. Van Allen, told us of. A new agency would have the problem of developing and building vehicles for exploring astronautics and also engaging in space investigation, rocketry, weather, communications, and so on. Each of these separate fields is a distinct part of the science but is a specialized function; is that not so?

Admiral RABORN. I think so.

Mr. FELDMAN. Consequently, a comparison between your type of organization and an organization which would be engaged in these activities might be a little different?

Admiral RABORN. It could be.

Mr. FELDMAN. You would want an expert, for example, on the building of space vehicles, and you would want another who was an expert in the field of astronautics, and one who was an expert in the field of communications as related to space exploration, and one who knew a great deal about rocketry, and another who would be expert in the field of weather?

Admiral RABORN. I think all those are elements of the problem; yes, sir. I also notice that they are common to my concern, too.

Mr. FELDMAN. And you do have experts in these various fields?

Admiral RABORN. I do.

Mr. FELDMAN. Not to the same scientific degree that these other fields would be involved in connection with space? There is a similarity. I recognize that.

Admiral RABORN. I have need for expertness in each of those areas and we are working on them. Let me say to clear this up—I do not want to confuse the picture—the space exploration should, of necessity, be considerably wider and deeper in scope than what the Polaris program encompasses.

Mr. FELDMAN. What I am leading to is this—even though it had a board or commission headed up by a single person, you would still require in that board or on that commission people who are experts in these various fields.

Admiral RABORN. Yes; indeed.

Mr. FELDMAN. It is a question of whether you would want on the Commission itself, or on the Board itself, people with these qualifications.

Admiral RABORN. They have to be connected with the organization and make their voice felt one way or the other.

Mr. FELDMAN. You have had a great deal of experience with the Atomic Energy Commission; is that not so?

Admiral RABORN. Yes, sir.

Mr. FELDMAN. Are you acquainted with the military liaison between the Atomic Energy Commission and the military?

Admiral RABORN. Reasonably so; yes, sir.

Mr. FELDMAN. That liaison in order to be effective has to be on a daily basis; does it not?

Admiral RABORN. Yes, sir.

Mr. FELDMAN. It has to be continuous?

Admiral RABORN. Yes, sir.

Mr. FELDMAN. The purpose of a liaison, of course, is not only to coordinate so that the right hand knows what the left hand is doing constantly, but it avoids duplication and a great many other hardships.

Admiral RABORN. Yes, sir; I think it does.

Mr. FELDMAN. And liaison should not stop with policy at the top; is that not so?

Admiral RABORN. That is correct.

Mr. FELDMAN. You in your organization, for example, see to it that liaison applies right down to the working level?

Admiral RABORN. Yes, sir.

Mr. FELDMAN. If you have a contract with a private company, you see to it that somebody in your organization is at that private company and keeps you informed of developments constantly?

Admiral RABORN. Yes, sir.

Mr. FELDMAN. That is very desirable. That is a type of liaison; is it not?

Admiral RABORN. Yes, sir.

Mr. FELDMAN. So that if such a provision were incorporated into the law, or into a proposal, it certainly would require constant and continuous liaison between the organizations involved?

Admiral RABORN. I think it would be very desirable, sir.

Mr. FELDMAN. Do you feel that a new weapons system like Polaris could have been assigned to NACA?

Admiral RABORN. No, sir.

Mr. FELDMAN. I am not talking about the new NASA; I am talking about the NACA.

Admiral RABORN. No, sir.

I do not think it would be appropriate.

Mr. FELDMAN. In other words, a big assignment requires a new and specially organized agency?

Admiral RABORN. I think every major task has to be objectively viewed to its special requirements and an organization set up to fit the specialized needs.

Mr. FELDMAN. I believe you also said earlier in your testimony that it is possible that NACA, because of its age, would have a certain amount of deadwood; is that not so?

Admiral RABORN. No, sir; I don't believe I made that statement.

Mr. FELDMAN. Well, you didn't use the word "deadwood." But I think you did say there might be people in an organization of that kind who might not be as effective as new people selected when you start on a new program?

Admiral RABORN. I think what I said, sir, was that I agreed that any organization is likely to have deadwood, including my own.

Mr. FELDMAN. Well, it is less likely to be in your own, because it is new; isn't that so?

Admiral RABORN. Yes, sir.

But we will weed them out if they show up.

Mr. FELDMAN. You indicated the NACA in order to do the new job would have to have a lot of new blood infused in it?

Admiral RABORN. Yes, sir. They will need additional talent and help.

Mr. FELDMAN. They would have to have additional talent in this new field?

Admiral RABORN. Yes, sir. They would have to have additional assistance.

Mr. FELDMAN. One last question, sir.

In connection with the development of the nuclear-powered submarine, a lot of new metallurgical problems arose; is that not so?

Admiral RABORN. Yes, sir. There were a fair amount. I am talking about the submarine proper, now.

Mr. FELDMAN. That is right.

Mr. RABORN. Yes, sir.

Mr. FELDMAN. As well as when the nuclear reactor was put in. You had to develop new weapons in order to house that new reactor?

Admiral RABORN. Yes, sir.

Mr. FELDMAN. And those were problems that were met and overcome?

Admiral RABORN. Yes, sir.

Mr. FELDMAN. Corresponding problems, of course, will arise in connection with the development of building of any new space ship that would have nuclear power; that would be nuclear propelled; is that not so?

Admiral RABORN. I think that there would be some problems there, yes.

Mr. FELDMAN. And they are not insurmountable?

Admiral RABORN. We hope not, sir. That is yet to be proven.

Mr. FELDMAN. No further questions.

The CHAIRMAN. Any further questions by any members of the committee?

(No response.)

The CHAIRMAN. Admiral, coming back to the representation on the Advisory Committee, general Advisory Board, it says there shall be at least one from the Defense Department. It does not limit it to one. You understand that, do you not?

Admiral RABORN. Yes, sir.

The CHAIRMAN. And the President could appoint 3 or 4 or 5 if he wanted to.

Instead of prescribing for three members of the Defense Department, don't you think it would be better to have that flexibility where the President could use his judgment?

Admiral RABORN. Well, I am sure whatever judgment the President of the United States would use would be adequate, sir.

The CHAIRMAN. Thank you very much, Admiral.

We appreciate the valuable testimony you have given.

For myself as chairman and all the other members of the committee, I express to you our sincere thanks.

Admiral RABORN. Thank you, sir. It has been a pleasure and an honor to be here.

The CHAIRMAN. The next witness is Dr. Francis W. Reichelderfer, Chief of the Weather Bureau of the Department of Commerce.

Doctor, we are very glad to have you with us today. Have you a prepared statement?

Dr. REICHELDERFER. I have some notes, Mr. Chairman. I understood that the committee was interested primarily in estimates on, and the additional values to, business, industry, and agriculture of perfect weather forecasts.

This is a highly hypothetical question. I can answer questions or make a general statement on it, if you wish.

The CHAIRMAN. Whichever you prefer.

You may make a general statement on the subject, and the members of the committee will probably want to ask you some questions.

Dr. REICHELDERFER. Thank you, sir.

STATEMENT OF DR. FRANCIS W. REICHELDERFER,[25] CHIEF OF THE WEATHER BUREAU, DEPARTMENT OF COMMERCE

Dr. REICHELDERFER. Some 10 or 15 years ago the Weather Bureau undertook to determine the value of weather forecasts and storm warnings to the general public and to the national economy. We took a sampling and hoped we could arrive at a fairly accurate estimate.

However, the figures that were presented to us by business and agricultural interests were so high that we never have been quite willing to come out with the values for fear that someone might think we were exaggerating.

They were well in excess of a billion dollars a year. Now that gives some starting point for determining, for estimating, the value of weather forecasts and storm warnings if one were able to predict definitely and exactly several days ahead.

They would be that much more valuable if one could predict accurately several months ahead. Here are some recent estimates that were produced in certain fields, representative of certain fields, after I found that the committee was interested in figures of this kind.

For example, the university extension service of one of the States estimates that $5 million would be added to farm income in that State alone if forecasts for a period of 5 days or so were 100 percent accurate.

For farming in general, the figure that was given to me is $2½ billion a year.

For the lumber industry, $45 million.

[25] Reichelderfer, Francis Wilton, chief U. S. For transportation, exclusive of air transport, $100 million.

In the very important field of water resources, the planning of how to handle water stored for irrigation, in the light of what the weather will be a few days or a few weeks ahead, the estimate is $3 billion a year.

Retail marketing values would be great. Certainly on the order of $50 million or $100 million per year.

Now, these figures are all tentative, Mr. Chairman. No one can tell what could be developed in the application of weather information, weather reports and forecasts, if these reports and forecasts were as definite and specific, for example, as the tables of solar eclipses, lunar eclipses, and so on.

We feel quite sure that the figure would be several billion dollars a year. So much for figures.

As to what this has to do with the subject under discussion: I understand that this estimate was brought into the discussion because of the likelihood that satellites, artificial satellites, would be used to survey the atmosphere, give us hourly or bihourly pictures of cloud systems and storm systems all over the globe, as one means of filling the gaps in our information now.

I should say parenthetically that weather forecasts are not unsatisfactory because the forecaster is indifferent or incompetent but because he has to work with very inadequate data.

We have relatively little information of conditions in the high atmosphere, conditions that undoubtedly have a bearing on the weather. From vast areas in the oceans and in the polar regions we get only very inadequate reports.

So, there are great gaps where severe storms can form and move in toward the land without the meteorologist, without the weather forecaster, knowing much about them in advance. By use of photographs taken from the satellite, it will be possible to get up-to-the-minute reports, or up-to-the-hour reports, of the development of storms at sea, their movement toward the coast, and in this manner give much more definite information as to when they will strike, what their intensity will be, how large they will be, and how long they will last, and other information of that kind that is vital not only for the protection of property and for the protection of life but also to avoid the very great expenses that are connected with preparations in marginal areas where the storm doesn't strike.

Not only will we be able to give weather advice leading to positive protection, but we will enable business and industry to avoid preparations that cost, in many cases, hundreds of thousands of dollars that are unnecessary just because they have to do it to play safe.

Some of the gulf industries have given estimates as to how much it costs them to prepare for a hurricane. And, in many cases, they prepare only as a precautionary measure, not because the hurricane is expected to strike there, but because of some possibility.

The satellite, Mr. Chairman, will be used eventually, I feel quite sure, in a still more fundamental meteorological measurement. That is to determine how much energy the sun pours into the weather machine every day. At the present time, we have no way of knowing how much energy or the fluctuations in energy that reach the atmosphere.

And, as you know, the reason we have weather is that the sun heats the air over the Equator faster than it heats the air over the poles. It sets up an inequality and a circulation that, expressed very simply, gives us, in general, our day-to-day weather changes and the averages that we call climate.

The CHAIRMAN. Does that activity come under this new Agency?

Mr. REICHELDERFER. No, sir. I presume not. I think that I was called here, primarily, to show that the development of the work under this Agency is of primary concern to the Weather Bureau and to the development of meteorology.

The CHAIRMAN. Would sending up satellites and so forth come under this Weather Bureau or this new Agency?

Dr. REICHELDERFER. The Weather Bureau would hope to be able to include in future satellites a meteorological unit compatible in all respects with other elements that are sent up in a satellite.

We have no intention of getting into the business of manufacturing satellite vehicles or rockets. This is not intended. But we do have such a large stake in what can be done with future satellites that the relationship between the Weather Bureau and this new Agency should be clearly understood. Of course, we are one of many. The Coast and Geodetic Survey is another agency that would be very much interested in the mapping that can be carried out from the satellite.

The CHAIRMAN. Is it the intention of the Weather Bureau to project a satellite of its own?

Dr. REICHELDERFER. No; it is not.

The CHAIRMAN. The Weather Bureau would utilize the Space Agency? The Space Agency would carry out this experimental work, and then the Weather Bureau would be given the benefit of it. You would carry on from there?

Dr. REICHELDERFER. That is quite true.

The CHAIRMAN. Just like anything in research that inures to the benefit of the military; then, so far as weapons are concerned, the military will take over.

Dr. REICHELDERFER. Yes.

The CHAIRMAN. I see the distinction.

How long have you been Chief of the Weather Bureau?

Dr. REICHELDERFER. Eighteen years, sir.

The CHAIRMAN. You have been connected with the Weather Bureau prior to that?

Dr. REICHELDERFER. No. I was a naval officer prior to that.

The CHAIRMAN. That is very honorable service, and I am aware of the great service you have rendered. Have you completed your statement?

Dr. REICHELDERFER. Well, one of the interests, also, is in connection with weather control. We do not know a great deal about the possibilities of using the information that would be developed through this new Space Agency in connection with weather control. We do know, however, that the Agency would be expected to produce basic-research data which must be part and parcel of any plans for weather control, whether it is very limited, local weather control, with a modification, or whether it gets into the bolder plans to control the weather on a large scale.

The CHAIRMAN. Mr. Brooks.

Mr. BROOKS. Doctor, I want to say, too, that I have observed your work for many years. I recall when we first took up with you the

matter of setting up a program of ferret out, locate, and warn of tornadoes in the Southwest. I think you have done a magnificent job in that respect.

You have testified on the important economic values of knowing something about what is going to happen in the weather. In coming to the program that we have here, Doctor, which is the space vehicle, what sort of instruments would you expect to set up? You would have a photographic arrangement to take pictures. You have said that. What else would you set up in a satellite to give you some assistance in reference to your work?

Dr. REICHELDERFER. There presently is a design—in fact, the instrument is just about completed—to measure the radiation that is received from the sun and the outgoing radiation from the earth.

You see, the sun sends a wide spectrum of energy, which is, some of it, intercepted by the earth. A little of it is absorbed by the air as the rays pass through. More of it is absorbed by water vapor and by cloud particles. Most of the radiation goes on through to the ground. It heats the ground, and some of the radiation, on a much longer wavelength, is radiated back into space.

Now, it is the balance between the incoming and the outgoing that determines how much the atmosphere is heated. This is of basic importance not only in any mathematical approach to the general circulation of the atmosphere which determines our storms, but, also it is important in determining whether the climate is getting warmer as a whole, and why.

This, as you can see, leads directly into questions of preventive measures and possible weather modification. This radiation instrument is the second experiment that would be put on the satellite. It is quite possible, also, that it will be found that some of the phenomena being discovered under the program of the International Geophysical Year will have some bearing on weather. Just within the last few days there was an article about the energy, the radiation, in the night sky aside from the radiation from the stars.

Now, it does not appear that this will have much effect on weather. But we do not know. It is another factor that has just been discovered. And it is conceivable that, in the long run, we will find that this is another element that enters into the surprises that we have in climate and the day-to-day weather changes.

Mr. BROOKS. What do you mean by that particular phenomenon there, the energies in the night sky?

Dr. REICHELDERFER. This press release is just new, and I do not have all of the information, but it is assumed that some of the energy put out by the sun is refracted or reflected around the earth and is present at nighttime when the surface of the earth on the night side is shielded from the sun. And this is something new. This we didn't know of before. It has not been fully explained. It seems to be too small in amount, too slight in intensity, to have any effect. But we cannot say that it has no effect until we know more about it.

Mr. FULTON. That is the Navy research and development finding you are speaking of?

Dr. REICHELDERFER. Yes, sir.

Mr. FULTON. It is a form of light so far that has been invisible?

Dr. REICHELDERFER. That is right.

Mr. BROOKS. The radiation you refer to, is that nuclear radiation that we refer to in atomic power and energy?

Dr. REICHELDERFER. No. I was referring primarily to the radiation from the sun all through the visible spectrum and above and below the infrared and ultraviolet, rather than the type of radiation we have in mind when we speak about radioactive fallout.

Mr. BROOKS. Now, what else do you expect to get from that possibility of utilizing the satellite?

Dr. REICHELDERFER. We do not know what the eventual possibilities will be.

Certainly the most important and the most tangible now are the hourly and bihourly surveys of storm systems completely around the globe, an improvement that might very well bring a new epoch in meteorological understanding. That is the most important. The second is the radiation measurements of energy from the sun and from the earth.

Mr. BROOKS. What about the importance of learning more about the effect of the moon on the weather?

Dr. REICHELDERFER. This, certainly, could be studied. The moon, like the nighttime radiation that I just mentioned, appears to be of relatively little importance in determining weather. I know there are many sages who would dispute that. But we do not find any physical, direct physical, relationship between the moon and the weather.

Mr. BROOKS. Did you find any in reference to the effect of the moon on the tides, especially the high tides?

Dr. REICHELDERFER. Yes; that influence is very direct.

Mr. BROOKS. Would that have any monetary value?

Dr. REICHELDERFER. Well, it certainly could have; yes. There have been various attempts to develop tidal power. I believe the tides are being used for power in some limited localities.

Mr. BROOKS. Now, let me ask you along a different line: You say you can discuss the weather, but cannot do much about the weather. But I have read a lot about weather control

Is there a possibility that you may get into this situation and learn something about the control of the weather?

Dr. REICHELDERFER. There is legislation now pending before Congress to authorize the National Science Foundation to carry on further basic research in weather modification.

The Weather Bureau is directly interested, because some of these experiments will undoubtedly have a bearing on the forecasting of the amounts of rainfall and snowfall—quantitative precipitation forecasts, we call it. This is really very important not only in irrigation projects and flood control, but in warning the public what preparations should be taken in critical situations.

In the floods in Pennsylvania, during the Easter weekend, there was some danger that the waters would exceed the height of the dikes and that there might have to be large-scale evacuation. Now, we were able in this case to predict satisfactorily what would happen so that unnecessary large-scale evacuation was avoided.

But our methods of predicting the amount of rainfall are still far from perfect. We are quite confident that the experimental studies and the research into weather modification will have a direct application in our forecasting of the amount of precipitation.

Mr. BROOKS. Over the weekend, I think night before last, they had 10 inches of rain down in my section of the country.

And they told me up in Texarkana—Texas and Arkansas—the precipitation exceeded 12 inches. The city water supply rose 3½ feet inside of 1 night; so, there is a hazard there.

But do you think there is a possibility of controlling those extreme precipitations in the event you become involved in the space situation?

Dr. REICHELDERFER. We have to look at this whole thing with a very broad view.

Relatively little is known about the general circulation. I hesitate a bit, because we do know many things about the formation of storms, their movements and development. But there is much more to be known.

And until we know all of the factors that enter into the regulation, the determination of how the atmosphere behaves, until we know that, we will not be able to say how far we can go in weather control.

We know that there are many things that can be done. Weather is controlled to a certain extent at the present time in the orchards where the horticulturalists use orchard heaters to prevent frost.

I think we have hardly scratched the surface.

And the knowledge that comes from seeing the atmosphere from above as would be the case with the satellite will certainly give us a scope, a comprehension of what goes on that we have never had before. We are optimistic about the possibilities.

Mr. BROOKS. Would it be fair to say that if this thing will lead to the possibilities of even limited weather control, the financial or monetary benefits are incalculable; is that correct?

Dr. REICHELDERFER. That is correct. I am quite sure that the monetary value would run into several billions of dollars a year.

Mr. BROOKS. If you could relieve us of floods down in the lower Mississippi Valley it would save us a lot of money.

Dr. REICHELDERFER. The National Science Foundation is the general research agency that, it seems to me, should logically carry on the weather modification studies. Now, you have asked specifically about the NASA.

The present National Advisory Committee for Aeronautics has for many years carried on certain special studies in meteorological problems of the NACA. And we have helped carry out these studies—the NACA has carried on studies dealing in particular with gusts, wind gusts, and their effect on aircraft structures.

They have carried on many studies on icing of aircraft and icing in carburetors. So the NACA, I think, should continue to carry on special studies in meteorology that have to do with aircraft and with craft that will travel outer space.

But I do not believe that the NACA or the NASA would be the agency to carry on the general research in weather modification.

I think that is not contemplated. We have unusually good coordination among all of the interested departments in matters of meteorology. The agencies work together fairly closely without duplication and in many respects as one weather agency.

For example, the Weather Bureau uses the weather reports from the Air Force, from the Navy, from the Coast Guard. And they are all put into this general pool of information that is developed for use on the daily weather map which you see posted in one place or another.

Specifically with reference to your question, I don't believe the weather-modification aspects should be in the NASA.

The CHAIRMAN. All your testimony would be more pertinent to the National Science Foundation than to this new agency?

Dr. REICHELDERFER. Except that the new Agency will have, I understand, the responsibility for the satellites where we would get our source information.

The CHAIRMAN. I misunderstood you, Doctor. You wouldn't have the NASA, the new Agency, established with broad jurisdiction, with emphasis on the outer space, and the National Science Foundation competing with reference to satellites or instruments going up into outer space for the purpose of ascertaining the various things you have spoken of.

Dr. REICHELDERFER. No. I see no need for competition. I don't think there would be.

The CHAIRMAN. In other words, the new NASA would have an important function in connection with your testimony with reference to weather control and all of the other aspects you referred to; the NASA would play an important part in ascertaining the information or the discovery.

Dr. REICHELDERFER. It would have an important function in making it possible for us to get the basic data, viewing the atmosphere from outer space.

The CHAIRMAN. In other words you wouldn't have 2 agencies like the 2—I will call them agencies—the National Science Foundation and the NASA—competing with one another in connection with the development of the propulsion to send satellites up into the air.

Dr. REICHELDERFER. Not at all; no, sir. This phase of the weather organization that you have just referred to is a common one. For example, it would be absurd for the Weather Bureau to have ships in the ocean to gather weather reports.

Instead we gather the reports from ships that are there for another purpose.

Now, the satellite will be sent up for general purposes. And what we want again is to get a ride to get the weather reports we need without becoming a space agency ourselves.

The CHAIRMAN. Mr. Metcalf.

Mr. METCALF. No questions.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. Doctor, as I understand you, there would be a number of economic benefits to be derived not only by the people but also by the Weather Bureau as a result of the establishment of this new Agency.

Dr. REICHELDERFER. Yes, sir.

Mr. NATCHER. As you probably know, the NACA would go out of existence on the effective date of the NASA. Do you know of any arrangements that the Weather Bureau now has with the NACA that would be affected to the extent that they couldn't be transferred over to the NASA.

Dr. REICHELDERFER. I know of none. I would suppose that the new Agency would find it necessary to have interdepartmental groups of one kind or another, committees, and the work that the Weather Bureau is interested in could continue under that same arrangement.

Mr. NATCHER. Doctor, during the years of 1953 and 1954 we didn't

have much rain down in Kentucky. Since that time we have had a whole lot of rain and the winters are much more severe. Maybe it is because I am a little older, but I feel the cold more.

Do you believe any of this has been brought about as a result of our testing of our atomic weapons and hydrogen weapons and our ballistics missiles—any change in the weather?

Dr. REICHELDERFER. We have a unit working in cooperation with the Atomic Energy Commission that has that question in mind more or less constantly. This unit follows the progress of radio-active clouds and keeps very close track of what happens in the atmosphere as a result of the radio-active fallout.

There is no evidence up to the present time that there has been a change due to the atomic bombs or the hydrogen bombs. The unusual weather, that you just referred to, is the usual thing in weather. You can go back to the records 75 or a hundred years ago, and there will be a series of years very dry and relatively warm, and then a series unusually cold.

And this happens in one place or another all of the time. It is the thing that makes my profession very interesting. There is never a dull moment in trying to keep track of these things.

But I think it is quite sure that up to the present time there have been no large scale, no worldwide, effects from atomic bomb explosions.

We have no doubt that if they were numerous enough there would be an effect. But I think our problems would be other than weather if that were the case.

Mr. NATCHER. Thank you very much.

I also want to thank you for the fine statement you made to our committee.

Mr. FULTON. Doctor, could you put into the record the estimate of the damages you said would be saved on advance warning of hurricanes and tornadoes? Also the estimate on the prevention of flood damage through advance warning.

You commented on those two things.

That is all.

(Material referred to follows.)

1. *Hurricane warning service.*—The present accuracy of hurricane warnings annually saves on the average 900 lives and $100 million in property damage. With completely accurate hurricane warnings issued sufficiently far in advance to permit full-scale precautionary measures, an additional 80 lives and $50 million in property damage could be saved. In addition, completely accurate hurricane warnings would save an estimated $10 million annually in unnecessary preparations for hurricane conditions which are forecast but do not occur.

2. *Tornado warning service.*—The present accuracy of the tornado forecast and warning service annually saves on the average 110 lives and $10 million in property damage. With completely accurate tornado forecasts 3 hours in advance, an additional 170 lives and $5 million in property damage could be saved.

3. *Flood warning service.*—The present accuracy of the flood warnings annually saves on the average 420 lives and $30 million in property damage. With completely accurate flood warnings 36 hours in advance, an additional 70 lives and $30 million in property damage could be saved. In addition, completely accurate flood warnings would save an estimated $5 million annually in unnecessary preparations for floods which are forecast but do not occur.

The CHAIRMAN. Mr. Ford.

Mr. FORD. Doctor, is the Weather Bureau getting any information now from our three satellites which are orbiting; that is, peculiar to the Weather Bureau?

Dr. REICHELDERFER. We are interested, of course, in the temperatures that are sent down, the temperature inside the satellite and the temperature of the skin.

This has no direct bearing so far as we know on our immediate problems of meteorology.

Mr. FORD. Does the Weather Bureau have any part in putting equipment within the satellites?

Dr. REICHELDERFER. Not at the present time. But within the program, within the Vanguard program, it is expected that there will be specific meteorological devices in some of the future launchings. And the Weather Bureau working through the International Geophysical Year does have a device for the radiation measurements that I mentioned.

The cloud-scanning device is being provided by one of the military services—the Signal Corps.

Mr. FORD. Does the Weather Bureau have any connection or has it had any in the past, with NACA.

Dr. REICHELDERFER. Well, we work very closely with NACA. The Chief of the Weather Bureau is ex officio a member of the NACA.

Mr. FORD. Of their Board?

Dr. REICHELDERFER. Of the 17-man Board that is true. I have sat with them for many years.

Mr. FORD. Do you sit with them in their regular meetings which we understand take place 8 to 10 times a year?

Dr. REICHELDERFER. I do, yes.

As you doubtless know the composition of the committee itself changes from time to time, from year to year. And it has at the present time a rather broad representation of different interests. And I would think that the new Agency patterned along that line would include in its membership representatives from some of the fields that will come to the forefront—astrophysicists, and others that will be interested in the outer space aspects of the responsibilities of the new Agency.

Mr. FORD. Do you feel that a board composed of members with a broad view, putting them all together, contributes to the direction and the action of an agency such as NACA?

Dr. REICHELDERFER. I do. Serving as sort of a board of directors, this committee over the years has brought in new blood from time to time, and they have on the whole a very forward look in the development of aeronautics.

I think it has worked out remarkably well.

Mr. FORD. Even an agency such as the Weather Bureau, which superficially you wouldn't think would have much to contribute to the hardware aspects of the NACA, has made a real contribution to the Agency.

Dr. REICHELDERFER. Yes, sir. Of course the NACA's responsibilities include applications of aerodynamics, and this has to deal with the atmosphere.

The NACA deals with the aerodynamics aspects, and we are dealing with the meteorological aspects of the atmosphere.

So there is a closer connection than one might think initially.

Mr. FORD. In your own shop do you have an advisory board of any sort composed of people within and without the Government.

Dr. REICHELDERFER. Not a continuing board. During my tenure

in the office, I have had advisory boards, special advisory boards, from time to time.

At the present time the National Academy of Sciences has a Committee on Meteorology that was organized 2 years ago on my recommendation through the Undersecretary of Commerce for the very purpose of taking a forward look in the possibilities and the future developments of meteorology and advising the Bureau.

This Board is headed by Dr. L. V. Berkner. And the committee has published one interim report.

Mr. FORD. That is advisory rather than supervisory, as far as your office is concerned?

Dr. REICHELDERFER. That is right.

Mr. FORD. That is all.

The CHAIRMAN. Mr. Feldman.

Mr. FELDMAN. Just one question, Doctor.

I want the record to be clear on this. I know it is repetitious, but it is repetitious for the sake of emphasis. That is, the savings in dollars and cents will be in excess of several billion dollars per year if we have accurate weather forecasting?

Dr. REICHELDERFER. It certainly would be several billion dollars a year. And when one stops to think that with a gross national product of—what is it—around 400 billions now?—and when you take the whole run of weather—snowstorms, droughts, floods—with weather affecting almost every human endeavor, certainly 1 percent difference in profit or loss for the gross national product as a whole would be very, very conservative.

That is $4 billion. So I would say in excess of several billion dollars.

Mr. FELDMAN. Have you any idea at all of how many lives are lost each year due to failure to have accurate weather forecasting?

Dr. REICHELDERFER. I can give some figures on that. I can give certainly the order of magnitude now and can correct them in the record, if I may.

Years ago before we had the present hurricane warning service, there was an average of 900 to 1,000 lives per year lost. That number was reduced to normally a score, or so.

Now, at the moment the figure is all askew because of the terrible disaster at Cameron, last year.

The forecasts there were quite good. There were other problems on evacuation.

As for tornadoes, the loss of life still runs between 150 and 200 per year. But in the recent tornado at Wichita Falls, Tex., there was one life lost, and local representatives make it quite clear that if it hadn't been for the warnings, that there would have been a loss of many more—perhaps scores.

The same is true of the Fargo tornado last summer. There were good warnings. The people went to their cellars or took shelter otherwise. And undoubtedly scores of lives were saved through those warnings.

Mr. FELDMAN. It is safe to say then, that if we had accurate weather forecasting many lives would be saved which would otherwise be lost.

Dr. REICHELDERFER. There is no doubt about it.

The CHAIRMAN. Any further questions?

(No response.)

The CHAIRMAN. We thank you.

Without objection there will be inserted in the record a memorandum prepared for the members of the select committee by our director and chief counsel, George J. Feldman, and the other members of the staff.

That will be put in the record at this point.

(The memorandum follows:)

SELECT COMMITTEE ON ASTRONAUTICS
AND SPACE EXPLORATION,
HOUSE OF REPRESENTATIVES,
Washington, D. C.

MEMORANDUM

To: Members of the House Committee on Astronautics and Space Exploration.
Subject: National Advisory Committee for Aeronautics.

I am submitting for your perusal a concise description prepared by the staff of the origin, duties, and functions of the NACA.

Much of the material was obtained from the Library of Congress, which has also compiled a summary of significant changes in the practices and relationships of the NACA and the National Aeronautics and Space Agency proposed by the administration. A copy is attached, along with the text of the basic NACA law.

GEORGE J. FELDMAN,
Director and Chief Counsel.

THE NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS

The NACA is a permanent, independent, executive agency, which reports directly to the President. It was established by Congress in 1915. The language authorizing its creation was part of the Naval Appropriations Act. It authorized the expenditure of $5,000 a year "or so much thereof as may be necessary," for 5 years, the money to be spent for experimental work, investigations, clerical expenses, supplies, etc.

Since then, Congress has provided for the NACA the most modern research equipment at a total cost of more than $300 million. Its present operating staff numbers 7,600 scientists, engineers, etc., of whom over 2,000 have professional degrees.

The duty of the NACA, in brief, is "to supervise and direct the scientific study of the problems of flight with a view to their practical solution."

In more detail, its duties and functions, as outlined by law, are as follows:

Duties (50 U. S C. 151b):

"Under such rules and regulations as shall be formulated by the Committee, with the approval of the President, for the conduct of its work, it shall be the duty of the Committee (1) to supervise and direct the scientific study of the problems of flight with a view to their practical solution (2) to determine the problems which should be experimentally attached, and to discuss their solution and their application to practical questions, and (3) to direct and conduct research and experiments in aeronautics in the Langley Aeronautical Laboratory, the Ames Aeronautical Laboratory, the Lewis Flight Propulsion Laboratory and in such other laboratory or laboratories as may, in whole or in part, be placed under the direction of the Committee."

Functions (50 U. S. C. 151b):

"The National Advisory Committee for Aeronautics is authorized—

"(a) to equip, maintain, and operate offices, laboratories, and research stations under its direction,

"(b) to acquire additional land for, undertake additional construction at, and purchase and install additional equipment for, existing laboratories and research stations under its direction; and

"(c) to purchase and maintain cafeteria equipment."

(Aug. 8, 1950, ch. 645, par. 1, 64 Stat. 418)

The NACA operates the following facilities:

Langley Aeronautical Laboratory, near Hampton, Va.; a pilotless aircraft research station, Wallops Island, Va., Ames Aeronautical Laboratory, Moffett Field, near San Francisco, Calif.; the Lewis Flight Propulsion Laboratory, Cleveland, Ohio, and a high-speed flight station, Edwards Air Force Base, Calif. The laboratory at Cleveland has cost up to $110 million to date and employs about 2,800 people

The top governing body of the NACA is a 17-member committee, sometimes referred to in the organization as the "main committee." Its members are appointed by the President and serve without compensation, except for per diem pay and expenses. Ten members represent specified Government agencies, while the remaining members are selected from "persons acquainted with the needs of aeronautical science either civil or military, or skilled in aeronautical engineering or its allied sciences." Nongovernmental members serve 5 years.

Following is the current list of NACA members:

Allen V. Astin, Ph. D., Director, National Bureau of Standards.
Preston R. Bassett, D. Sc.
Detlev W. Bronk, Ph. D., president, Rockefeller Institute for Medical Research.
Leonard Carmichael, Ph. D., Secretary, Smithsonian Institution (Vice Chairman).
Frederick C. Crawford, Sc. D., chairman of the board, Thompson Products, Inc.
William V. Davis, Jr., vice admiral, United States Navy, Deputy Chief of Naval Operations (Air).
James H. Doolittle, Sc. D., vice president, Shell Oil Co. (Chairman).
Paul D. Foote, Ph. D., Assistant Secretary of Defense, Research and Engineering.
Wellington T. Hines, rear admiral, United States Navy, Assistant Chief for Procurement, Bureau of Aeronautics.
Jerome C. Hunsaker, Sc. D, Massachusetts Institute of Technology.
Charles J. McCarthy, S. B., chairman of the board, Chance Vought Aircraft, Inc.
Donald L. Putt, lieutenant general, United States Air Force, Deputy Chief of Staff, Development.
James T. Pyle, A. B., Administrator of Civil Aeronautics.
Francis W. Reichelderfer, Sc. D., Chief, United States Weather Bureau.
Edward V. Rickenbacker, Sc. D., chairman of the board, Eastern Air Lines, Inc.
Louis S. Rothschild, Ph. B., Under Secretary of Commerce for Transportation.
Thomas D. White, general, United States Air Force, Chief of Staff.

The "main committee" meets on an average of once monthly, although the law requires only two meetings a year. During its first 10 years (1915–25) its activities were largely advisory. Since then, however, its chief responsibility has been the conduct of aeronautical research.

The Chairman (and Vice Chairman) of the NACA are elected by the committee. They serve 1-year terms.

Dr. Hugh L. Dryden is the Director. He was selected in 1947. He was then Associate Director of the National Bureau of Standards. His task is to "execute the policies and direct the activities of the Committee." He is "the head of the agency in all matters except those which by law or regulation require action by the Chairman." He receives $20,000 annually.

The Executive Director is John F. Victory, who has been with the NACA since 1915, being its first employee. He is the assistant head of the agency and his task is to "supervise and direct its administrative work."

The Associate Director for Research is John W. Crowley, Jr. His job is to "supervise and direct the scientific and technical activities of the agency."

These are the three officials who perform the actual work. The Committee itself functions as an unpaid board of directors, providing, to quote Crowley, "general direction, policy guidance and inspiration."

The Chairman of the NACA, James H. Doolittle, is apparently the sole officer who has access to the President on matters concerning the operation of the agency.

According to Dr. Dryden, "the Committee meets monthly to discuss research programs and budgets, to survey the present problems and forecast the future problems confronting aircraft designers and operators and the military services, and to initiate the research necessary to meet the needs."

Assisting the Committee in the determination of policy are 5 major and 22 subordinate committees, whose members also serve without compensation, except for per diem pay and expenses. These committees, according to Crowley, "recommend and review the research programs underway and yet to be undertaken" They help maintain effective teamwork among the various governmental and private agencies and the aircraft industry. The total membership of the various committees is more than 400.

25973—58——59

The most important committee in the NACA, other than the "main committee," is the Executive Committee, composed of seven members elected by the Advisory Committee for 1 year. In addition, the Executive Committee includes any member of the Advisory Committee "resident in or near Washington and giving his time wholly or chiefly to the special work of the Committee."

The Executive Committee "shall control the administration of the affairs of the Committee, shall have general supervision of all arrangements for research, and other matters undertaken or promoted by the Advisory Committee * * *. This body is also headed by a Chairman and Vice Chairman, elected by the Executive Committee.

The following committees and subcommittees assist the Advisory Committee in its coordination of aeronautical research and the formulation of its research programs:

Committee on Aerodynamics (including subcommittees on fluid mechanics, high-speed aerodynamics, aerodynamic stability and control, automatic stabilization and control, internal flow, low-speed aerodynamics, seaplanes, and helicopters).

Committee on Power Plants for Aircraft (including subcommittees on aircraft fuels, combustion, lubrication and wear, compressors and turbines, engine performance and operation, powerplant controls, powerplant materials, and rocket engines).

Committee on Aircraft Construction (including subcommittees on aircraft structures, aircraft loads, vibration and flutter, and aircraft structural materials).

Committee on Operating Problems (including subcommittees on meteorological problems, icing problems, flight safety and aircraft noise).

Industry Consulting Committee (which provides advice on policy matters affecting the aircraft industry).

Special Committee on Space Technology (established January 1958). This committee is headed by Dr. H. G. Stever, associate dean of engineering at the Massachusetts Institute of Technology. Other members include:

H. Julian Allen, Ames Aeronautical Laboratory.
Dr. Hendrik W. Bode, director of mathematical research, Bell Telephone Laboratories.
Dr. Milton U. Clauser, director of aeronautical laboratory, the Ramo-Wooldridge Corp.
Prof. Dale R. Corson, Cornell University.
James R. Dempsey, manager, Astronautics Division, Convair.
Robert R. Gilruth, Langley Aeronautical Laboratory.
S. K. Hoffman, general manager, Rocketdyne division, North American Aviation.
Dr. W. Randolph Lovelace, II, Lovelace Clinic.
Dr. William H. Pickering, director, Jet Propulsion Laboratory, California Institute of Technology.
Dr. Louis N. Ridenour, Jr., Missile Systems division, Lockheed Aircraft Corp.
Abe Silverstein, Lewis Flight Propulsion Laboratory.
Dr. James A. Van Allen, department of physics, State University of Iowa.
Dr Wernher von Braun, Director, Development Operations Division, Army Ballistic Missile Agency.

The Space Technology Committee also includes Air Force and Navy representatives.

This Committee, according to Dr. Dryden, will "take a fresh look at the research and development problems of space technology and make recommendations as to the needed programs "

Dr. Dryden added that "the major research fields which must find a place in the overall national program include space mechanics; space environment; energy sources; propulsion systems; vehicle configuration and structure; materials, launch, rendezvous, reentry and recovery; communication, navigation, and guidance; space biology, flight simulation; measurement and observation techniques."

NACA Chairman Doolittle told the Senate Appropriations Committee on February 1958 that the NACA is increasingly devoting more time and effort to the problems of outer space. He said: "* * * 4 years ago, about 10 percent of our activities were associated with space; 2 years about 25 percent; and in 1959 we will be devoting almost half of our time on missiles, antimissiles, and satellites and other space objectives "

But Doolittle added that the NACA still has "an obligation to the airplane, not only because of commercial aviation and the fact that our military offensive posture is largely the result of the airplane, but, because there are extensive

new development programs, the completion of which will run into billions of dollars, still using the airplane—the F-108 fighter long-range interceptor; the 110-A, which is the manned bomber to follow behind the B-52, and the nuclear bomber—all of these projects must be carried on."

The NACA basic law

The NACA was patterned after a similar advisory committee established by the British in 1909. In February 1915, a joint resolution creating an American advisory committee was prepared for submission to Congress with the approval of President Wilson.

The resolution was in danger of being lost, however, in the legislative logjam as the March 4 adjournment date neared. Consequently, it was introduced as a rider to the naval appropriations bill.

Following is the provision in the appropriations act, approved March 3, 1915:

"An Advisory Committee for Aeronautics is hereby established, and the President is authorized to appoint not to exceed twelve members, to consist of two members from the War Department, from the office in charge of military aeronautics; two members from the Navy Department, from the office in charge of naval aeronautics; a representative each of the Smithsonian Institution, of the United States Weather Bureau, and of the United States Bureau of Standards; together with not more than five additional persons who shall be acquainted with the needs of aeronautical science, either civil or military, or skilled in aeronautical engineering or its allied sciences; *Provided*, That the members of the Advisory Committee for Aeronautics, as such shall serve without compensation: *Provided further*, That it shall be the duty of the Advisory Committee for Aeronautics to supervise and direct the scientific study of the problems of flight, with a view to their practical solution, and to determine the problems which should be experimentally attacked, and to discuss their solution and the application to practical questions. In the event of a laboratory or laboratories, either in whole or in part, being placed under the direction of the committee, the committee may direct and conduct research and experiment in aeronautics in such laboratory or laboratories: And provided further, That rules and regulations for the conduct of the work of the committee shall be formulated by the committee and approved by the President.

"That the sum of $5,000 a year, or so much thereof as may be necessary, for five years is hereby appropriated, out of any money in the Treasury not otherwise appropriated, to be immediately available, for experimental work and investigations undertaken by the committee, clerical expenses and supplies, and necessary expenses of members of the committee in going to, returning from, and while attending meetings of the committee: *Provided*, That an annual report to the Congress shall be submitted through the President, including an itemized statement of expenditures:"

This language establishing the NACA closely followed that used by the British Prime Minister when he announced the formation of a similar committee to the House of Commons on May 5, 1909, in the following words:

"It is no part of the general duty of the Advisory Committee for Aeronautics either to construct or to invent. Its function is not to initiate but to consider what is initiated elsewhere, and is referred to it by the executive offices of the navy and army construction departments. The problems which are likely to arise in this way for solution are numerous, and it will be the work of the committee to advise on these problems and to seek their solution by the application of both theoretical and experimental methods of research.

"The work desired thus falls into three sections: (1) The scientific study of the problems of flight, with a view to their practical solution. (2) Research and experiment into these subjects in a properly equipped laboratory with a trained staff. (3) The construction and use of dirigibles and aeroplanes, having regard mainly to their employment in war.

"The Advisory Committee are to deal with the first section, and also to determine the problems which the experimental branch should attack, and discuss their solutions and their application to practical questions. The second section represents the work referred to the laboratory (the National Physical Laboratory), while the duties concerned with the third section remain with the Admiralty and the War Office."

On April 2, 1915, President Woodrow Wilson appointed the new Committee.

SIGNIFICANT CHANGES IN THE PRACTICES AND RELATIONSHIPS OF THE NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS AS PROPOSED FOR THE NATIONAL AERONAUTICS AND SPACE AGENCY BY THE ADMINISTRATION BILL (H. R. 11881, H. R. 11882 AND OTHERS)

A section-by-section examination of the administration bill for a National Aeronautics and Space Agency reveals many points of difference in the operations of the proposed Agency from those of NACA. The principal ones are discussed below.

A. The position of the Director

Section 3 of the administration bill provides that the new Agency shall be headed by a Director who shall be appointed by the President by and with the consent of the Senate. This provision has the effect of elevating the position of the Director from his present status as subordinate to the National Advisory Committee for Aeronautics and its Chairman, to that of actual head of the Agency. At present, the Director is not mentioned in the authorizing legislation for NACA; the top controlling body is the National Advisory Committee which is appointed by the President. The Chairman of the Advisory Committee with the approval of the Executive Committee, in turn, appoints the three principal staff officers of the organization—the Director, an Executive Secretary and the Associate Director for Research. At present, no appointment to NACA is subject to senatorial approval. The Director is the head of the present Agency "in all matters except those which by law or regulation require action by the Chairman"—whatever that means, precisely.

B. The National Aeronautics and Space Board

Section 4 of the administration bill establishes a National Aeronautics and Space Board to supplant the present National Advisory Committee for Aeronautics. The size and manner of appointment to the Board are the same as they now are for the Committee. Whereas no more than 8 members of the Board are to be designated from departments and agencies of the Government, with the remainder to be appointed from nongovernmental sources, present legislation for the Committee provides that 10 of the members shall be appointed from specified Government departments and agencies, with the remainder to be appointed from nongovernmental sources.

The functions of the Board as set forth in section 5 of the administration bill appear to accent an advisory role, in contrast to the policy-formulating role which the Advisory Committee now performs. The Director must consult the Board before taking certain actions as indicated, but as the proposed legislation now stands, he would be under no compulsion to accept its recommendations.

C. The designation of the Chairman of the Board

At present the Chairman of the National Advisory Committee for Aeronautics is elected by the Committee by ballot to serve for 1 year Section 4 (b) of the administration bill proposes that the Chairman "shall be designated from time to time" by the President from among the nongovernmental members of the Board only.

D. Functions of the National Aeronautics and Space Agency

The major change is, or course, the incorporation of responsibility for research, both theoretical and operational, into the problems of outer space, in addition to the continuation of aeronautical research.

E. Broader authority of the National Aeronautics and Space Agency

(1) *Authority to hire employees at salaries comparable with private industry.*—Section 6 (b) (2) authorizes the new Agency to hire employees according to civil-service laws but to pay them salaries comparable to those paid by non-Federal employers for similar work. This constitutes an exception to the Classification Act of 1949 and the Federal Employees Pay Act of 1945.

Present legislation authorizes NACA to hire no more than 30 employees at salaries without reference to the Classification Act, and this action is subject to civil-service approval.

(2) *Authority to acquire or construct additional laboratories at the Agency's discretion.*—Section 6 (b) (3) authorizes the NASA to acquire or construct additional laboratories, as well as to take necessary action concerning existing ones, subject to the appropriation of funds by Congress.

At present, NACA may not build additional facilities without prior congressional authorization and specific appropriations.

(3) *Optional compensation for retired commissioned officers.*—Section 6 (b) (10) authorizes the new Agency to employ and compensate retired commissioned officers of the United States and allows such officers a choice as to whether they are to receive the pay of the Agency position or retirement pay.

Officers so employed by NACA have no such option in compensation.

(4) *Authority to detail Armed Forces personnel for service on the same basis as to the Department of Defense.*—Section 6 (b) (11) gives the Agency authority with Presidential approval to enter into cooperative agreements by which members of the Army, Navy, Air Force, and Marine Corps may be detailed to the Agency for service.

Present legislation for NACA is silent on this matter.

(5) *Authority to pay damages for loss incurred as a result of the conduct of the Agency's functions.*—Section 6 (b) (14) authorizes the Agency certain leeway in adjustment of claims for damages for losses incurred as a result of the conduct of the Agency's functions.

Present legislation for NACA is silent on this matter.

F. Power of NASA to transfer to itself related functions

There is no statutory power given to NACA which is comparable to that in section 8 of the administration bill, wherein the National Aeronautics and Space Agency may within a specified time and with Presidential approval and that of the department or agency concerned, transfer to itself functions of such agency which relate primarily to those of the NASA.

G. Appropriations

Section 9 (a) authorizes funds for the new Agency to be appropriated "without fiscal year limitation."

Funds for NACA are "available until expended when specifically provided in the appropriation act."

THE EXTENT OF CONGRESSIONAL CONTROL OVER THE NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS AND THAT WHICH IS PROPOSED FOR THE NATIONAL AERONAUTICS AND SPACE AGENCY

A. Congressional control over basic policy of the National Advisory Committee for Aeronautics

Congressional control over NACA is exercised through the appropriations power. Through this power, control over basic policy can be exercised in several ways.

A cut or increase in the total amount of appropriations for NACA from that which the Agency requests can bring about fundamental revisions in the total research program. The agency may be forced to abandon or seriously curtail certain projects in the event of cut in appropriations. Conversely, additional funds will make possible an expansion of research programs.

The present prohibition in the NACA legislation against carrying over funds except when specifically provided may make it impossible to utilize effectively certain funds, with the result that basic policy may be affected. Section 151e of title 50 on availability of appropriations reads:

"Appropriations made to carry out the purposes of sections 151b–151f of this title shall be available for expenses incident to construction, including administrative overhead, planning and surveys, and shall be available until expended when specifically provided in the appropriation act" (Aug. 8, 1950, ch. 645, sec. 6, 64 Stat. 419).

Section 151b of title 50 authorizes NACA to "acquire additional land for, undertake additional construction at, and purchase and install additional equipment for, existing laboratories and research stations under its direction," but congressional approval and a specific appropriation are necessary if it is desired to construct new or additional laboratories and research stations.

B. Congressional control over basic policy of the proposed National Aeronautics and Space Agency

The proposed legislation for NASA appears to differ with respect to congressional control from that presently exercised over NACA in two important respects. In one respect congressional control appears to be lessened, while in the other it is increased.

The proposed NASA appears to have been given more discretionary power in the use of funds appropriated, as well as a release from the restriction against

carryover of funds. This seems to be apparent in section 9 (a) and (b) which state:

"There are hereby authorized to be appropriated without fiscal year limitation such sums as may be necessary and appropriate for the carrying out of the provisions and purposes of this act.

"Any funds appropriated for the construction of facilities may be used for emergency repairs of existing facilities when such existing facilities are made inoperative by major breakdown, accident, or other circumstances and such repairs are deemed by the Director of the Agency to be of greater urgency than the construction of new facilities."

However, top direction and guidance of NASA which in the case of NACA is solely a prerogative of the President, would for the new Agency be a joint Presidential-senatorial decision. Section 3 of the proposed legislation states:

"* * * The Agency shall be headed by a Director who shall be appointed by the President by and with the advice and consent of the Senate * * *."

The CHAIRMAN. The committee stands adjourned until tomorrow at 10 o'clock.

We will meet in the caucus room tomorrow.

(Whereupon, at 4:55 p. m., the committee was adjourned, to reconvene at 10 a. m., Tuesday, April 29, 1958.)

ASTRONAUTICS AND SPACE EXPLORATION

TUESDAY, APRIL 29, 1958

House of Representatives,
Select Committee on Astronautics,
and Space Exploration,
Washington, D. C.

The committee met at 10 a. m., pursuant to recess, in the caucus room, Old House Office Building, Hon. John W. McCormack (chairman) presiding.

Present: Representatives McCormack, Brooks, Hays, Natcher, Sisk, McDonough, Fulton, Keating, and Ford.

Present Also: George J. Feldman, director and chief counsel.

The Chairman. The committee will please be in order.

We are honored in having as the first witness today Dr. James H. Doolittle, Chairman of the National Advisory Committee for Aeronautics, whom everybody knows is a dedicated American.

We are very glad to have you here before us, Doctor, and you are recognized.

STATEMENT OF DR. JAMES H. DOOLITTLE,[26] CHAIRMAN, NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS, ACCOMPANIED BY HUGH L. DRYDEN, DIRECTOR, AND PAUL G. DEMBLING, LEGAL ADVISER

Dr. Doolittle. Thank you, sir.

I would like, Mr. Chairman, to read a short statement.

The Chairman. You may proceed.

Dr. Doolittle. Mr. Chairman and members of the committee, and counsel:

On April 16 and April 22, Dr. Hugh L. Dryden, Director of the National Advisory Committee for Aeronautics, presented to this

[26] Doolittle, James H(arold), aviator, b. Alameda, Calif, Dec. 14, 1896; s. Frank H. and Rosa C (Shepherd) D.; prep. edn., Nome (Alaska) and Los Angeles (Calif) Junior Coll., 1914-16; A.B., U. of Calif., 1918 (1922); fellow in aeronautical engrng, Mass. Inst. Tech, 1924, M.S., 1924, Sc.D., 1925, m. Josephine E. Daniels, Dec. 24, 1917, children—James H, John P Army aviator, U. S. Army, 1917-30, resigned 1930; maj Reserve Corps. Mgr aviation dept., Shell Petroleum Corp., 1930-40 Apptd. mem. Army Air Corps Investigating Com (Baker Bd.), 1934 Apptd maj U. S Army Air Corps, July 1940, lt colonel to maj. gen., 1942, lt. gen, 1944; commanding Twelfth Air Force in North Africa, Strategic Air Force, 15th and 8th Air Forces, Comdr. 8th Air Force, Okinawa, 1945; on inactive duty since Jan. 5, 1946. Vice pres., dir. Shell Oil Co since 1946, pres Air Force Assn, 1946-47, chairman 1948-49; apptd. chmn of Sec of War's Bd. on Enlisted Men-Officer Relationships; mem. Nat. Adv. Com. for Aeronautics, 1948-50, advisor to Com. on Nat. Security Orgn. and the Joint Congressional Aviation Policy Bd Chairman President's Airport Commission, 1952 Awarded Congressional Medal of Honor, Distinguished Service Medal with one oak leaf cluster. The Silver Star, Distinguished Flying Cross with two oak leaf clusters, Bronze Star, Air Medal with three oak leaf clusters, Bolivian Order of the Condor medal, Yon-Hwei Class III, Grande Officier French Legion d'Honneur, Croix de Guerre with palm, Knight Commander of the Bath, Grand Office of the Order of the Crown with Palm and Croix de Guerre with Palm (both Belgium), 1948, recipient Harmon International Aviation award. Winner Schneider Trophy Race, 1925, awarded Mackay trophy, 1926; Harmon trophy, 1930; winner of Bendix Trophy Race, Burbank, California, to Cleveland, O., 1931 Winner Thompson Trophy Race, 258 68 miles per hr, 1932; also set world's high speed record for landplanes, 1932. Fellow Inst Aeronautical Scis. (pres. 1940), elected hon. fellow, 1950, Royal Aeronautical Soc; mem. Nat. Aeronautical Assn. Contbr. sci. and aeronautical articles Clubs; Army and Navy, Wings. Home 1155 Park Av. Office: Shell Oil Co., 50 W. 50th St., N. Y. City 20.

committee a statement in support of the President's recommendation for establishment of a National Aeronautics and Space Agency. I concur completely with the comments of Dr. Dryden.

Therefore, in the interest of time, I shall limit my prepared remarks to the emphasizing briefly of a number of points, and then attempt to answer such questions as you may wish to ask.

You gentlemen have already spent a tremendous amount of time and energy studying the problems arising from the critical need for our Nation to assert its leadership in the fields of space exploration and space exploitation. You have listened to the testimony of scores of expert witnesses.

One of the most critical of these problems has been whether our national space program should be under military direction or civilian direction or as a joint effort.

My considered answer is that our national space effort must be under civil direction insofar as the very important, nonmilitary aspects of the program are concerned, with the necessary proviso that there must be effective cooperation and coordination between the civil space work and the military space work.

From my years in uniform, I know that the military space projects will benefit greatly from the work of the NASA. It would be difficult, or impossible, for the Nation to fully accomplish its major space objectives if the program were under strictly military control. Direction and leadership of the program must be the responsibility of a civilian agency as provided in the bill.

The President and several Members of Congress have, I believe, clearly reflected the sentiment of our Nation by their proposals that weapons be barred from space by international agreement.

We must, however, have whatever space capability may be required to protect our national welfare.

We must also lead in the peaceful exploration of space, gathering there the vast amounts of new scientific knowledge that may well have the most profound effects upon the future of life on our earth.

I spoke of the essentiality of cooperation and coordination between our military and civilian space workers. Here is where the President's recommendation that the NACA be the nucleus of the NASA is especially important.

For more than 40 years the NACA, while maintaining its independent status and freedom to formulate its own programs, has proved its ability to work most effectively with the military services in pioneering the advances that have made it possible for the United States to maintain leadership in aviation.

A second point I should like to emphasize is the importance of the NASA being organized so that there will be adequate representation of the points of view of all the facets of both government and civil life that are concerned with the national space program. This will be accomplished through the National Aeronautics and Space Board of 17 members.

This committee is not a device that gets involved in the detailed administration of the Agency with consequent delay in time. The NASB, the Board, will serve the Director of the NASA in an advisory capacity.

The Board, as outlined in the bill, would be composed of not more than eight men from the Government with the rest from private life.

Only one Government agency is specifically named, the Department of Defense.

I would expect representation on the Board from the Atomic Energy Commission and the military services, the Army, Navy, and Air Force, to be so obviously desirable as to make unnecessary spelling out this requirement in the legislation.

This would be true also for the National Science Foundation.

Equally sure in my mind, even without legislative stipulation, would be adequate representation on the Board of the National Academy of Sciences through the civilian membership.

The language of the bill is broad. The authorities it contains are necessary to enable the NASA to marshal America's resources as may be needed to carry forward our national space program.

Finally, I should like to stress the importance of planning our national space program to insure that it best satisfies the needs of the United States. As I see it, our projects should be designed to further two goals:

1. The sending into space of highly instrumented vehicles that will send back, or bring back, the new knowledge that our scientists need; and

2. The sending into space of craft that will carry men on their voyages of exploration.

We must learn how to being them back, alive.

In our programing, and in our accomplishments of those programs, we should keep our eyes focused on these objectives. The fact that the Russians may accomplish some specific objectives in their space programs first should not in itself be permitted to divert us from our own designated objectives.

To do what we need to do most certainly will require that we spend substantial amounts of money. It will require that we reach and maintain a high level of effort over a period of many years.

As a nation, we have the scientific competence and the material resources to win our rightful destiny in space. This we must do.

I thank you, Mr. Chairman.

The CHAIRMAN. Mr. Brooks.

Mr. BROOKS. Thank you, Mr. Chairman.

General, I might say parenthetically that I recently had the privilege of seeing some of the original pictures taken on the famous Doolittle raid on Japan—Tokyo. I am impressed by amazing progress which has been made in conquering the air in the few short years that have passed since that raid which you made on Tokyo.

I have been impressed by the stage of the development which indicated such hazards undertaken by our men who made that raid along with you.

Jack Simms has been very instrumental in bringing me up to date on that. I appreciate it.

I want to ask you about the suggestion presented here regarding the new committee, NASA, which would embody the principles and the organization of the NACA.

Of course, I think the organization that you have headed, the National Advisory Committee for Aeronautics, has had a long and distinguished career, too; it has rendered outstanding service.

It is with reluctance that I see it incorporated in another organization.

Will we lose any of the advantages we have gained by doing that?

Dr. DOOLITTLE. No, sir. The new organization, the NASA, not only absorbs the NACA, but it also takes on all of its duties, all of its people, and all of its facilities. So the excellent work that the NACA has been doing in the past will continue to be done under the new organization.

Mr. BROOKS. The merging of one into the other will eliminate, to some extent, the connection which the military has with the NACA.

I notice the reference in your statement, but do you think that is adequate protection for a continuation of the military programs?

Dr. DOOLITTLE. I see no change in relationship between the military services and the NACA as a result of the establishment of the NASA. This relationship has been excellent through the years. I am satisfied it will continue.

Mr. BROOKS. I think it has been excellent, but this new suggestion provides for only one mandatory representative from the military in the new organization.

I notice how you pass by it, that the apparent need would be sufficient to make it mandatory, without writing into the law, that all the services be represented.

Dr. DOOLITTLE. My own feeling is that the Army, Navy, and Air Force should be represented. I am satisfied they will be whether it is written into the law, or not.

Mr. BROOKS. If it is written into the law, then there should be three spaces for the military?

Dr. DOOLITTLE. Four spaces, sir.

Mr. BROOKS. Defense, Army, Navy, and Air Force; is that it?

Dr. DOOLITTLE. That would be my recommendation. If my opinion were asked who to have on as the 8 members from the Government, I would say that 4 of those spaces should be for the Department of Defense; that would be a Department of Defense representative and a uniformed representative from the Army, Navy, and Air Force.

The CHAIRMAN. Are they on there now?

Dr. DOOLITTLE. At the present time, sir, there are 2 representatives in uniform from the Navy; 2 from the Air Force, and there is legislation pending to put 2 on from the Army. That legislation would increase the number of members of the board from 17 to 19.

The CHAIRMAN. That is not the Advisory Board, now?

Dr. DOOLITTLE. The Army representatives are on the subcommittees, but not on the main board.

There are 2 military members from the Air Force, and 2 from the Navy, plus 1 from the Department of Defense. So we presently have five members from the Military Establishment.

Eventually we would have 7, increasing the total number of board members to 19 had that legislation passed.

However, this proposal is holding up the legislation.

Mr. BROOKS. Then you would have the same relative situation if you allowed one representative from each one?

Dr. DOOLITTLE. I think one is adequate.

Mr. BROOKS. Which would make a total of 4 out of 7?

Dr. DOOLITTLE. Which would make a total of four, and this to me is optimum.

Mr. BROOKS. I think this is extremely important, certainly at the inception of the board that there be adequate representation from the military because the military has carried on the programs.

If by chance, and I do not expect this to happen, the board would be set up with a minimum representation from the military, which would be one under this bill, you might have a break in the military programs that have been carrying on in the past and not a continuity. That is true, is it not, General?

Dr. DOOLITTLE. Yes, that is possible.

Mr. BROOKS. In case we cannot get one representative from each service, plus the Defense Department, would you suggest as a preliminary matter for the first year or two that we have that number and after that make it optional?

Dr. DOOLITTLE. We certainly should start off with this new organization, with four people from the military.

However, the legislation is written in such a way to permit great flexibility and will permit it to change with the times as required.

Mr. BROOKS. A Reserve officer would not be military; he would be civilian, would he not?

Dr. DOOLITTLE. At the present time the representative to the NASA from the Defense Department is a civilian. The four representatives, 2 from the Navy, 2 from the Air Force, are senior Regular officers.

Mr. BROOKS. Would you consider yourself, for instance, a civilian or military, or both?

Dr. DOOLITTLE. I resigned from the Military Establishment in 1946. I did not retire; I resigned, so I am 100 percent civilian.

Mr. BROOKS. You are a civilian, that is the way I analyzed it.

I think it is extremely important that we move as quickly as we can to some sort of international agreement. How would you work that, though, General?

Dr. DOOLITTLE. International agreement?

Mr. BROOKS. Yes. You refer to that on page 2 of your statement. You say:

> The President and several Members of Congress have, I believe, clearly reflected the sentiment of our Nation by their proposals that weapons be barred from space by international agreement.

Have you thought of any procedure that you would use? Would you, for instance, go to the United Nations, or would you go to later called conferences? Would you go to the summit? What have you in mind?

Dr. DOOLITTLE. As an ex-military man, a technical man, and a businessman, with little or no knowledge of politics and diplomacy, I would say that question should far better be answered by someone more knowledgeable on the subject than I.

Mr. BROOKS. Regardless of the method used, you feel it is very important we have an agreement at an early date?

Dr. DOOLITTLE. Yes, sir.

Mr. BROOKS. The agreement, you indicate, should not be such as to prevent us from adequately defending our own country if that can be done?

Dr. DOOLITTLE. Mr. Brooks, I believe you bring up a question of international control of space.

Mr. BROOKS. That is right.

Dr. DOOLITTLE. This is a very difficult question indeed. Certainly we can take certain landmarks and we can say that we would not want enemy aircraft or spacecraft directly over the United States in a posi-

tion from which they could attack or not, but still in a position from which they could attack.

On the other hand, it is quite impossible to say that we own space out to infinity because it is over us because as our earth rotates we would sweep the entire heavens and you could not say who owned space.

But at some point certainly we should be able to shoot down any enemy craft that comes overhead.

Above that point, space, in my mind, should be international.

Now, where that point is, it is difficult to say. A few years ago it would have been impossible for us to shoot down anything over 50,000 feet. Now we can shoot down something comfortably at 100,000 feet, or 20 miles.

At some future date we should be able to shoot down potential military weapons at much higher altitudes, but for certainty at some altitude the space should be free and, I hope, there will come a time when at all altitudes will be free for peaceful purposes.

Mr. BROOKS. The altitude that you would specify would probably be an altitude that would be high enough to protect this country.

Dr. DOOLITTLE. That is right, as long as the threat of war exists.

Mr. BROOKS. That might vary from time to time as instruments are perfected?

Dr. DOOLITTLE. That is correct. You would expect that altitude to increase.

There, again, I could give only technical advice, not legal advice on this question, and it is an extremely complicated legal question.

The CHAIRMAN. I think you gave a very fine answer as far as I am concerned.

Mr. BROOKS. I think so, too. You have given an excellent answer there.

The CHAIRMAN. You have given the best answer I heard during these hearings.

Dr. DOOLITTLE. Thank you.

Mr. BROOKS. The doctrine of civil law is that a man owned just as far down as there was earth and as far up as there was any space over his property. That doctrine of civil law will be changed, however.

Dr. DOOLITTLE. Yes, sir; because you can only go 4,000 miles down until you come to the center of the earth, but you can go out a real far piece before you come to the edge.

Mr. BROOKS. I grant you that.

I want to ask you this question while you are here, General. We do not have an opportunity to hear or see you often, sir. Are you satisfied with the progress that is being made in the exploration and our scientific development of space?

Dr. DOOLITTLE. No, sir. I feel that this bill would permit a coordination of our efforts and would encourage greater effort, would encourage greater expenditures and would result in more rapid progress.

Mr. BROOKS. Wherein do you think we have fallen down in the past?

Dr. DOOLITTLE. In the past I do not believe the people of the United States, as a whole, have had an appreciation of the importance of space because it seemed as remote as Buck Rogers.

More recently, as a matter of fact, last October, we came to a sudden realization of the importance of space because somebody had gotten there before we did. Now, with a public awareness, I do not believe we have yet caught up with what it is possible to do with a well organized and coordinated effort. This is in progress at the present time.

I think we are in the process of catching up. But your question, I believe, was: Was I satisfied with where we are. No.

Mr. BROOKS. This will help us catch up?

DR. DOOLITTLE. Yes, sir.

Mr. BROOKS. How much money do you think we should spend yearly on the program?

Dr. DOOLITTLE. The amount of money we spend on this program is a compromise amount and I believe that we have to take into consideration our overall national income, our overall national budget, and many of the other things that are of interest to the people of the United States.

The CHAIRMAN. Including the necessities?

Dr. DOOLITTLE. Yes, sir.

Even under those conditions I feel that we should promptly increase our space budget. I believe Dr. Dryden has told you that the thinking was that the NASA in the first year would probably double the NACA expenditures.

In the next 4 years or 3 years, thereafter, it would quadruple it.

So we think of going from the present $100 million a year to $200 million a year, to $400 million a year. This permits an orderly program which Dr. Dryden and his people in collaboration with the military, are now endeavoring to work out.

Mr. BROOKS. That would be a 3-year program and up to $400 million?

Dr. DOOLITTLE. Yes.

Mr. BROOKS. That would not be a program of actually developing these spacecraft, would it?

Dr. DOOLITTLE. It would include the development of space craft. That is one of the new obligations.

In the past the NACA dealt primarily with planning and with research in flight. It was called an advisory committee, but almost from its inception that was a misnomer.

The new NASA will have those obligations and in addition is directed to develop a comprehensive program for civilian space flight and to develop tests and operate vehicles.

Also, they will have to contract on a much larger scale.

So we would expect that that extra money would be spent in those new obligations.

Mr. BROOKS. Now, your $400 million surely would not include the missile program, would it?

Dr. DOOLITTLE. No, sir.

Mr. BROOKS. Ballistic missiles and all of that would be different?

Dr. DOOLITTLE. The missiles program is strictly a military program. The reconnaissance satellite is strictly a military program.

Part of the program is strictly military; part of it is strictly scientific. Part of it is strictly research.

There is a fuzzy area in the middle that will have to be resolved, which is in the process of being resolved.

Mr. BROOKS. For what would you expend $400 million?

Dr. DOOLITTLE. That would be scientific, development, test, exploration, all of the civil space activities that are not directly related to the military.

Mr. BROOKS. All pure science would be included?

Dr. DOOLITTLE. Pure science would only be part of it.

Mr. BROOKS. General Doolittle, because you are so well known, the people of the country have so much confidence in you, I would like to have you tell this committee, how far you think the Russians are ahead of us in the development of the missile and the satellite program, if you think they are ahead, and in addition to what you have already said, what might we do to overtake and pass them?

Dr. DOOLITTLE. At the present time the Russians have put a much larger satellite in the air than we. They obviously have the first third of the ballistic missile further along than we have. That is the propulsion part.

The problem in ballistic missiles is in three basic parts: First, propulsion, the ability to shoot it where you want it.

Second, the guidance, the ability to direct it exactly where you want it to go.

And, third, the reentry.

We know the Russians are ahead of us in the first third of it. We do not know exactly where they stand on guidance and exactly where they stand on reentry.

We do know where we are. I would say that the Russians are ahead of us in the ballistic missile program therefore, and that it will require our very best efforts to catch up.

I believe those efforts are being expended. The present ballistic missile program is going ahead in very good shape.

As far as the satellite program is concerned, the Russians have put a much larger satellite in the air than we.

It will be some time before we will be able to put a satellite in the air as large as that of the Russians.

So I would say the Russians also are ahead of us in the satellite program insofar as their abilities to put a large satellite in the air is concerned.

On the instrumentation of the satellite, I do not believe they are ahead of us. I believe we have just as good scientific instrumentation as they.

However, Dr. Dryden can answer that question more intelligently than I.

Mr. BROOKS. Because the American people know you so well, I want to ask you one more question, and then I shall have concluded.

Since you feel the Russians are ahead of us in this respect, do you think that this fact that they are ahead of us in this development constitutes a definite threat to our security, our safety as a people, until we overtake them?

Dr. DOOLITTLE. I would rather, Mr. Brooks, put that on a somewhat broader scale, and say that the Russians have an arms and ammunition economy. They are working very hard and on those things to which they have directed themselves, they have been able to progress more rapidly than we. It is going to take our best efforts to keep ahead of Russia in those things that will keep us out of war and in those things which we as a nation require.

I feel that the solution of that is not merely the development of a space program. I think the development of a space program is an important part of it, but I feel that we in America have to become aware of the situation.

We must know more about international conditions. We must be willing to work harder and if necessary we must make some sacrifices.

Mr. BROOKS. Just one final question. I notice in the press in the southwest part of the country that rocket scientist Frederick G. Saumer said the other night in a speech down there that the Russians had taken 16 shots at the moon.

Where he got his information from, I don't know. Do we have any intelligence that you know of that they have been firing at the moon and missed the moon?

Dr. DOOLITTLE. I know of no such intelligence, Mr. Brooks; however, it is quite possible they could take a shot at the moon without our knowing about it.

However, you will remember that in my statement I said that we must have a comprehensive program of space research, space technology, and space exploration. And simply because the Russians are first in some particular phase of this should not necessarily cause us to change our program.

If they got badly ahead of us in an important phase, then it might be necessary for us to change. But I would say a shot at the moon by the Russians would not be sufficient to cause us to change a sound program.

Mr. BROOKS. We could not take a shot at it ourselves without the Russians knowing about it; could we?

Dr. DOOLITTLE. It is very difficult for us to do anything without the Russians knowing about it.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. When Dr. Dryden appeared before our committee, he pointed out the fact that the NACA is an operating agency and not an advisory agency.

This particular bill or a bill similar to this before the committee would also provide that the new agency would be an operating committee.

How long have you served as Chairman of the Board of the NACA, General?

Dr. DOOLITTLE. I have been Chairman of the Board for something over a year and a half.

Mr. NATCHER. The Board of NACA has 17 members at the present time?

Dr. DOOLITTLE. Yes, sir.

Mr. NATCHER. The provision in our bill, also, as you well know, calls for 17 members. Since you have served as Chairman, do you find that this size board is too large? Should this number be reduced from the standpoint of efficiency and having a good operating agency?

Dr. DOOLITTLE. I would like to answer that question, sir, by saying that the smallest board that will give adeouate representation to all of the Government and civil agencies involved is the most desirable board.

I believe that the number 17 accomplishes this purpose very well indeed. I would not recommend that it be increased even though some of the present governmental members will have to be removed,

if we go along with the idea of putting 4 military people on it, because that leaves only 4 spaces for other Government agencies.

Certainly the AEC should be on it. Certainly the National Science Foundation should be on it. Then there are only two spaces left. Certainly the Civil Aeronautics Authority should be on it. Then there is only one space left.

Then you begin to wonder what to do with that one space and possibly the Weather Bureau should have it because the Weather Bureau deals with the environment in which we operate certainly until we get out of the earth's atmosphere. So that is all of your eight spaces used.

Now, you have taken off the Undersecretary of Commerce who is presently on it. You have taken off the Secretary of the Smithsonian who is presently on it, and you have taken off the Director of the National Bureau of Standards who is presently on it.

So you say right away you would like to have three more spaces, but to have three more spaces you would, I think, get an unwieldy board.

Seventeen is a number with which we have dealt very successfully, and it seems to me the minimum that will permit us to have all of the representative disciplines and governmental agencies with whom we deal involved.

We meet once a month, on special call if necessary in addition to that, and we are able then to discuss with the Director his problems and there is somebody there who represents each one of the agencies outside of the NACA with whom he is obliged to deal

This has proved to be a very great help to the Director. However, perhaps I should not say that as Chairman. I think the Director would say it, however.

Mr. NATCHER. Another provision to this bill, General, provides that the Board shall meet at least four times each year. I believe the NACA organization has the same provision.

Dr. DOOLITTLE. It is the policy of the NACA to meet once a month with the exception of occasionally skipping a month in the heat of the summer and sometimes the Christmas month, if there are no particularly important things to act on.

However, they also meet for several days at the laboratories from time to time, if there are special jobs to do. My own feeling is that the Committee should continue to meet on an average of once a month, and to be ready to be called if the Director has a special problem that he would like to discuss with them.

Mr. NATCHER. General, as you know the bill presently provides that a director shall be appointed by the President and confirmed by the Senate. Considering your experience as Chairman of the Board of the NACA, what type of individual should be the Chairman of the new space committee? Should he be a scientist? Should he be a man from industry? What type of individual, in your opinion, General, should the new Director be.

Dr. DOOLITTLE. In my mind the new Director should, first of all, have an open mind. He should be a man who can accept and deal with new concepts. Next, he should be a technical or scientific man.

He should know technology or science. Better yet, technology and science. Next, he has to be an excellent administrator. Last of all, he has to be a good salesman because he is obliged to get the money, the facilities, the things that he needs to do his job.

Therefore, he has to be able to present his programs in a way that will make it possible for him to realize them.

Mr. NATCHER. General, if we declassified some of our materials, could we move forward a little faster?

Dr. DOOLITTLE. Would you repeat the question, sir?

Mr. NATCHER. The declassification of some of our materials. At the present time, how do you feel about declassification? We have had witnesses before this committee that definitely were of the opinion that we should declassify some of our material at this time.

Do you believe that could be done and it would help this program and other programs in the missile and outer space program that we are now in at the present time?

Dr. DOOLITTLE. In a general way, yes, sir; I feel there should be additional declassification. But whenever we deal with the military services and the work that we do has direct or indirect military application, I feel that that declassification or lack of declassification should come through the military.

The CHAIRMAN. You mean the military should have the control over the question of declassification?

Dr. DOOLITTLE. I mean wherever we do work specifically for the military, I feel the military should say whether or not it should be declassified, and not the NACA.

Dr. DRYDEN. May I inject, Mr. Chairman, that the NACA does have power to classify material originating in its own projects, if it seems desirable. We do classify documents and have a very active declassification program.

The average life of a classification is something like 3 years. General Doolittle is referring to work that we do specifically for the military. We work on the 110–A bomber. The declassification of that work comes through the military.

Mr. NATCHER. General, the NACA is quite an organization. I believe the organization controls and operates between four and five hundred million dollars worth of property and has 7,600 employees, approximately 4,000 of them scientists or men and women with the approximate qualifications of a scientist.

Now, General, since you have served and are serving as Chairman of the NACA, you know of the many hardships that have confronted your particular agency. Would you point out to this committee what the main obstacle is that has confronted your organization in the operation of this particular program since you have been Chairman.

Dr. DOOLITTLE. The Congress has been very kind in permitting us to have the money we require for new facilities. I would say that the fine work done by the NACA is largely the result of the excellence of its people. I would say that our greatest problem is the acquisition and retention of competent people.

Mr. NATCHER. General, thank you very much. I want to thank you for your fine statement and for your testimony before this committee at this time.

Dr. DOOLITTLE. Thank you, sir.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. General Doolittle, in view of your answer to Mr. Natcher's last question, I would like to discuss with you, on specific terms, your reason for advocating the new legislation which we have before us.

What primarily do you consider to be of paramount importance in the new legislation of the new Space Committee that is proposed to be set up under this legislation? What are the prime requisites over and above what NACA is doing at the present time?

Dr. DOOLITTLE. Did I understand you to say what are the prime things that the NACA has to have that it does not have now?

Mr. SISK. That is correct.

Dr. DOOLITTLE. Contract authority to contract with outside agencies. We presently have a very small authority and ability to contract. We do very little outside contracting.

This will have to be substantially augmented and is outlined in the bill. The other problem with which we will be faced, if a substantial part, let us say eventually half, of our work is done in governmental laboratories and half by contract laboratories outside of Government, is some way of equating pay between the people in the governmental laboratories and in the contract laboratories. That is covered by the bill.

Mr. SISK. Of course the thing that many of us have been concerned about is the actual need for a new agency that would really expedite and help to move ahead in the field which we are, of course, all concerned with.

It is my understanding that the NACA is at the present time doing substantial work in space research, which, of course, would be part of the new agency. You are doing some contract work. Do I understand that, legislatively, you are to closely limited with reference to contract authority under the present NACA, General?

Dr. DOOLITTLE. I will let Dr. Dryden answer that.

Dr. DRYDEN. At present we have contract authority to contract on special investigations with a limitation of $500,000 a year. This is the present contracting authority for research.

We, of course, do contract for construction, for equipment, in the usual sense. If I might supplement General Doolittle's answer, the two very new things are the authority to operate space vehicles, to acquire and operate these vehicles. The other is to undertake what we speak of as hardware development.

At the present time the NACA does not undertake the development of airplanes or missiles or engines. This law provides the authority to develop space vehicles.

Mr. SISK. That is the point I was attempting to pin down here, to try to determine exactly what, in addition to the present authority of NACA, is needed. It was my understanding that General Doolittle felt that the NACA should be the nucleus of the new organization and he mentioned that it would have, to some extent, the same group of people, and so on.

I think that becomes rather important because some of us have had some concern about what we needed to do, and whether or not we needed a tighter type of authority, for instance something along the line of a commission similar to the Atomic Energy Commission, rather than a large committee. That is why I was asking for specifics as to the reason why you were supporting the new legislation.

Dr. DOOLITTLE. I am satisfied that the NASA can take on its additional obligations with the changes that I suggested. You will observe that in the changes suggested that the Director is given

additional authority. He becomes the chief executive, so there is one chap responsible.

Mr. SISK. That, as I see it, General, is actually the greatest and the main change in the new legislation, the new position of Director which, as I understand, is entirely different from the method by which NACA proceeds. This Director would have susbtanial authority and would be able actually to operate, based on his own decisions, and the Board would only have authority to recommend or to advise. Is that in your understanding?

Dr. DOOLITTLE. That is my understanding and that is the way I believe the most rapid progress can be made in this field, by having straight-line responsibility and authority.

Mr. SISK. You would visualize, then, that the Director, with the power which he would have under this legislation, would report directly to the President. Is that right?

Dr. DOOLITTLE. The President might put, as an intermediary, his assistant for science and technology in; otherise he would report directly to the President.

Mr. SISK. I might say along this line, General, that this is a question which has been asked of almost every witness who has been before us, and that has to do with whether or not you feel that science and technology should have a place in the Cabinet today, whether or not we should have a Secretary of Science or Department of Science, or Department of Space Technology at the Cabinet level.

Dr. DOOLITTLE. I do not want my answer to seem facetious, but my feeling is very strong that we should do nothing to complicate our present system of Government unless there is a real reason for it, and I do not see a reason for this.

Mr. SISK. I can appreciate that it already is too complicated in many areas, General. I will agree with you on that.

The point, of course, in the minds of some is that we should place emphasis upon the feeling that maybe some years in the past we have not properly emphasized scientific and engineering know-how and development research and so forth.

Dr. DOOLITTLE. I agree entirely. In the past science and technology has not had a voice in the highest levels of Government. However, now, Dr. Killian sits in the meetings of the National Security Council.

He sits in all of those Cabinet meetings that deal with scientific or technological matters. He sits on other committees. He is the director-adviser on scientific and technical matters to the President.

So I believe that science now for the first time does have a voice in the highest levels of our Government; that is, the executive side of our Government, sir.

Mr. SISK. General, do you feel strongly about the possible failures in our educational system at the present time?

That, also, is the subject, as you know, that is receiving quite a lot of discussion now. There are certain criticisms of our educational system with reference to proper emphasis on mathematics, on science, and subjects of that kind.

Do you have any particularly strong feeling on that issue?

Dr. DOOLITTLE. Yes, sir. I feel very strongly on that subject and I go back to my original contention that the reason that the Russians

are picking up on us in some areas is because in those areas they are working harder than we are, not because they are any smarter.

In school they are working harder than we are. Even at the elementary-school level the students are working harder than ours. I feel that in elementary school we should start the youngsters working harder, and that they should learn some discipline, more than they are presently learning in the elementary schools.

In the secondary schools I believe we should have more classrooms, more teachers, better teachers, particularly better science teachers, so that those students who wish to study science can.

In the colleges I believe we should have professionals turned out who are not only good lawyers, good engineers, good doctors, but also who are good American citizens.

For that reason, I feel they should have some of the humanities. By the humanities I do not mean Latin and Greek, but learning something of history, of geography, of government, of other peoples of the world, and how they live.

I feel that our educational system needs an overhaul from top to bottom.

Mr. SISK. General, I am inclined to agree with everything you have said, but let me ask you this further question without any attempt to put you on the spot. Do you have any recommendation that you could make to this committee or to any other committee of the Congress as to what might be done to correct that situation?

Dr. DOOLITTLE. I would like to see the Federal Government take the lead in improving our school system and I believe one of the things they can do is to appropriate more money for that purpose.

Mr. SISK. Do you feel that the lack of proper pay or salaries for our teachers all the way from the primary grades clear through to the universities has been a detriment?

For example, industry can pay a top scientific man, who might be an excellent teacher in a university, 2 or 3 times what the university can. Do you feel that has any influence?

Dr. DOOLITTLE. I would like to answer that in part in connection with a question you asked earlier about the Russians. I would not suggest that we follow the Russians except in our ability to work a little harder than we are working.

But the Russians have done two things which we have not done in their school system. First, they have given an incentive to the teacher to remain with teaching. For instance, a top scientist teacher in Russia gets 50 times as much as a laborer. Here, some teachers do not get as much as a laborer.

This, I feel, is basically wrong. It is a fault in our system that we should correct. The other thing is that in Russia premium is put on intellectual capability as well as athletic capability. So the youngster, when he gets to the top as a good student, is given prestige commensurate with his intellectual capacity.

Here, we are inclined to give to my mind too much credit to the athletic prowess of a student and too little to his intellectual capability.

Mr. SISK. Thank you, General. That is all, Mr. Chairman.

The CHAIRMAN. Mr. Fulton.

Mr. FULTON. General, we are very glad to have you here because we Americans look to you as a very distinguished American and one who has contributed much to our country.

You have read the comments now and have read the legislation about the need for a new space program. In your considered judgment, is a new Space Agency necessary, to be set up by the Federal Government and recommended by this committee to the Congress. Must we have a new Agency?

Dr. DOOLITTLE. I believe that this is the best way to accomplish our agreed purpose, and that is to get on faster with space science and space exploration.

Mr. FULTON. That means that the present facilities, while they are adequate for the current programs and have made wonderful progress, are not adequate for the expanded national space program that this committee is developing?

Dr. DOOLITTLE. The present facilities of the NACA are presently being utilized in part for work directly or indirectly related with space activity. But in the new organization these facilities would continue to be expanded and augmented gradually, but the new organization would also take on contractual authority to run other laboratories and this it does not yet have, and this is an important part of the overall.

Also, the job of the new agency, which is not being done, or could not be done with the present charter of the NACA, is to develop a comprehensive program for all civilian space activities.

Mr. FULTON. That brings up the question as to the extent of the authority of the proposed new National Space Agency. Should it be both a research and development agency as well as an operational agency?

Dr. DOOLITTLE. Yes, sir.

Mr. FULTON. Would you have this new Space Agency continue the maintenance of laboratories, the manufacture of particular space vehicles, and hardware for the purpose of a space program?

Dr. DOOLITTLE. I would have it maintain laboratories for research, some development. I would have all manufacturing done by industry.

Mr. FULTON. In the bill which the chairman of the committee, Mr. McCormack of Massachusetts, has sponsored on behalf of the administration, there is the name of the new proposed Agency set out on page 3, the National Aeronautics and Space Agency. May I just comment on that name.

The name as proposed is a mixture to me on the one hand of both a method of navigation, aeronautics, and on the other hand, a place, so that the two adjectives are not the same type.

I would like to see the Agency called the National Space Agency or else the National Space Agency for Research, Development, and Exploration, or, if we consider the method of navigation, we would call it the National Aeronautics and Astronautics Agency, or if we talk only of the place alone, then we would call it the National Air and Space Agency.

But we should not confuse the method of navigation with the place where the operation is to occur. Do you agree?

Dr. DOOLITTLE. Mr. Fulton, I do not think the name of this organization is particularly important. I do feel that the NACA has come to have a connotation in the minds of industry and governmental people associated with aviation.

Many of these same people are going ahead right out of the air and into space. The NASA is only a slight change in name and probably would have the advantage of continuing to remind them of the excellent past in the history and the tradition of the NACA.

But whether it is called the National Aeronautics and Astronautics Agency, or whether it is called the National Aeronautics and Space Agency to me is not a particularly important thing.

Mr. FULTON. But to the public and to the world it will be the question of whether we are simply continuing the NACA, the National Advisory Committee for Aeronautics, under a slightly expanded form or whether we are starting out on an entirely new broadened program with the aeronautics purposes as simply a part.

Does that have any bearing on your thinking?

Dr. DOOLITTLE. Mr. Fulton, two things have been done that I think are important in this new title. One is to get rid of the word "advisory" which is a misnomer, and the other is to put in the word "space" which, to me, overcomes the problem that disturbs you; and that is, it means we are not now strictly dealing with aeronautics but have gotten out into astronautics.

I am perfectly satisfied with the name. I would be perfectly satisfied with the change in name, and I feel that the results of this new Agency will soon prove it.

Mr. FULTON. We on this committee, I am sure, want to recommend the establishment of a space agency that will have a broad field of activity, and not be bound by possible previous limitations.

When the administration first sent up the Marshall plan it was called the military aid program. It was my amendment, I am very glad to say, that turned it into the mutual defense assistance program, putting the word "mutual" into it.

That word "mutual" I have heard used many times in speeches, but it means mutuality in defense and assistance. The question on this is; should we just simply expand the name a little of the present NACA and expand the functions of NACA a little or should we put this National Space Agency into an entirely new frame of operation, an entirely broadened field, and with a tremendously accelerated program? Which do you recommend?

Dr. DOOLITTLE. I recommend the present bill. I recommend an accelerated program that is a well-coordinated and well-thought-out program. I do not believe that it is desirable to go into a tremendously accelerated program until we know just where we are going, it is a problem of semantics here.

Mr. FULTON. It is largely a degree of magnitude whether simply to increase and accelerate current programs or to embark immediately on the research and development and basic scientific study; for example, in the field of the ion engine, photon propulsion, the solar energy propulsion, the development of the one-third of a million pound thrust engine, the million-pound thrust engine, the million and a half pound thrust engine, the development immediately of a program for a manned space ship, for exploration of outer space, or of the moon, the development of programs that will look into the chemical radical changes that will permit us to use the upper level of oxygen, for example, for space vehicles at a 60-mile level.

If we look at the program in that relationship it is a tremendously expanded program in addition to the ordinary improvement of the useful performance and safety of airplanes.

Dr. DOOLITTLE. I believe all of the programs you have suggested should be explored; that money should be spent on those according to their likelihood of prompt realization.

I do not believe that we should go, for instance, into an extensive development of the ion propulsion system at this time. I believe we should continue to do research on it and get as much information as we can and we should even do some development.

You know much more about the ion system than I do, but to me it is something that will be extremely useful but at great distance and over long periods of time.

The first job that the NASA has been asked to do is to outline a program. This comprehensive program can be a program that will take a great many billions of dollars per year or it can be a program that will grow gradually to whatever science indicates are useful things to exploit. That is the program I would like, the latter one; that is, an accelerated program, but not a crash program.

Mr. FULTON. Dr. Van Allen had recommended a program to begin with in the magnitude of a half billion dollars a year to start. Is that larger than you are thinking of personally?

Dr. DOOLITTLE. If we were given a half billion dollars and told to spend it effectively, it would be very difficult to spend that in the first year. We could probably allocate it in the first year and spend it over a period of time.

Mr. FULTON. But with a good practical vision you could make plans if you knew you were going to get, under NACA expanded to NASA, sums of money that would permit you to develop at the rate of a half billion dollars as you moved into that level?

Dr. DOOLITTLE. That is correct, and I would certainly want to start the one-third of a million pound rocket study at once.

I certainly would want to study the million-pound rocket study at once. I would delay the million and a half pound a little to see how the others were going but phase it in as required.

Mr. FULTON. As a matter of fact, the lifting of weight has in and of itself no particular practical gain at the present time since advanced instrumentation, guidance, and engines are not prepared.

Dr. DOOLITTLE. The program must go forward on a company front. It is not desirable to work on one thing and get way out ahead so that the things that support it are way behind. That is why we must have a coordinated program.

Mr. FULTON. On the million-pound-thrust engine, so far Congress has given money at the rate of about $500,000 annually. Is that not correct, Dr. Dryden?

Dr. DRYDEN. That is the present expenditure for study.

Mr. FULTON. On the million pound thrust engine it would probably run, as an educated guess, maybe $200 million to complete a project of that type.

At the present rate of study and expenditure by Congress it would take us 400 years to come to a million pound thrust engine.

Would you recommend that our program and our basic study on the million pound thrust engine be greatly expanded? For example, should $15 million or $25 million be allocated so that the planning study be done, not expended all at once?

Dr. DOOLITTLE. I would see this as an exponential curve by which at the present time we are spending a little money, which is all that is required to make the study and learn more. As you learn more you can spend more money.

It would not be $500,000 a year for 200 years. It would be an increasing amount until at the end of 5 years you would have your project completed.

Mr. FULTON. You would then plan for the expenditure of maybe $150 million to $200 million for the million pound thrust engine for the next 5 years?

Dr. DOOLITTLE. If that is the time that the technical people say it will take to produce that.

Mr. FULTON. You have spoken of a civilian agency to exercise and implement, both on the research and development and operating basis, the national space policy.

Why not have that Space Agency have the full jurisdiction of all space activities, including both civilian and military?

Dr. DOOLITTLE. I believe the military have specific problems that are characteristic of the military and that they must control in order to do their job. One of those is immediately the missile program, the intermediate range and the intercontinental missile.

Those are strictly military and I believe they should be under the military. Another is the reconnaissance satellite.

Now, when you come to the weather satellite or satellite used in communications, then there is a fuzzy area whether they are military and civilian because both the military and civilian benefit from it.

As I said when I started, to me there are some things that are strictly civil. They should be done by a civil agency because the military would have less interest in them than they would in strictly military things.

However, the things that are strictly military should be done by the military or the agency which required them. In the middle there is a fuzzy area which has yet to be resolved.

Mr. FULTON. Do you agree with Dr. von Braun that we should proceed immediately with a program to launch a missile to propel a man 150 miles into space? Is that worthwhile and practical to you?

Dr. DOOLITTLE. I believe that program should be evaluated along with all of the other programs, and see whether it fits in as a useful part of a comprehensive plan.

Mr. FULTON. With reference to the manned vehicles that will enter outer space shortly it is a problem of both astronautics, guided missiles, as well as short-time space.

That brings up this question: Should that be completely military, or should we say, "Look, we are going to look ahead to the time when we will transport passengers between New York and London in one-half hour or we are going to be able to get these vehicles in the air as freight carriers for civilian purposes."

Dr. DOOLITTLE. I do not believe that the development of space travel should be strictly military. Certainly it has a military application. This is one of the things in the area that might well be a joint operation.

Mr. FULTON. Then why not give one civilian agency such as the National Space Agency the control of the policy and then put in that Agency the operations on a civilian basis, and put in the military, the Department of Defense, the operations on a military basis with some sort of liaison military committee to work out as they progress the fuzzy or the jurisdictional areas where they might overlap?

Dr. DOOLITTLE. I believe that at the present time that is substantially what is done with ARPA handling the military part, and with the thought being that the NASA would handle the civilian part.

Mr. FULTON. You do now have a jurisdictional committee operating with ARPA, do you not, to decide between NASA, CAA and ARPA, settling the questions regarding operations and research and development field?

Dr. DOOLITTLE. That is correct.

Mr. FULTON. Let me read the provisions of the statute of the proposed bill:

> The Congress further declares that such activities should be directed by a civilian agency exercising control over aeronautical and space research sponsored by the United States * * *

I am reading on page 2. The provision then goes further and says, and I refer your attention specifically to this provision:

> * * * except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations, in which case the agency may act in cooperation with, or on behalf of, the Department of Defense.

The words that are of particular significance are,

> may be peculiar to, or primarily associated with, weapons systems or military operations.

In your opinion, will that language limit too closely and be too severe on an agency like ARPA in the Department of Defense so that it will not be able to have a broad enough field to conduct basic research and continue a good many of the basic research programs that are already operating under it?

Dr. DOOLITTLE. The interpretation of that particular phrase will be the determinant. I believe the military services do need to do some research or have some research done for them. They must have the results of basic research.

Mr. FULTON. Because this language is indefinite and Dr. York has interpreted it one way and others have interpreted it more broadly, and with the fears that there might be some restriction in this language, would you at this point in the record and at your leisure submit a form of language that is nontechnical that will outline the necessity of keeping basic research in ARPA?

I want to make sure it is kept, so could you give us something that, in your opinion, will settle the trouble and indefiniteness of this language?

Dr. DOOLITTLE. You want me to write that and send it to you?

Mr. FULTON. If you will, for the record.

Dr. DOOLITTLE. Yes, sir.

Mr. FULTON. That is all. Thank you.

(The information above referred to is filed with the committee.)

The CHAIRMAN. Gentlemen, I will have to leave shortly because of my duties as majority leader.

So with the permission of the other members I will ask you a few questions at this time.

Mr. Fulton called your attention to page 2:

> The Congress further declares that such activity should be directed by a civilian agency.

"Should" is a sort of cloudy word, a word of qualification. Should that not be "shall"?

Dr. DOOLITTLE. I believe that is the intention.

The CHAIRMAN. Now, on line 7, it says: "except". Now when you get to the word "except", that is a pretty broad word. It is a sharp word—"in so far as such activity may be peculiar to, or primarily associated with, weapons systems", and so forth.

I thoroughly recognize the importance of the military and I am for it very strongly in the world of today. But with language like that, if the military says that any activity falls into the intent of the word "except", and is primarily peculiar to or primarily associated with the military, and on the other hand, the new Space Agency takes a contrary view, then under this language would not the position of the military prevail?

Dr. DOOLITTLE. I have no objection to the language, Mr. Chairman, and I am satisfied that a proper interpretation of it can be arrived at.

The CHAIRMAN. In other words, instead of the word "except", insert "provided, however, that insofar as such activities may be peculiar to or primarily"——

Dr. DOOLITTLE. I would have no objection.

The CHAIRMAN. Yes, words along that line.

I think we have a meeting of minds. We are practical men and we know that after an Agency is established, there will follow practical administration. I am aware of that.

The questions that all the members have asked are good questions for the record, but the real solution to our problem is to be by the type of administration.

Now, I notice there is no qualification prescribed for the Director. There are qualifications prescribed for the non-Government members of the Advisory Board, but there is nothing in the statute prescribing what type of qualifications the Director should possess.

Do you think that the committee should address itself to that? What do you think, Dr. Dryden?

As far as I am concerned, you are not to judge my state of mind by the question.

Dr. DRYDEN. I would see no objection to putting in the sort of qualifications that have been talked about, to qualify him in science and technology and administration.

The CHAIRMAN. One may not be a scientist and yet could be a top administrator. I note there is nothing indicating the qualifications of the Director who will be the topman in this bill in its present form, should it be enacted into law, but there are qualifications prescribed for nine of the members of the Advisory Board.

Now, on page 4, I call your attention to the paragraph (b) at the bottom:

> The Board may make recommendations to the President with respect to the appointment of the Director and the Director shall not be appointed until the Board shall have a reasonable opportunity to make such recommendations.

Is that not somewhat of a limitation of the powers of the President of the United States, that he cannot act until some action precedent takes place?

We know the setup with regard to the constitutional position of the President which we have to respect. I assume he would not act without seeking recommendations, but to prescribe that condition as precedent in the law——

Dr. DRYDEN. That was merely quoted from the present National Science Foundation Act. That is the source of it.

I do not remember any specific discussion of it other than they would lift this language from the National Science Foundation Act.

The CHAIRMAN. You do recognize that is a condition precedent to the exercise by the President of the power and duty that he inherently possesses by reason of being President.

Dr. DRYDEN. I would think the same purpose would be accomplished by ending the sentence after the first "Director," the Board may make recommendation.

The CHAIRMAN. I am not posing any objection. I am seeking information.

On page 5:

The Board shall be consulted by the Director.

Now, we are creating a complete organizational setup that is different from the present NACA. Under the present NACA, the Advisory Board is the governing group if they want to be. That is correct; is it not?

Dr. DOOLITTLE. That is correct.

The CHAIRMAN. Now, the Director is at the top?

Dr. DOOLITTLE. That is correct.

The CHAIRMAN. "The Board shall be consulted." If we have this theory of responsibility that is advanced for the appointment of a director, should that not be "The board may be consulted by the Director"?

I assume a wise director would consult the Board, but I am talking about reading into the law now. I think it is well to have any individual man surrounded by good, sensible advisers. I recognize his responsibility, but I recognize how important advice is to those who have responsibility.

I know that from my own position in the Congress of the United States. I am constantly seeking advice. As the majority leader I make decisions, but I am constantly seeking advice of the other Members on legislation coming out of a committee, and in various ways.

Dr. DOOLITTLE. Mr. Chairman, the Board is both a protection for the Director and a group of people who endeavor to assist him in his work. I would much prefer to have the Director himself answer that question.

My own feeling is that it would be better for the Director if he were obliged to consult the Board.

The CHAIRMAN. Then that takes the Board out of an advisory capacity?

Dr. DOOLITTLE. No; if it was not advisory he would be obliged to take the advice.

The CHAIRMAN. He would be an unwise director if he was supposed to do it and it was mandatory and he would not do it. I would not want to be a director under a law that says the Board shall advise and yet I do not have to accept its opinion.

Dr. DRYDEN. I think, Mr. Chairman, the word which causes the most trouble is "prior to" at the end. If it read that: "The Board shall be consulted by the Director on certain matters" without tying it to specific actions of the Director, this would not be a limiting feature.

The CHAIRMAN. I think there is a lot to that.

What do you say, General Doolittle?

Dr. DOOLITTLE. Anything that makes the Director happy makes me happy, Mr. Chairman.

My only interest is to make this Board as useful as it can possibly be to the Director.

The CHAIRMAN. I want to have this a real advisory board if we can keep it in the bill. We are sold on a "bill of goods," so to speak, on the question of responsibility, and if we are going to have responsibility we want to place it definitely.

You think striking out the words "prior to" is sufficient?

Dr. DRYDEN. Yes.

The CHAIRMAN. These questions are simply to inquire for the benefit of myself when we are in executive session.

Now, it also provides on page 4:

> The Board shall make an annual report and from time to time such other reports to the President as it deems appropriate.

This means that the Director makes reports to the President and the Board shall make an annual report and, from time to time, such other reports. That puts in the organizational setup the Director, and then you have the Board making reports also directly to the President. What about that?

Dr. DOOLITTLE. It would seem to me about the only thing that the Board would report would be that it did not like the Director, or question the manner in which he was doing his job.

There is presently, as you know, a report made. That is made to the Congress through the President. Now, there will be two reports made. One by the Director to the Congress through the President, and this will be a report which the board may make to the President, giving their indication as to how the job is going which is in substance how the director is doing his job.

The CHAIRMAN. Well, should not the language be such that the Board shall be required to make reports, and so forth, through the Director, the line of command?

Dr. DOOLITTLE. No, sir; I think that would defeat the purpose of this.

Dr. DRYDEN. I have not consulted the Chairman on this, but I think I suggested before that if that sentence or requirement were omitted the Board would make whatever reports to the President they felt necessary without having a requirement that they make reports once a year.

Dr. DOOLITTLE. I would be happy with that.

The CHAIRMAN. Will you repeat that again?

Dr. DRYDEN. Eliminate the whole sentence, then the Board will make whatever reports it thinks necessary; that it is not required to make an annual report.

The CHAIRMAN. Also put a period after the word "director" on line 23?

Dr. DRYDEN. Yes, sir.

The CHAIRMAN. Doctor, I am going to address a question to you. I listened to you on Meet the Press Sunday night. Often times on programs of that kind we Members of Congress get more information than we do otherwise.

Dr. DRYDEN. They won't like your characterization of the program. It was Face the Nation.

The CHAIRMAN. That is right. I have been on that program several times.

I notice that the program has a habit of getting you big dignitaries.

In the course of it, you said negotiations and discussions are now underway with ARPA in connection with the transfer of activities which may come within the twilight zone that the General has so well described.

Are you in a position now to enlighten the committee as to what the discussions are? If not, I do not want you to.

Dr. DRYDEN. I was going to put in the record a statement as to those negotiations. They are not completed as yet, but I can make a progress report and I can get that to you, Mr. Chairman.

The CHAIRMAN. That will be perfectly satisfactory, Doctor.

(The information referred to follows:)

MAY 12, 1958.

Hon. JOHN W. McCORMACK,
Chairman, Select Committee Astronautics and Space Exploration,
House of Representatives, Washington, D. C.

DEAR MR. McCORMACK: During the hearings before your committee, when I appeared as a witness, the request was made that I submit a statement regarding the status of negotiations between the National Advisory Committee for Aeronautics and the Department of Defense.

Attached is such a statement.

You also requested that I submit a statement regarding the qualifications of the Director of the proposed National Aeronautics and Space Agency. I believe he should be experienced in science or technology and in the administration thereof.

Sincerely,

HUGH L. DRYDEN, *Director.*

STATEMENT REGARDING NEGOTIATIONS BETWEEN NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS (NACA) AND ADVANCED RESEARCH PROJECTS AGENCY (ARPA), DEPARTMENT OF DEFENSE (MAY 9, 1958)

As agreed upon between the Department of Defense and NACA, the initial program for NASA will provide for major effort in three principal areas of interest as follows:

(1) Effective use of unmanned space vehicles instrumented to collect information of value to the scientific community including properties of the upper atmosphere and outer space that affect flight and influence terrestrial phenomena such as weather and communications.

(2) An orderly development of the science, technology, and equipment required for manned space flight. Flights of a man in satellites or on more extended missions are not contemplated during fiscal year 1959, but laboratory and flight investigations including animal experiments to establish the principles by which manned space flight will be accomplished must be undertaken now with great urgency.

(3) Research and development on advanced components and new techniques will be emphasized to provide a continuous increase in the national capability in space technology. Unmanned satellite flights and elementary lunar probes are being accomplished with existing rockets, auto pilot, guidance systems, and structures developed as a part of the ballistic missile program.

As more difficult space missions are attempted they will require even larger and more sophisticated rocket systems, more accurate guidance systems, and auxiliary power systems for long duration flights New tracking, communication, and surveillance systems will be required for both ground and flight use.

In implementing the program, the existing launching area at Cape Canaveral and the proposed Missile Test Center at Camp Cooke will also be used for launching of space vehicles. New facilities will also be required. The NACA range at Wallops Island is to be equipped for the launching of small satellite vehicles

and for the subsequent monitoring and tracking of the flights. Instrumentation at the island will be expanded and improved as required for the expanded program.

New rocket test facilities for research on larger high energy fueled rockets will be required and these will be located at the rocket test center at Edwards Air Force Base.

The existing tracking facilities used in the IGY program will be developed and additional tracking sites will be established at latitudes north and south of the existing sites for tracking satellites on polar orbits. Additional tracking, instrumentation, and guidance stations will be required for flights in equatorial orbits. Some portable launching, tracking, and instrumentation stations will be constructed for use in special probing flights from widely dispersed locations.

Ground facilities for the development and evaluation of flight guidance and control systems will be constructed. The equipment will be investigated in a ground environment simulating as closely as possible that of space.

Military programs.—Programs that are predominantly military include reconnaissance and surveillance, countermeasures against space vehicles and jamming, special weapons effects in space, navigation aids, and space surveillance in connection with early warning and defense.

Civil programs.—Programs that are primarily civil include unmanned space flights to obtain scientific data such as vertical probes, lunar and interplanetary probes, scientific satellites with associated data acquisition and analysis.

Programs under discussion.—Programs still under discussion include man-in-space programs, the million-pound-thrust engine, and special purpose chemical engines, communications, and meteorological survey and research.

(Dr. Dryden also submitted the following material:)

Face the Nation

As broadcast over the CBS Television Network, April 27, 1958, 4:30 to 5 p. m.; CBS Radio Network, April 27, 1958, 9:30 to 10 p. m.

Guest: Dr. Hugh Dryden, Director, National Advisory Committee for Aeronautics.
Moderator. Stuart Novins.
Panel:

John Madigan, Chicago American.
Charles von Fremd, CBS News.
Jack Raymond, New York Times.

Producer. Ted Ayers.

Mr. Novins. A new civilian space agency has been proposed by President Eisenhower: It would be responsible for all civilian space science development and exploration. Secretary of Defense McElroy has told Congress that the man who is expected to be named as Director of this new agency is Dr. Hugh Dryden, who is currently Director of the National Advisory Committee on Aeronautics.

Dr. Hugh Dryden is here now to Face the Nation.

Dr. Dryden, the world is on the threshold of the space age, and if all goes as indicated, you will be the man probably with the key to perhaps the biggest door. We want to know what is behind that door and how you intend to walk through it.

So if you are ready, sir, let's take the first question from Mr. Madigan.

Mr. Madigan. Doctor, we are already spending billions of dollars and plan to spend billions more in military and research pursuits. Is this space race worth the cost?

Dr. Dryden Mr. Madigan, I think it is a cost that we will have to bear for the economic and military future of our country and the free world.

Mr. von Fremd. I wondered, Doctor, going along with this matter of costs, is there any pressing reason from the military standpoint right now why we should beat Russia to the moon.

Dr. Dryden. I think the aspect of the race with the Russians that we should think of is to think in terms of the analogy of an Olympic meet in which there are a very great many events. I don't think that even our country has the money to do everything possible that we can think of to do in space. What we must do is to demonstrate the capability to do any of these things.

Now, a flight to the moon does demonstrate certain capabilities in the way of rocket boosters, in the way of guidance equipment, which show that we would have the capability to do a great many other things as well.

Mr. RAYMOND. Are you suggesting, Doctor, that it would be sufficient merely to show that we can do this and not go ahead and do it, not build a base on the moon, not to try to circle the moon?

Dr. DRYDEN. I hope I am not misunderstood this way. We must choose the things which seem to be the best goals for our country, and not think that we have to follow everything which may be suggested by the Russians.

Mr. MADIGAN. Doctor, some witnesses up on the Hill have taken the stand it would probably be worthwhile to let the Russians accomplish it first. I think the term they used would be like adding something to Siberia, that it would be useless, and the cost to them would possibly help us in a general way.

Dr. DRYDEN. I think the difficulty with this idea is that we do not know that it will be useless We do not know what the results of such exploration will be. I compare it with Columbus setting out from Spain. He set out for a very different purpose from that what he accomplished.

Mr. MADIGAN. Can you place a pricetag now, looking long range into this unknown, as to what the cost will be?

Dr. DRYDEN. It is very difficult to fix an overall pricetag. I think we can say that unless we are willing to spend some hundreds of millions of dollars consistently over a period of years, we will not be able to accomplish very useful results.

Mr. NOVINS. When you say "over a period of years," Doctor, how do you place a limit? How do you ever stop, once you start?

Dr. DRYDEN. Well, have we stopped in aeronautics from beginning with the Wright brothers airplane? I think we are beginning a new age of space. I do not think we are going to accomplish all these wonderful things all in a moment, but we are beginning on a long road, and I don't, myself, look for the expenditure in this area to ever cease. I think we will have commercial applications of space.

Mr. VON FREMD. Dr. Dryden, you say that it is important that we show that we have the capability of reaching the moon. Dr. Wernher von Braun has said we must learn to creep before we walk.

Dr. DRYDEN. Yes.

Mr. VON FREMD. And walk before we run, and therefore has suggested that we send a man 150 miles up in space.

Dr. DRYDEN. Yes.

Mr. VON FREMD. I understand, however, sir, that you feel that this would be tantamount to, say, shooting a woman out of a cannon. How can you bring these two points of view together.

Dr. DRYDEN. Yes, I think the remark was taken a little bit out of context and was not addressed specifically to Dr. von Braun's proposal. There have been many similar proposals including some from within the NACA.

The problem is this. We must set ourselves a goal which is further away and more important than that. What I said was to shoot a man from the air vertically and bring him back by parachute contributed only a relatively small amount of information. We get a few minutes of weightlessness for the human occupant, compared to a little less than a minute we now have. The one who plans this program to get man in space, which I would define as man in orbit, has to consider whether the expense of this particular step is worth the cost, whether it contributes enough in knowledge.

We know, for example, that it contributes very little to the reentry problem because the reentry from satellite speeds in space starts at 18,000 miles an hour, or more, whereas the man here comes to rest and starts from zero, under conditions that are quite different.

Mr. VON FREMD. And you still feel Dr. von Bruan's proposal really does not have sufficient scientific weight?

Dr. DRYDEN. Dr. von Braun proposed this as part of a very extensive program which would cost on the order of a billion and quarter per year as I recall it, and I think the problem will be, having known what you are going to have available to accomplish your goal, whether you want to spend your money this way or whether you want to take a step which is a little further in advance.

The next step is to toss the man like the ballistic missile warheads down on Florida and to actually reproduce some of the latter part of the reentry conditions.

Mr. RAYMOND. Dr. Dryden, I would like to raise another question. A great deal has been said about the necessity of civilian control of space programs. Now why is civilian control so necessary? After all, the military put the satellites up. The military conduct most of the space work and probably have the first need for some of these space vehicles.

Dr. DRYDEN. If I could remember the various points, one of the points is the fear that the scientific aspects of space, the use of satellites for the scientific investigation of the universe, will not receive very much attention within the military group.

The second is the announced desire of the President to undertake international peaceful activities in space, and many people feel that if we start with an organization in Defense, it will be very difficult to arrange any international peaceful activities in space.

Mr. RAYMOND. I am not thinking in terms of the organization you have. I am thinking in terms of the control itself. There is an implication that the military now is not controlled by civilians And besides this point that you make about the military not paying attention to the pure science of it, well presumably they did when they got the satellites up.

Dr. DRYDEN Well, the proposal before the Congress is not that a civilian control all aspects of space work. The military aspects are still in the hands of the Department of Defense, and in my opinion there will be a great many projects which are of concern to both military and civilian use. Take communications as one. And in many of these areas I think there will be cooperative projects.

Mr. RAYMOND How do you have a cooperative project if the military has most of the operational need?

Dr. DRYDEN. Well, we have several such projects. The X-15 is a cooperative project with the Department of Defense in which our organization has technical control, the preliminary laboratory experimentation, sat in jointly on decisions as to the contractors to be selected, and we will obtain that airplane and fly it. There will be both Air Force and civilian pilots flying this airplane. This is an example of a cooperative project with the military which has been very successful. The X-1 airplane, all of these have been cooperative with the military.

Mr. NOVINS Doctor, the language setting up or proposing this new agency seems to be a little bit vague as to the organization, the function and the purpose of the agency. How do you visualize the organization of it? What will it comprise.

Dr DRYDEN Mr. Novins, the bill provides for a director as the chief executive officer to be appointed by the President with the advice and consent of the Senate. It provides for an advisory board of 17 men of whom 8 should be, not more than 8, from Government agencies.

The object of it is to bring to bear the experience of persons in other Government agencies who have interests in this problem, to bring in experience in the many fields of technology and science and public affairs that are concerned with the space problem.

Mr. NOVINS. As you see it now, Doctor, what current needs does this fill? Why isn't the present structure of research sufficient? Where are the weaknesses now that this new agency will attempt to correct?

DR. DRYDEN. At the present time the space satellite program will terminate at the end of the International Geophysical year. There is no provision to support the development of the scientific apparatus for making measurements in space.

Mr. NOVINS. But you have an existent organization, Doctor, do you not?

Dr. DRYDEN. We have an existent organization, but the scientific organization would normally go out of existence without any funds

Mr. NOVINS Why do you need a new agency? Why can't there simply be a request for new funds?

Dr. DRYDEN. I don't know Whether I understand exactly what is implied by the question. It is quite possible to set up all space work under the Department of Defense

I have tried to cover the reasons that have been stated for separating out the civilian aspects from the Department of Defense, and there have been proposals as you know, for a completely new agency.

What the bill provides is a new agency, but using as its nucleus a collection of people, facilities, facilities valued at some $400 million, $350 million, about 2,000 scientists who have been working in teams in these areas for a long time.

Starting with that building block, it is proposed to add by contract operation the people Who are now engaged in this program. It is a means of integrating and bringing together the people concerned with the space science and civil side of the space problem.

Mr. MADIGAN. Doctor, there is some support on the Hill for a commission form of control.

Dr. DRYDEN. Yes.

Mr. MADIGAN. A 5-man commission, 7-man like the AEC.

Dr. DRYDEN. Yes.

Mr. MADIGAN. Rather than a director and a 17-man advisory committee.
Dr. DRYDEN. Yes.
Mr. MADIGAN. Would you oppose a commission?
Dr. DRYDEN. Mr. Madigan, I have testified before the House committee on this subject. I have said I felt that that form of organization gives rise to a great many problems which comes from trying to define the relative responsibilities of 4 or 5 men who are running a single agency.
Mr. MADIGAN. You mean then that a 17-man advisory committee wouldn't be unweildy?
Dr. DRYDEN. The 17-man committee is purely advisory. The director is the principal executive officer, and the purpose of the advisory committee is twofold.
One, to strengthen him before outside agencies, other agencies, if they believe that the program is sound. Second, to protect the President and the Congress by having people who know all aspects of the subject to monitor the operation of the agency.
Mr. MADIGAN. Where in this world do you believe would be the best point from which to launch a space station of some sort?
Dr. DRYDEN. The problem of the launching of satellites, of course, is already solved. You can launch a satellite from Patrick or Camp Cook. There is a slight disadvantage in that launching from Patrick. We cannot launch into polar orbits, and the satellite track moves over the surface of the earth, so, for example, if you wanted to send a man around an orbit once, he wouldn't come back over Patrick. He would come back somewhere else.
Now as you look into the problems of particularly interplanetary probes, it is true to some extent for lunar probes, but not quite to the same extent, you must get a station on the Equator or very near the Equator. The problem is exactly the same as the intercept problem in aerial warfare, shooting from one airplane to another, where it is much simpler to shoot straight ahead and don't try to shoot off at an angle. Launching at any other point than the Equator amounts to shooting at an angle with a very complicated guidance system, and it increases the guidance requirements very greatly.
Mr. VON FREMD. Dr. Dryden, I would like to go back to this previous matter of this new structure, this new agency the administration is requesting. As I understand it now, your present organization, NACA, has over 8,000 employees.
Dr. DRYDEN. Yes.
Mr. VON FREMD. Certainly this new administration or this new agency, if it comes into effect, will employ even more people. Historically insofar as I know, it seems that most of the big scientific breakthroughs come with small projects such as the Manhattan Project. Do you think there is a possibility of this new agency becoming unwieldy because of its size?
Dr. DRYDEN. Mr. von Fremd, it is not contemplated that the existing laboratories which are essentially research laboratories will be greatly increased. The bill is written with the very broad authority to work out cooperative agreements or contracts with or without reimbursement, with all sorts of agencies, governmental, State, and private, and the idea is that substantially all of the expansion will be done by contract with existing groups in industry or in nonprofit organizations
Mr. RAYMOND. Sir, on that point you made about the Equator, are you suggesting that it might be useful for us to try to build a launching platform at the Equator, should we look for the place?
Dr. DRYDEN. This will surely come in the future. It will not be a necessity within the next 5 to 10 years.
Mr. RAYMOND. Is there a point in our proposing such a thing as an international projects perhaps, since we talk about the international use of space?
Dr. DRYDEN. It would be quite useful, since the United States owns very little real estate that is on the Equator.
Mr. VONFREMD. I believe we have already had some difficulty with Mexico in regard to our missile program on our down-range bases. Do you think that the Government should start now negotiating with a Latin American country?
Dr. DRYDEN. I think it is a little bit early. Our immediate needs will certainly be met by the existing launching sites. It may be that there will be some field-type operations, just as our early atomic bombs you recall, we sent out what amounted to a field expedition to occupy a certain position, make a firing and then come home.
Mr. NOVINS. Doctor, what do you consider should be the priority objectives of the new agency.
Dr. DRYDEN. In the first place, let me give a personal opinion that the space research and exploration must be priced in context with other activities. For

myself, the ballistic missile program has the highest priority, perhaps a higher priority.

Now within the space program itself, there are certain very high priority military projects like the reconnaissance satellites. Within the new civil agency the immediate thing is to see that this program of scientific satellites is continued, to see probably by cooperation that we begin work on larger boosters for future space activities, especially those in which you are considering putting man into space.

Mr. NOVINS Doctor, one of the things that sort of catches the imagination of the man on the street is the prospect of sending a man to the moon or a platform to orbit around the moon What kind of a timetable could you guess at?

Dr. DRYDEN. Mr. Novins, there is very little disagreement on the directions in which we are going to move, and a lot of disagreement on timetables and course.

On the 50th anniversary of flight I wrote a little prophesy saying I thought that within 50 years we would have man on the moon. Now 5 years have gone by. I would certainly reduce the 50 years very, very considerably. I don't believe that it is going to be done in 5 years. There are a lot of problems We could put a man on the moon but we couldn't get him back As you know, the Russians are able to put a dog in space. We can put a man in space, but we do not yet know and have not yet demonstrated the means by which we get him back again.

Mr VON FREMD. Dr Dryden, do you think that some of the more enthusiastic supporters of a crash space program are overemphasizing their call for immediate and very heavy action right now to try and have a lunar probe to get a man on the moon, to have spaceships? Do you think they are calling for the expenditure of too much money too soon?

Dr DRYDEN I think it would be far preferable, as I said before, to have assured support over a continuing period than to have a very large amount of money for 1 year and then next year wipe out the whole business, because the money would be wasted that way.

Mr. MADIGAN. What specific shot or action would you need the Equator site for? I don't think you could add that up

Dr. DRYDEN. A Mars probe We now have authorized by the President probes in the neighborhood of the moon. If we want to send a probe in the neighborhood of Mars, we would have to do that, I think, from an equatorial site

Mr. RAYMOND. Sir, do you plan to do any of the major probes of that nature from Camp Cook?

Dr. DRYDEN. I think the present lunar probes will probably be fired from Patrick

Mr. RAYMOND. I gathered from what you said about Cook that Patrick was unsuitable and therefore Cook might be used

Dr. DRYDEN No. Cook is needed if you want a polar orbit We are cooperating in a project to put up a very light inflatable balloon. The one in the program now is 12 feet in diameter. We would like to look to the future for a hundred feet in diameter This is something that could be seen by everyone. You don't have to listen to beeps. You would like to put that up on a polar orbit so that it could be seen all over the world. For that you would go to Camp Cook.

Mr. RAYMOND. Dr. Dryden, you made a prediction about a man in space.

Dr. DRYDEN Yes.

Mr RAYMOND. You also spoke favorably of the commercial use of space.

Dr. DRYDEN. Yes.

Mr. RAYMOND. Would you make a prediction for us about the commercial use of space?

Dr. DRYDEN. Yes. Even these very light balloons, especially if we could get one up 100 feet in diameter, are of very great interest from the point of view of communications, worldwide communications, of using this as kind of a mirror to send up your radio or radar or television and bounce off of this satellite to a point over the horizon from where you are, and as a matter of fact some of our communications companies are interested in looking, in studying this possibility.

The other is weather. You have, perhaps, seen estimates of the economic value of an improvement in weather forecasting. It is really quite startling. I don't remember the numbers, but it is a great many hundreds of millions of dollars, if we could increase the reliability of weather forecasts.

Mr. MADIGAN. Doctor, when the Russians beat us with sputnik there was a lot of alibis to the extent that under the International Geophysical Year the only intention of Vanguard was research, anyway, that we weren't doing it as a military viewpoint.

Do you agree with that viewpoint?

Dr. DRYDEN. Yes.

Mr. MADIGAN. Isn't there a possibility here that you will get wide division between the military and research aspects, if we have it divided now, that Russia will again go ahead and again we will lose the psychological race.

Dr. DRYDEN. I don't think so. We certainly have not had it for 4 years in aeronautics. We have had a research in aeronautics working very closely with the military and civil authorities as well.

Mr. VON FREMD. But you had this problem, though, in the case of the first sputniks and the American rockets, because the Army had claimed that they had the ability to put up the satellite long before the Vanguard could.

Dr. DRYDEN This is old history. I don't know how worthwhile, Mr. von Fremd, it is to rake this over. We made a decision that we would let nothing interfere with our ballistic missile program, that we would start this IGY satellite entirely separate.

Mr. MADIGAN. That is just my——

Dr. DRYDEN. The Russians made the decision that they would put their IGY satellite up with their ballistic missile booster.

Mr. MADIGAN. This is just the point that Charles and I have tried to get at.

Can't you visualize the same conflicts 5 or 10 years from now in relation to a space project, where the military can say, "Well, if that darned research outfit over there down the street weren't fooling around, we could have done this a long time ago"?

Dr. DRYDEN. No, because the booster that this new space agency will use certainly for a good many years will come from the military. The only thing we have to put anything in space are Jupiters, Thors. In a little while it will be Atlas and Titan.

Mr. RAYMOND. Dr. Dryden, that seems to confirm the fears of many that you are simply adding another bureaucratic agency to the existing setup.

Dr. DRYDEN. No, it is another agency which, in cooperation with the military, I visualize myself that the firing of Thors will be done by the same people firing Thors now, that the new agency will be concerned with the things which go in the front end of it very largely.

Mr. RAYMOND. But, Dr. Dryden, you described it, and it is described officially as an advisory committee.

Dr. DRYDEN. No.

Mr. RAYMOND. And there are people in Congress who complain that it won't have any jurisdiction at all.

Dr. DRYDEN. Well, the Advisory Committee of the new Agency is not in control of the program. As a matter of fact, this Director does not have to follow their advice at all. It does give a mechanism for getting the views of a broader group of people who come from many branches of science.

Mr. MADIGAN. But the average American, Doctor, thinks in terms of Mr. Holaday, Dr. Killian, now Dr. Dryden. They say, "What goes on here—4, 5, 6 agencies? They were calling for unification and now they are starting a new one."

Don't you think it would be better if you had one overall agency handling both the civilian and military aspects of it?

Dr. DRYDEN. I don't believe that this will meet all of the needs. It is, of course, possible to combine in one agency. There are only 2, however, not 4. ARPA will handle all space problems within the military, and the new agency would handle the——

Mr. MADIGAN. You say it won't meet all the needs. Are you implying there are some faults, then, in this legislation as the President has proposed it?

Dr. DRYDEN. No. I am saying if you combine all of it under the military, there is a fear that the space science part of it would not be carried through, and that some of these civil uses would not be carried through.

Mr. MADIGAN. Are you saying that the field, the scientific community of which you are a member, is fearful, as Jack Raymond started to say in the very beginning, to let the military have any control in this?

Dr. DRYDEN. Not any control, but——

Mr. MADIGAN. You want to limit them, though?

Dr. DRYDEN. Not have overall control; yes.

Mr. RAYMOND. Dr. Dryden, how would you divide between the military and the civilian in this?

Dr. DRYDEN. This is very simple. We are engaged in discussions with ARPA at the present time to see which of the programs the President has approved will be transferred to the new agency. There is complete agreement that the space science programs in their entirety will be transferred. There is agreement that

reconnaissance satellites will remain in the military and certain other aspects of it, and that there will be joint projects in other areas. Man in space, I think, will be a joint project.

Mr. RAYMOND. But we were talking about pure science a minute ago.

Dr. DRYDEN. Yes.

Mr RAYMOND. These powerful rocket engines that must be devised for space vehicles are applicable both to civilian and in the military.

Dr. DRYDEN. The civilian agency will either buy or be given these boosters by the military In fact, I think if I told you that the civil agency would use the Douglas Aircraft Co. crew to fire the Thors for the space science measurement.

Mr. VON FREMD. That brings up another very important point, I believe, Dr. Dryden, and that is that most of the members of the House Space Committee and the witnesses testifying before it have been concerned over the fact that our initial thrust in our rockets is nowhere near that of the Russians.

Do you believe that we should have, well, possibly not a crash program but a very intensive program to get a rocket that can put up, let's say, a four or five thousand pound payload?

Dr. DRYDEN We want a million pound rocket.

Mr VON FREMD. You want a million pound rocket?

Dr DRYDEN. Most certainly this must be started now if you are going to have it in 5 or 6 years.

Mr. RAYMOND. Dr. Dryden, hasn't it been started?

Dr DRYDEN. No. There have been studies made but there is no active development

Mr RAYMOND. What has been holding you back?

Dr. DRYDEN. The assignment of funds to do it and the choosing of this over other projects.

Mr RAYMOND. By whom?

Dr. DRYDEN. At present the responsibility lies within the Department of Defense

Mr. MADIGAN. Is Russia ahead of us in the space race?

Dr. DRYDEN. They have bigger boosters.

Mr. MADIGAN. Are they ahead of us?

Dr. DRYDEN. Yes.

Mr. MADIGAN. On whom do you place the blame, the Defense Department?

Dr. DRYDEN On all of us, the whole country, ourselves. We did not take this matter seriously. Before sputnik if you mentioned the word "space" your appropriations would be cut for wasting the peoples' money on foolish things.

Mr. MADIGAN. Now it is no longer foolish?

Dr. DRYDEN. This is no longer true, although I must point out that the money has not yet been appropriated.

Mr RAYMOND. Dr. Dryden, you made a speech on the coast yesterday in which you expressed fears that people might forget about our space needs and go back to automobiles and color TV and all those things.

Dr. DRYDEN. I think this is a very real fear.

Mr. RAYMOND. Suppose we pose another choice, the choice between a huge bill for space development and school construction.

Dr. DRYDEN. Well, this is the choice that confronts the country and the people's elected representatives are going to have to make that kind of a decision. The rate at which this goes forward will be determined by what decisions are made. Now we know the Russians have made their decision. They haven't stopped since after the war, have been pushing right straight ahead.

Mr. VON FREMD. You say you believe Russia is ahead of us now. How long will it take us to catch up?

Dr. DRYDEN. A few years. I don't know how to specify it any closer than that.

Mr NOVINS. Doctor, I am sorry we won't have a chance to follow that up with you a little more. We would like to very much, but our time has run out.

Many thanks indeed for coming here to Face the Nation, and thanks also to today's panel of newsmen, Jack Raymond of the New York Times, Charles von Fremd of CBS News, and John Madigan of the Chicago American. This is Stuart Novins. We invite you to join us again next week at this time for another edition of Face the Nation.

Our program originated today in Washington.

(Produced by Ted Ayers; associated in production, Bill Kobin; directed by Bill Linden.)

The CHAIRMAN. By the way, General, what do you think about a commission form of agency?

Dr. DOOLITTLE. I much prefer the form submitted in the bill.

The CHAIRMAN. I have an urgent message from the Speaker, but I want to ask one more question before I must leave.

Of course, there is a provision in this bill showing that this agency is likely to expand in the future. I am in agreement with that. I can project my mind and see that this might be the basis of a centralization or coordination of many research activities on what might be called the civilian side.

There are two things there. One, on your request, with the approval of the Agency. Then the concurrence of the President, approval of the President.

There are two double vetoes there.

Dr. DRYDEN. I would say there is encouragement for the two people concerned to get together. If they cannot, there is the opportunity to take it to the President.

The CHAIRMAN. Of course, we should start out with the President anyway. He has the power anyway.

Dr. DRYDEN. He has the power to order anyway.

The CHAIRMAN. You would have no objection to that particular section of the bill being worded in accordance with our constitutional setup?

Dr. DRYDEN. None whatever.

The CHAIRMAN. Now, there is one other aspect, Doctor. You asked for a waiver of the civil-service requirements on the payment of salaries. I will start out by saying I am an enthusiastic supporter of it. What would be the problem if we were to report it out in this bill?

Dr. DRYDEN. The other agencies will hope that you will do the same for them.

The CHAIRMAN. We could act on this because it is a major part, a most important part of the bill, which is the establishment of a new agency. But I do not think we could go across the board and put in there provisions that would apply to scientists and technicians in other agencies.

Dr. DRYDEN. We have written to the other committee, Mr. Chairman, the Post Office and Civil Service Committee, and offered to appear before them and deal with this proposal.

The CHAIRMAN. Do you not think you had better take that whole question up when you go before that committee, rather than having it included in here with the human dissatisfactions that will result in other agencies?

Dr. DRYDEN. I do not want it to fall by the board because the Agency would be almost inoperative without such a provision.

Mr. KEATING. Mr. Chairman, we probably would have jurisdiction to include them all if you would clear it with the chairman of the Committee on Post Office and Civil Service.

The CHAIRMAN. Of course, that is true. Unless that were done it could result in some serious complications.

Dr. DRYDEN. I would hate to see you drop it from the bill, hoping that an amendment is going to be offered by the other committee because I don't think we would get the consideration of the question quickly then. The Agency would be inoperative without it. We would be in desperate shape.

The CHAIRMAN. What about the scientists and technicians employed in other agencies?

Dr. DRYDEN. Most of them with whom I have discussed this question are glad to see somebody pioneer. They rejoice that the problem has been recognized at all.

The CHAIRMAN. I can understand that.

In other words, if you get it in your Agency; they then will have something to hang on to, but what about the raiding that might take place of other agencies? I use that not sinisterly, but in a descriptive way.

Dr. DRYDEN. The plans for the Agency do not involve large increases in Government personnel. I should say that it would be in the order overall of a thousand people of which 200 would be scientists. So most of this expansion is through the contract procedure.

I am saying that the plans certainly do not contemplate a large expansion of the present research facilities with Government employees. The expansion is going to come through operations under contract which do not involve this particular question of raiding.

The CHAIRMAN. If the committee should keep that provision in, it would be quite an inducement for scientists It could be an inducement for scientists and technicians in other agencies who are getting lower salaries than those in your Agency to try to get into your Agency.

Dr. DRYDEN. Mr. Chairman, there are a number of people in other agencies who have called on me who wish to work in the space field.

The CHAIRMAN. I am not saying that the mere salary is the inducement. But it is a very important factor in the lives of all of us. We just cannot disregard it.

If that should be kept in, will you promise the select committee that you will not permit the raiding of other agencies?

Dr. DRYDEN. Most certainly. We have to work with these other people.

The CHAIRMAN. Will you promise the select committee you will cooperate with the other agencies to try to induce the proper standing committees of the House and Senate to change it if it should require it?

Dr. DRYDEN. I certainly will.

The CHAIRMAN. I see the purpose and, as far as I am concerned, I am agreeable. The only question to my mind is one of relativity.

Dr. DRYDEN. We have been working on this program for NACA a long time before there was any discussion of space, and we have made very little progress internally.

With this we have persuaded the administration that this is a necessity if this Agency is going to operate.

Now, the problem is to persuade the Congress that if the Government is to have capable technical people they have to come somewhere near meeting the outside pay scale.

The CHAIRMAN. I started out enthusiastically in support of the bill, but I heard many witnesses testify as to what might be left for the other agencies to do and my enthusiasm started to wane. I am equally frank in saying that as a result of General Doolittle's testimony I am back on the path of enthusiasm now.

Mr. BROOKS (presiding). Mr. McDonough, of California, is recognized.

Mr. McDONOUGH. I am very happy to see you here, General Doolittle. We have great pride in the fact that you come from California and that you attended high school in my district, at the Manual Arts High School.

Dr. DOOLITTLE. Yes, sir.

Mr. McDONOUGH. We know of your great contribution to the science of aeronautics and your new interest, your encouragement in the development of astronautics.

I notice in your statement, which is characteristic of your great confidence in the United States, on page 4, you state:

> The fact that the Russians may accomplish some specific objectives in their space program first should not in itself be permitted to divert us from our designated objectives.

That, I think, is a policy that we should all adopt because we have an objective. We have a purpose. We should not be diverted from our goal by sensational things and the fact that we will have failures from time to time should not discourage us too much.

In that respect, let me ask you this:

You undoubtedly have perhaps as much knowledge as anyone else, being Chairman of the Advisory Committee on Aeronautics, as to the potential manpower in scientific intelligence in this country at the present time to meet the objectives that we have. Do we have such manpower and, in your opinion, are we moving as fast as we can or should at the present time, in space technology?

Dr. DOOLITTLE. We have the manpower, sir. I believe that a program of coordinating that manpower will enable us to move as fast as we should.

I do not believe that we are doing it now.

Mr. McDONOUGH. Do you believe that this Agency which the bill provides should be the parent body that will develop the basic research and provide the specifications for future development on space technology?

Dr. DOOLITTLE. Yes, sir.

Mr. McDONOUGH. Do you think it should encompass and have authority over, or maintain close cooperation with, such organizations as the National Science Foundation and the Weather Bureau?

Dr. DOOLITTLE. Yes, sir.

Mr. McDONOUGH. I notice that you recommend, and I am inclined to agree, that more than one military representative should be on the Board; that the Agency should be civilian controlled and be devoted to the development of space technology for civilian interests and for peacetime purposes.

Dr. DOOLITTLE. Yes. It will, however, support the military in many ways.

Mr. McDONOUGH. I do not disagree with that a bit.

However, the basic philosophy in this country is the civilian control of military or, at least, have authority over it, and in this instance it should also apply?

Dr. DOOLITTLE. Yes.

Mr. McDONOUGH. You believe that this Agency ought to absorb the NACA and include it in its authority?

Dr. DOOLITTLE. It should absorb the duties of the NACA; the personnel of the NACA, and the facilities of the NACA.

Mr. McDonough. And then expand from there into space technology?

Dr. Doolittle. I do not believe it will be necessary to greatly expand the governmental facility, but it will expand largely through contracting outside the Government.

There will be some increase required in the NASA administrative organization because of the new duties that it will take on.

Mr. McDonough. Do you recognize a great difference between space or astronautics and aeronautics?

Dr. Doolittle. I consider that they form a spectrum and there is a great difference between the two ends of the spectrum, but they grow together in the middle.

Mr. McDonough. You mean that the development of aeronautics at the present time leads into astronautics?

Dr. Doolittle. Yes, sir.

For instance, the NACA is presently spending almost half of its time directly or indirectly on matters that help in astronautics. That has been a direct outgrowth of their work in aeronautics.

Mr. McDonough. Now, as to our industrial capability in this country to produce the materials necessary for security in space and scientific investigation and exploration of space, do you think that we have all the facilities that we need in this country for that purpose?

Dr. Doolittle. I think we will continue to have additional facility requirements, but most of those will be obtained from industry and from research organizations and from the universities.

To answer your question directly, I do not feel there is an immediate requirement for more governmental laboratories.

Mr. McDonough. To what extent should this Agency act in the operating field in the production of hardware and material for experimental purposes?

Dr. Doolittle. I believe they will get much of their hardware from the military initially and that they will contract for that hardware that they do not get from military to industry.

Mr. McDonough. Do you think we should add an incentive in this bill for encouragement of scientific manpower to come to the Government for work in this industry and to aid us?

Dr. Doolittle. I would not quite know how to go about it.

Mr. McDonough. I mean some more attractive salary proposals?

Dr. Doolittle. That is in here.

Mr. McDonough. I mean the average employee, to encourage the young man.

The upper echelon is provided for in the bill. I refer to the average scientist, engineer, meteorologist.

Dr. Doolittle. The greatest incentive is increased pay.

Mr. McDonough. That is right. Do you think that the bill should provide that?

Dr. Doolittle. I do not believe it is necessary to write it out in the bill. I believe the ability to meet pay outside of Government is in the bill, and that is all that is required.

Mr. McDonough. Thank you very much, General Doolittle. I appreciate your appearance here.

Mr. Brooks. Mr. Keating.

Mr. Keating. General Doolittle, you occupy a prominent place in minds and hearts of the people of our country. You occupied such

a place first during your courageous exploits in World War II, and you have been deep in our hearts and minds recently.

The importance of what you say here is indicated by the influence you have had on our chairman.

At the present time as Chairman of the Committee, as I understand it, the Director reports to the President through you?

Dr. DOOLITTLE. Yes, sir; at the present time.

Mr. KEATING. Why do you feel it is desirable to change that to have the Director of the new Agency report directly to the President?

Dr. DOOLITTLE. I do not believe that it makes a great deal of difference whether the Board of the new Agency is advisory board, or executive board.

I believe in the old agency it functioned very well as an executive board. In this new Agency it is desired that the Director should have complete authority in order that he might operate as expeditiously as possible. I imagine that there was a feeling that if the Board remained an executive board there might be some delay entailed and that the Director might not be able to operate as rapidly.

With the Advisory Board there is no possibility of delay.

Mr. KEATING. Has delay been encountered under the existing setup?

Dr. DOOLITTLE. I would rather you ask the Director that question.

Dr. DRYDEN. Under the existing setup a great many powers have been delegated by the present Board. I think there was a feeling of the drafters of the bill that you should not leave that chance.

In other words, the Board is not required to delegate the Director and, therefore, the organization is composed in the way you have it in the bill so there is no possibility there would be this situation where there was delay.

Mr. KEATING. You have a personal preference as to the method of administration, General Doolittle?

Dr. DOOLITTLE. You mean whether it be an executive board or advisory board?

Mr. KEATING. Yes.

Dr. DOOLITTLE. My original opinion was that it should be an executive board because that operated so well. I am satisfied, however, that the importance of getting this legislation through and getting on with the job is far more important than whether the Board should be executive or advisory.

Consequently, I am now very happy with an advisory board.

Mr. KEATING. But you adhere to the view personally that the executive board would be preferable?

Dr. DOOLITTLE. It has been. It has operated very effectively in the past. That is a compromise. I think it is a good compromise, and I am now in favor of it although my original contention was that the executive board was better.

Mr. KEATING. There has been considerable discussion here about a commission as opposed to a board, General Doolittle, a commission of, let us say, five members with a chairman.

You favor this setup?

Dr. DOOLITTLE. I favor this type contained in the bill for several reasons. First, I like the direct clear-cut authority which the Director has.

Secondly, I like to have all the agencies with whom the director is involved periodically at hand so that he can consult with them.

This occurs in this type of board. It will not occur in the five-man commission type.

Mr KEATING. Except by some liaison arrangement?

Dr. DOOLITTLE. The liaison here is automatic.

Mr. KEATING. Under this setup it is automatic?

Dr. DOOLITTLE. Yes. I would say also that with a board of this kind, none of whom draw any pay, all of whom are interested in the work, that the Government is able to get very useful people working for it for nothing.

Mr. KEATING. That is certainly true in the NACA, not the least of whom is our present witness.

The bill as proposed says that the Chairman shall come from the public members only. There has been some discussion on that. Do you think that limitation should be in the bill, or should it be possible to appoint the Chairman from the people in Government?

Dr. DOOLITTLE. Personally I do not feel that it would make any great difference if a governmental member were appointed Chairman, but there would be the feeling certainly that it was possible for the Chairman, if he came from Government, to speak for his agency and this is obviated by having him not come from the governmental 8, but from the civilian 9.

Mr. KEATING. There has been a suggestion made that there is a danger in selecting public members, of having a conflict of interest and particularly if the Chairman were from the public members, that such conflict of interest might be greater than his conflict of interest if he were from Government. Do you have any comment on that?

Dr. DOOLITTLE. First, I would like to say that great value has come from the industry members. They have brought a great deal of knowledge and help to the Board and to the Director.

Secondly, I would say in the past it has been customary to select a chairman from other than industry members.

For instance, to go down the list of Chairmen, first was General Scriven and Dr. Durand, Dr. Freeman, Dr. Walcott, Dr. Ames, Dr. Bush, Dr. Hunsaker, and now myself.

They have always been selected from other than strictly industry members and have thus obviated the possibility to which you refer.

I still do not feel it is a hazard, however.

Mr. KEATING. If the arrangement is made as suggested here, the Director reports as the head of this Agency to the President, and I appreciate your comments with reference to the present creation of a Department of Science, in which I concur at present.

I think personally such a time will come, but I do not think it is here yet.

If this Director reports to the President, is this not of sufficient importance that he should participate in the formulation of policy at the very highest level by attending Cabinet meetings and sitting with the National Security Council?

Dr. DOOLITTLE. As long as the President has a science adviser, Dr. Killian, who sits at these high-level meetings, I do not think it is necessary that the Director of the NASA sit there.

Mr. KEATING. What would be the relationship if the President's scientific adviser continued in office, if this were not a temporary

arrangement and he continued there? What would be his relationship to the Director of this Agency?

Dr. DOOLITTLE. That would be entirely determined by the authority that the President chose to give to his science adviser.

Mr. KEATING. You do not think it would be appropriate in this legislation for us to deal with that question?

Dr. DOOLITTLE. No, sir.

Mr. KEATING. I agree.

Regarding the liaison with the military, there has been a suggestion made that we should spell out in the bill itself the terms of that liaison. Do you agree with that, or do you take the position that we should simply perhaps put in a pious declaration to the effect that liaison should take place?

Dr. DOOLITTLE. Some liaison presently takes place at the level of the executive board. The liaison will continue to take place at the level of the advisory board.

Liaison also takes place before main committees and in various subcommittees. It might even be desirable at some later date to have a decision committee that would be made up of Dr. Killian, a senior member from the Department of Defense, the director of the NASA, Chairman of the AEC, and the Director of the National Science Foundation, to decide just exactly how the jobs would be allocated because they are the five primary agencies involved.

Now, that requires no legislation. If that becomes necessary, the President can appoint such a committee to do that job.

I do not feel that legislation is required.

Mr. KEATING. Would you repeat, please, the personnel of this proposed decision committee as you suggested?

Dr. DOOLITTLE. I would envisage a decision committee where there was any lack of report between the agencies primarily involved in the space program and that would be Dr. Killian, who is the President's science adviser; it would be a senior member from the Department of Defense, probably the Deputy Secretary of Defense, Mr. Quarles; the director of the NASA, who we presume will be Dr. Dryden—I certainly feel that he is the man in the United States most capable to do that job—the Chairman of the Atomic Energy Commission, Admiral Straus, and the Director of the National Science Foundation, Alan Waterman. They are the individuals who are, in my mind, primarily involved. They are all at the decision level.

Then, for instance, this gray area of which we spoke—any point on what should go to the NASA, what should go to the military, what should go to the National Science Foundation—then those problems can be resolved by that high-level committee.

But again no legislation is required, the President could appoint such a committee.

Mr. KEATING. You feel they are the best qualified men to reach such a decision?

Dr. DOOLITTLE. Yes, sir.

Mr. KEATING. I think that is very significant, General Doolittle. I think that is a very helpful suggestion, although I would agree that it would be inappropriate for us to embody anything of that kind in this legislation.

Now, liaison particularly with the military, you would agree, would have to take place at all levels at present?

Dr. DOOLITTLE. It does presently.

Mr. KEATING. The Atomic Energy Act sets up, in rather precise form, the manner by which that liaison should be accomplished.

Do you think we have reached the point in this Agency where we should endeavor to do that in this legislation, or should we wait until things have been at work for a while?

Dr. DOOLITTLE. I do not think anything is required in legislative form at this time.

Mr. KEATING. It would be better to wait and see what is needed in the form of such a liaison committee?

Dr. DOOLITTLE. Yes, sir.

Mr. KEATING. It has been asserted that this committee simply could be spinning its wheels here since authority exists for nearly all space projects either in the military or in NACA or in other agencies.

I do not share that view. I think the creation of this Agency is of extreme importance but that has been asserted here by several.

Would you comment on that, General?

Dr. DOOLITTLE. I believe it is a very useful committee, sir.

Mr. KEATING. Do you think that the Agency is useful or is it essential?

Dr. DOOLITTLE. It is a very useful concept. I feel the Agency will do an outstanding job.

Mr. KEATING. Will the Agency do a better job than these separate departments or elements of Government would do on their own without an Agency?

Dr. DOOLITTLE. They will do a better job and do it more quickly and do it more cheaply.

Mr. KEATING. How important do you think it is that we take a shot at the moon within this year?

Dr. DOOLITTLE. I would, rather than say arbitrarily that we take a shot at the moon, say that we would establish a comprehensive program, that program will go ahead for the purpose of achieving instrumented flight in space as quickly as possible.

I would say that a quick shot at the moon, as a stunt, would not be of great value, and it would be of great value only if it fitted in as an integral part of this comprehensive program.

As a matter of fact, at the present time there are substantial reasons why we should not take a shot at the moon. The moon happens to be, we presume, a very clean place. The scientific fraternity is very anxious to keep it so, without contamination, until by instrumentation or manned exploration we can find out more about it.

Mr. KEATING. You do not think that the rumored Russian shot at the moon, so called, should deter us from our program in any way?

Dr. DOOLITTLE. That is one of the things that I would say should not deter us from a well-thought-out program.

Dr. DRYDEN. Mr. Keating, may I say there are, as you know, three lunar probe shots authorized. I think that what is expected there is to get in the vicinity of the moon, to test out certain ideas on guidance and certain scientific equipment that may be included in the front end. These are programs that have already been authorized in this interim period.

Mr. KEATING. Is it intended to take pictures of the moon?

Dr. DRYDEN. This is one proposal. I am not familiar with the exact contents of the program.

Mr. KEATING. Does the lunar probe involve equipping with cameras or television equipment the vehicle which we send up?

Dr. DRYDEN. I do not know whether I would use exactly that word. Certainly in the early shot, because of the relatively small payload, it will be primitive form of camera and television system.

Mr. KEATING. General, I was very much interested in your statement, with which I heartily concur, that we must arrive at an international agreement for the peaceful uses of outer space.

Do you not agree that we must preliminarily reach such an agreement as to how high the sovereignty you might say of each nation is to extend? That is the first thing to agree upon, is it not?

Dr. DOOLITTLE. Yes, sir.

Mr. KEATING. Do you not think it would be helpful for this country to take the lead in encouraging such an international conference for that purpose?

Dr. DOOLITTLE. I do.

Mr. KEATING. Would you think it better to suggest that the United States do this separately or to suggest that it be done through the United Nations?

Dr. DOOLITTLE. It would seem to me that through the United Nations would certainly be the proper place to start because all nations are involved in space whether they are in it yet, or not.

Mr. KEATING. Of course, all nations are not in the United Nations.

Mr. DOOLITTLE. It certainly is an excellent forum with which to start.

Mr. KEATING. You share my view that the United States should absolutely and with reasonable dispatch make such a suggestion to other nations?

Dr. DOOLITTLE. Yes, sir.

Mr. KEATING. Just finally, we had a little talk about the name of this agency and I share your view it does not make much difference what the name is, but of course, in fixing on a name in this city we have to find a combination of initials that will sound good.

Now, NACA becomes NASA. If we had this one that Congressman Fulton suggested, it would be the NAAA. Now, that would not be very good. I should think the importance of this is pretty much just about that important, to get some initials that will stick in peoples' minds. Beyond that the name makes very little difference.

Dr. DOOLITTLE. I am pleased to have the word "advisory" out because it is a misnomer. I do not believe that the name should actually say something that is not so.

On the other hand, it should say as much as possible what the agency actually does.

Mr. KEATING. There are quite a few ideas that come to mind, but I guess I had better defer those.

Dr. DOOLITTLE. I believe the aeronautics should be in there because we are going to continue the aeronautical field.

Mr. KEATING. You think it is important to have the word "aeronautics" in there?

Dr. DOOLITTLE. Yes, sir.

Mr. BROOKS. Mr. Ford.

Mr. FORD. I have no questions.

Mr. BROOKS. Mr. Feldman.

Mr. FELDMAN. General, I believe you stated earlier that the first function of the new agency NASA was to spell out a program.

Dr. DOOLITTLE. Yes, sir.

Mr. FELDMAN. Has such a program been spelled out?

Dr. DOOLITTLE. Dr. Dryden is working on that. I would like to have him tell you what he has done.

Dr. DRYDEN. There is a plan under formulation in the final stages. It will be submitted very shortly to the Bureau of the Budget.

I think until some action is taken there I would rather not bring it into the committee. I can tell you the general nature of it.

Mr. FELDMAN. Can you give the summary of the program?

Dr. DRYDEN. Would you like me to put it in the record, Mr. Feldman?

Mr. FELDMAN. I do not mean at the moment.

Dr. DRYDEN. We can put that in the record, without money attached to it, just the subjects which are included in the program we are discussing.

Mr. FELDMAN. That will be satisfactory.

(The material referred to follows:)

PROPOSED PROGRAM OF NATIONAL AERONAUTICS AND SPACE AGENCY

I. Unmanned space flights to acquire scientific data:
- A. Vertical probes.
- B. Satellites to study space environment.
- C. Lunar probes.
- D. Planetary and interplanetary probes.
- E. Weather reconnaissance.
- F. Communications developments.
- G. Astronomical observations.

II. Investigations of manned space flight:
- A. Small-scale recoverable orbiter.
- B. Vertical flight and reentry vehicles.
- C. Manned orbital and reentry vehicles.
- D. Supporting biological studies.

III. Research and development on advanced components and techniques:
- A. Propulsion systems:
  1. Development of special rocket motors using conventional propellents.
  2. Development of high-energy rocket motors.
  3. Initial contract development of million-pound thrust rocket motor.
- B. Vehicular subsystems:
  1. Auxiliary power supplies.
  2. Controls.
  3. Communications.
  4. Displays.
  5. Personnel equipment.
  6. Guidance systems.
  7. Computers.
- C. Instrumentation.
  1. Vehicle-borne scientific instruments.
  2 Tracking systems.
  3 Telemetering systems.
- D. Vehicles
  1 Stabilized satellite space platform.
  2. Propulsion and subsystems test vehicles.

IV. Research facility requirements
- A. Adaptation of pilotless aircraft research station for handling large liquid-fuel rocket motors.
- B Extension of instrumentation facilities.
- C. High-energy rocket research facilities.
- D. Guidance and control facilities.

V. Personnel and operating expenses:
- A. Administration.
- B. Research and supporting staff.
- C. Travel.

Mr. Feldman. Earlier in your testimony, General, you spoke of the fact, if I understood you correctly, that there is at present pending legislation to increase the present NACA board from 17 to 19 members and to add to that board members from the Department of the Army which would make it 6 from the military in all. Is that not so?

Dr. Doolittle. The present membership of the board is 17. The Army originally had representation, 2 from the Army and 2 from the Navy.

In 1947, when the unification bill was passed, the Air Force came on and took over the two Army places. Since that time the Army has not had representation on the main board.

As they have gotten into the air and space age, it seems that they should have representation. So we have requested legislation giving representation to the Army. That would give them 2 places also and then the board will have been increased from 17 members to 19 members.

Mr. Feldman. You are satisfied with the present operation of NACA, is that not so?

Dr. Doolittle. I am very proud of the present operations of it.

Mr. Feldman. And the board functions as the executive authority of the agency?

Dr. Doolittle. It has operated very well.

Mr. Keating. Would the gentleman yield at that point, please? General Doolittle, one thing I neglected to ask you is this:

There was some discussion here of the Presidential directive to the Defense Department and to your agency for addition of powers. Are you at liberty now to release the text of that directive so that it may be incorporated in the minutes?

Dr. Doolittle. It is my understanding we are. I have a copy of memorandum for the Secretary of Defense, Chairman, the National Advisory Committee for Aeronautics, dated April 2, which I will be very pleased to leave with the committee.

Mr. Keating. I suggest, Mr. Chairman, that be made a part of the record.

Mr. Brooks. It will be placed in the record.

(The material referred to follows:)

The White House,
Washington, April 2, 1958.

Memorandum for: The Secretary of Defense Chairman, the National Advisory Committee for Aeronautics.

I have today transmitted to the Congress a special message recommending the establishment of a National Aeronautics and Space Agency. A draft of legislation carrying out this proposal is being transmitted to the Congress by the Director of the Bureau of the Budget.

The new Agency will be based on the present National Advisory Committee for Aeronautics and will continue that agency's well-established programs of aeronautical research. In addition, the new Agency will be responsible for programs concerned with problems of civil space flight, space science, and space technology. The instructions outlined below are concerned with these new activities.

The ultimate potentialities of space flight cannot now be fully grasped. Since some of these potentialities are clearly of significance from the standpoint of our national security, the Department of Defense will have a continuing interest in the programs to be undertaken and will continue to sponsor programs which may

be peculiar to or primarily associated with military weapons systems or military operations as well as certain research and development which may be of a general supporting character Furthermore, I desire that the skills and experience that have been developed within the Department of Defense be fully utilized in support of civil space programs. However, it is appropriate that a civilian agency of the Government take the lead in those activities related to space which extend beyond the responsibilities customarily considered to be those of a military organization

I consider it especially felicitous that the National Advisory Committee for Aeronautics will provide the basic organization on which the new Agency will build. Not only does the National Advisory Committee for Aeronautics itself already have a firm understanding of the key problem areas involved and a tested method of approaching such problems, but also this organization and the Department of Defense have long enjoyed a highly productive working relationship. This relationship will ease the period of transition that lies ahead and will provide a basis for the close cooperation that will be needed to solve the difficult problems that will be encountered. It is intended that the new Agency continue to perform for the Department services in support of military aeronautics and missiles programs of the type now performed by the National Advisory Committee for Aeronautics and also provide similar services with respect to military space programs; the Department, in turn, will provide support essential to the success of the new Agency.

In order that necessary work proceed without loss of momentum pending enactment of the proposed legislation, in order that interim measures may be consistent with the intent of this legislation, and in order that implementation of the legislation, when enacted, may be promptly initiated, I desire that the Department of Defense and the National Advisory Committee for Aeronautics take the following actions:

1. The National Advisory Committee for Aeronautics should prepare and present to the appropriate committees of the Congress a full explanation of the proposed legislation and its objectives

2. The National Advisory Committee for Aeronautics should proceed to formulate such detailed plans as may be required to reorient its present programs, internal organizations, and management structure to carry out the functions to be assigned to the National Aeronautics and Space Agency, including the functions now being performed by the National Advisory Committee for Aeronautics, and should also plan and propose such additional actions and programs as may be necessary to implement the proposed legislation. Such actions would include determination of any requirements for additional staff, facilities, or funds that may be needed in the immediate future.

3. The Department of Defense and the National Advisory Committee for Aeronautics should jointly review the pertinent programs currently under way within or planned by the Department, including those authorized by me on March 27, 1958, and should recommend to me as soon as possible which of these programs should be placed under the direction of the new Agency. The Department of Defense and the National Advisory Committee for Aeronautics should also prepare an operating plan to assure adequate arrangements for utilizing in support of the new Agency, either by cooperative arrangements or by transfer to the new Agency, appropriate organizations, facilities, and other functions now within the Department. These actions should be taken in the light of the fact that the proposed legislation contemplates that the new Agency will be given responsibility for all programs except those peculiar to or primarily associated with military weapons systems or military operations.

Supporting research and development should be coordinated to provide for the needs of both military and civil programs without unnecessary duplication. It should be noted that Public Law 85–325 authorized the Department of Defense for a period of 1 year to engage in advanced space projects designated by me. The 1-year period will come to a close February 12, 1959. Since the new Agency will absorb the going organization of the National Advisory Committee for Aeronautics, it should be capable of assuming direction of appropriate programs prior to that date.

4. The National Advisory Committee for Aeronautics should discuss with the National Science Foundation and the National Academy of Sciences, as well as other governmental and nongovernmental bodies, the matter of participation of the scientific community on a continuing basis in planning and coordinating the scientific programs for the use of space vehicles in civilian space science. The best scientific judgment available in determing space science objectives should be

utilized. Matters related to dissemination of the data collected should also be considered.

5. The Department of Defense should identify and report to me what programs now appear to be needed in support of well-defined military requirements. It is understood that the Advanced Research Projects Agency will continue to serve as the focal point for such programs within the Department.

Any problems that may arise in carrying out these interim instructions should be discussed with my Special Assistant for Science and Technology or with the Bureau of the Budget, as appropriate.

DWIGHT D. EISENHOWER.

Mr. BROOKS. May I interrupt counsel for the moment?

In withdrawing the two representatives of the Army from the Board, was that done as a corollary or at the same time that the mission of the Army in aeronautical work was limited to short-range missiles?

Dr. DOOLITTLE. No, sir; this was done in 1947 when the unification bill became law.

Mr. BROOKS. Why was the Army withdrawn from that?

Dr. DOOLITTLE. Because the Air Force at that time was given the air mission.

Mr. BROOKS. And the Army had no air mission at all at that time?

Dr. DOOLITTLE. That is correct, except I believe, liaison.

Dr. DRYDEN. They were never on the committee.

Mr. BROOKS. I know when the Air Force was made a separate entity, it had representation and it took over the Army unit.

Dr. DRYDEN. That is right.

Mr. BROOKS. That is all, Mr. Feldman.

Mr. FELDMAN. Yesterday, Admiral Raborn told us about the Polaris project. He pointed out the striking similarity between that project and the old Manhattan project. He is doing this unusual job which could be in many ways likened, and which he likened, to the spaceship job that an agency of the Government could undertake, and he is doing this under a directive from the Secretary of the Navy.

There was no special legislation necessary to accomplish this purpose. Other than the several relatively minor provisions in the new proposal, is it not possible for for the NACA to undertake that kind of function under its present legislative authority?

Dr. DOOLITTLE. To develop a project like Polaris?

Mr. FELDMAN. That is right.

Dr. DOOLITTLE. Well, the first requirement would be to have money. Then you have to have the authority. We lack the authority and the money to do it.

Mr. FELDMAN. Assuming you could to to the budget and have the Budget Bureau approve such a project, money for such a project, would legislation then be necessary?

Dr. DOOLITTLE. The subject is really academic because if we went to the budget and asked for authority to ask for money to start a development such as Polaris, we would be thrown out.

Dr. DRYDEN. We don't have the authority to buy an airplane, much less develop one.

Mr. FELDMAN. So that it takes this special legislation and a new charter to give the new Agency that authority?

Dr. DOOLITTLE. That is right.

Mr. FELDMAN. Now what is your understanding of the functions of liaison between an agency? Isn't it something that should be continuous and constant?

Dr. DOOLITTLE. The relationship between what?

Mr. FELDMAN. Your understanding of the word "liaison"; isn't it something that should be continuous and constant?

Dr. DOOLITTLE. My understanding of the word "liaison" is that it is a working relationship between two agencies.

Mr. FELDMAN. And it usually is continuous; is that not so?

Dr. DOOLITTLE. It need not be continuous, but it must be available when required.

Mr. FELDMAN. Is it not usually required when there is a continuous relationship between two agencies?

Dr. DOOLITTLE. I do not understand the question.

Mr. FELDMAN. For example, the military here would be tied up pretty closely with the new Agency?

Dr. DOOLITTLE. Yes.

Mr. FELDMAN. And they will require almost continuous reporting on what is going on in NASA, the new Agency that will be set up?

Dr. DOOLITTLE. We have military people in our laboratories so that there is continuously liaison at the present time.

Mr. FELDMAN. Is that by law?

Dr. DRYDEN. No, not by law.

Mr. FELDMAN. Would there be any harm in amending the law so that it would require it?

Dr. DRYDEN. As I testified before, I certainly have no objection if the committee wishes to do that.

Mr. FELDMAN. What percentage of the principal NACA work is military in character?

Dr. DOOLITTLE. A large percentage.

Dr. DRYDEN. It is a matter of definition. About 15 percent is on specific military projects, on airplanes, missiles, engines, by name.

Now you have a broad program of applied research which can be used on military airplanes or civilian airplanes. A great part of it is motivated by the problems which are only at the present moment encountered by military airplanes.

In other words, no civil aircraft is now flying at Mach 3, for example.

We have extensive applied research programs on aircraft at Mach 3. So you can state this narrowly as 15 percent on specifically military project support, or on behalf of the military.

The other extreme is 15 percent which is future, pure science, if you like.

In between you have 70 percent of applied research which you can interpret as applicable to both, perhaps half or three-quarters of it is motivated by the problems which at present come only in military aircraft and missiles.

Mr. FELDMAN. I do not think the answer is too responsive, but I suppose it cannot be.

Dr. DRYDEN. What is your definition of military? What is military research? You do research on a problem of a wing section for an airplane. You can use that wing section on a military airplane or civilian airplane.

Mr. FELDMAN. Where do most of these requests come from, Doctor?

Dr. DRYDEN. The requests for specific work originate in the military. Most of the program for applied research comes through the military, civilian staff members of our subcommittees and from the laboratories themselves.

We have an independent responsibility at present to guess what is coming, to try to see that the information is available when the military needs it.

Mr. Brooks. May I interrupt there for just a moment. The second bell has rung on the floor. We are going to have to go.

I was wondering how many more question you have, Mr. Feldman?

Mr. Feldman. I do have a number of questions. I dislike having the gentleman remain over because I know he has something pressing this afternoon.

Mr. Brooks. We have no alternative ourselves.

Is it possible to submit the questions to the general to answer them?

Dr. Doolittle. I would be pleased to stay and answer the questions directly.

Mr. Brooks. Counsel asks permission to file these questions in the record and the general has agreed to answer those questions in response to the request. If there is no objection, that can be done.

Now I would suggest also that if Mr. Feldman wants to communicate directly with you and will tell you just exactly what information he wishes in the record in response to the question, it might help.

We will not be able to maintain a quorum. I know everybody wants to vote and we have no alternative.

General, on behalf of the committee, it has been delightful to have you here and you have really helped the committee a great deal with your most valuable testimony.

I think it will have a far-reaching effect upon the people of the country. We also want to thank the other gentlemen, Dr. Dryden, and Mr. Dembling, for their assistance. The committee will adjourn until 2:30, and at that time we have Dr. Joseph Kaplan and Dr. Allan T. Waterman, who will be witnesses.

The committee is recessed until 2:30.

(The questions and answers referred to follow:)

Replies of Dr. James H. Doolittle, Chairman, NACA, to Written Questions of George S. Feldman, Director and General Counsel, Select Committee on Astronautics and Space Exploration, United States House of Representatives, May 5, 1958

Question 1. In your opinion, should research into the problems of space flight be under civilian or military control? For what reasons?

Answer. Research into all but the strictly military aspects of space flight should be under civilian control. Control should be in the area of principal interest. Only there will it get adequate support.

Question 2. The President's bill provides (sec. 2) for exclusively civilian control "except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations * * *" (p 2, lines 7–9).

(*a*) Approximately what proportion of the activities of the outer-space agency do you anticipate would come within that exception? A substantial part? Only a small part?

(*b*) What would your answer have been if the exception read:"* * * pertaining to weapons systems or military operations"?

Answer. (*a*) A relatively small part. (*b*) A larger part.

Question 3. Assuming, for example, that the outer-space agency could take over the Vanguard and Redstone projects, under its contract and lease authroity (p. 8, subsec. 6 (5)) or its transfer authority (p. 15, sec. 8), should it do so, in your opinion, or should those projects remain under military control?

Answer. It might take over Vanguard but not the missile part of Redstone. These points are under discussion now and will be decided in conference between agents of the DOD and the NASA.

Question 4. In your opinion, to take a further example, what agency should have charge of developing a 1-million-pound-thrust rocket? The outer-space agency? ARPA? AEC?

(According to testimony by Secretary McElroy on February 26, 1958, before the Senate Preparedness Investigating Subcommittee, the Air Force has charge of this project.)

Answer At present there is no obvious military requirement for a 1-million-pound-thrust rocket. There is a civilian requirement. It should therefore, be developed by NASA. If it is to be nuclear powered, this should be done in collaboration with the AEC.

Question 5 The President's bill contains authority to operate as well as to develop and test aeronautical and space vehicles (see p. 6, lines 1 and 2; p. 7, lines 7 and 8).

(*a*) In your opinion, does the outer-space agency need such authority?

(*b*) Does the NACA have authority to operate aeronautical vehicles?

Answer. (*a*) Yes. (*b*) At present the NACA operates aeronautical vehicles in connection with their research programs.

Question 6. In the light of your experience with the NACA, would you favor a policymaking committee for the outer-space agency or merely an advisory board such as the President's bill provides (secs. 4 and 5)?

Answer. The policymaking committee concept has worked very well for the NACA. The committee has been able to both help and protect the Director. I personally like the concept but think it much more important to get on with the enactment of the legislation requested by the President than to quibble about this point.

Question 7. The President's bill provides (subsec. 6 (b) (2) for rates of pay "which are reasonably comparable with prevailing rates paid by non-Federal employers for similar work" (p. 7, lines 1 and 2).

(*a*) In your opinion, is this provision necessary? For what reasons?

(*b*) It has been suggested that an authorization for a substantial number (perhaps 200 or 300) scientific and professional positions at $12,500 to $19,000 would be adequate. Do you agree? (The NACA now has a small number (30?) of such positions)

Answer (*a*) Yes This provision is necessary so that the pay scales for NASA Government and contract operated laboratories will be on the same basis. (*b*) No. It should apply to all hard to obtain and retain personnel.

Question 8. The Atomic Energy Act contains: (*a*) rather detailed provisions (ch. 11, secs 121–125) for international arrangements and cooperations; and (*b*) provisions for indemnification up to an aggregate amount of $500 million and for limitation of liability (sec 170).

In your opinion, should the President's bill be amended so as to include similar provisions?

Answer. (*a*) Dr. Dryden, in response to your committee's request, has prepared a draft covering this question. With this I agree. (*b*) I have no objections to inserting such provisions.

(Thereupon, at 12:25 p. m. the committee recessed until 2:30 p. m., same day).

AFTERNOON SESSION

The CHAIRMAN. The committee will be in order.

We are very glad to have with us, as the next witness, Dr. Alan T. Waterman, Director of the National Science Foundation. You may proceed, Doctor.

STATEMENT OF DR. ALAN T. WATERMAN,[27] DIRECTOR, NATIONAL SCIENCE FOUNDATION, ACCOMPANIED BY JAMES M. MITCHELL, ASSOCIATE DIRECTOR, AND WILLIAM HOFF, GENERAL COUNSEL

Dr. WATERMAN. Mr. Chairman and members of the committee, I am very happy to appear before you today to give my views on matters relating to the need for efforts to accelerate our progress in space research, technology and exploration, and more particularly regarding proposed organizational arrangements within the Government for this purpose.

At the outset let me state that I heartily endorse the general outline of H. R. 11881, H. R. 11882 and S. 3609, which I believe are before you.

The establishment of a new civilian agency appears to me to be the best method for carrying out the objectives desired. This is particularly true since the new agency could retain the successful experience and excellent relationships of NACA.

In addition, in my opinion, the importance of this subject is such as to justify its assignment to a particular agency with the specific purpose assigned to it here.

In this way the hard-won lessons of the past will assist us to make the most rapid possible progress in developing the means for exploration and of actual flight in outer space.

Furthermore, the vast new horizons that will be opened up by progress in this area of sceintific activity are of concern to very many segments of the national community; they include, but stretch far beyond purely military considerations.

Finally, a civilian-led program would place this country in a position to cooperate with other nations with respect to conquering the problems of space exploration, and would better assure a cooperative world reaction than would an effort conducted by the military.

The impetus for a determined effort is the direction of space exploration was, as you know, provided by the International Geophysical Year.

The Comite Special de l'Anne le Geophysique Internationale passed a resolution in 1954 encouraging any nation if possible to put a satellite in orbit during the International Geophysical Year.

As you know, this challenge was accepted by the United States and later by the U. S. S. R.; as a result both countries have succeeded in placing satellites with different characteristics in various orbits.

As the world appears clearly to recognize, we stand on the threshold of a truly impressive phase of exploration. For the first time man is

able to reach beyond the confines of his own planet. As yet we can have no clear idea where this type of exploration may lead.

However, the logical thing is to limit our declared goals to immediate exploration of the new region of space which is now available, to study it carefully and make a sound determination of the value and feasibility of further steps in exploration and travel.

It must be recognized at once that this is a large and complicated undertaking. In order to succeed we must carry on highly competent research and development in the perfection of various types of rockets and rocket systems, the vehicles to be transported, and maintain close observation and tracking of these vehicles; if possible, communicate with them, which would be another step.

We must likewise continue to push forward research into the most effective means of communication with space vehicles and into their recovery or the recovery from them of their packages of one sort or another, which are the result of observations they make.

Scientific observations made from all types of space vehicles such as rockets, satellites of the type already launched, space platforms, etc., will be of very great importance.

Among the fields of science which will profit tremendously by the use of space vehicles beyond our atmosphere are thorough observations of the sun, which include analysis of the light, heat, radio waves and X-rays from the sun, together with study of the various particles, electrified and otherwise, which may be emitted from the sun.

These are highly important in our analysis of conditions upon the earth, specifically since these observations and analyses are certain to have a profound effect upon such matters as our knowledge of weather and climate on the earth and their fluctuations and upon radio communication.

As a matter of fact, of course, we are entirely dependent on the sun and always have been. The more we can know about the nature and behavior of the sun, the better off we are with respect to our whole environment. The sun and the earth are what scientists would call a system, a giant engine in which the sun delivers heat and many things to us and this fluctuates somewhat. The earth receives it in part and reflects it away in part, so our fundamental knowledge of what goes on in the earth is necessarily conditioned by our knowledge of the sun.

In the past this knowledge has been very imperfect indeed because we only see the sun as though through a dark glass; namely our own atmosphere, which lets through the visible light that our eyes have become adapted to see but stops nearly everything else from the sun.

Therefore, we must get outside this blanket before we can really have a clear idea of what the sun is composed of and about its behavior.

More generally speaking, full knowledge of what the sun sends to us will in time undoubtedly make possible advances in our fundamental knowledge of our earth and the history and future of the solar system.

Similar observations which are essentially astronomical in nature will be highly significant in the study of the planets in our solar system and the stars in our galaxy and the other galaxies.

In fact, undoubtedly the most important opportunity that astronomy has ever had will be the setting up of a fair-sized astronomical telescope on a space platform so as to observe the heavenly bodies

for the first time clearly and without interference from our atmosphere, and to study their complete spectra in detail.

Other observations of great importance concern the detailed study of the magnetic field of the earth and its variations, the existence and location of streams of electrified particles in our neighborhood, and the detailed study of the shape of the earth and the distribution of its mass, which comes from accurate tracking of satellites.

Finally, observations of our planet itself from this distant vantage point will undoubtedly prove to be of great advantage to our fundamental theories concerning weather and climate.

This comes from such observations as the extent of cloud cover over the entire earth and its variations, the location and behavior of storms, especially violent ones such as hurricanes and the like.

Of great importance to space exploration will be studies of the existence and behavior of clouds of cosmic dust, micrometeorites, or other foreign bodies; and of course the study of cosmic rays and other effects which may be damaging to the contents of space vehicles, whether instrument or human.

I should like to point out that the scientific interest, of course, is very high in this type of observation, from space platforms and various types of space travel. Take, for example, what I mentioned about the study of distant stars, the most distant galaxies millions of light-years away.

As you know, a light-year is the distance light travels in 1 year going at the rate of 186,000 miles a second. These galaxies are not involved in space travel obviously because we cannot start out to move even with the velocity of light, much less travel for a million years. But this research is most important to astronomers and, as such, these observations to be made from space platforms fit into the general subject of astronomy together with the whole field we are now studying, radio astronomy and other types of astronomy, so this forms an important niche in our whole present field of astronomy.

The same thing is true of cosmic rays. Now cosmic rays are important to study for the sake of space exploration and travel because, if too intense, they may damage the instruments or the materials of the space platform.

That must be looked into. They also may be extremely dangerous to possible passengers. Now, those are practical reasons. Apart from that, if we can get out in outer space, as we can and are doing now, and study the nature of the cosmic rays in detail, the sizes of the particles, what kinds, how fast they are going, what they are doing, this becomes a part of theoretical physics, nuclear physics which we want to know more about.

In this way the observations to be made from the space platform are very important for the study of science as a whole, and the part played by these observations will take its place among the general interests in fundamental science. Those are quite important reasons.

Thus it is seen that space exploration will involve essentially two types of research which merge one into the other: (*a*) Research which is necessary to the accomplishment of space exploration; and (*b*) pure research employing space vehicles as observing stations.

Both types are involved in the present IGY satellite program and in those which are planned for continuation.

As you know, the National Science Foundation has had the responsibility on behalf of the United States Government for securing and administering the funds for the scientific programs in the International Geophysical Year, including the satellite program, and for the coordination of this scientific work by Government agencies, while the general operation of the United States IGY program has been in the hands of the United States National Committee for the International Geophysical Year in the National Academy of Sciences National Research Council which also provides coordination with other countries.

From what I have said, it will be noted that the opportunities provided by space exploration will be very strongly scientific in character and civilian rather than military, although, of course, military requirements form a part of any general program, and are reported in their own right.

For these reasons, may I repeat my strong conviction that the program, except for its military portion, should be in the hands of a civilian organization such as proposed in the present bills.

Because of its past responsibilities with respect to the purely scientific aspects of studies in outer space and because of its general responsibilities for basic research in the sciences, the National Science Foundation expects to cooperate in the planning and execution of basic scientific research which may be carried out by the use of space vehicles devised by the new Agency.

This would be in accord with Executive Order 10521 which outlines responsibilities of various agencies for the support of basic research and is exactly what we understand the bill contemplates.

The CHAIRMAN. Doctor, at the opening of your statement you say, "I heartily endorse the general outline" of several bills. What about your specific views on them?

Dr. WATERMAN. That was intended to be a rather wholehearted endorsement of the present bills, Mr. Chairman. I do not see there are many details that one might find fault with. It perhaps is a large board which is authorized to advise the Director for quick decision and management, and there it is a matter, of course, of the balance of representation on the board and the difficulty of dealing with a large body or securing a quorum in a large body.

Matters of that sort are matters of opinion and I think can be solved quite well when the new Agency faces its responsibilities.

The CHAIRMAN. Will there be any duplication of work on the part of this new Agency with the National Science Foundation? Will it be in competitive fields?

Dr. WATERMAN. I think not, sir. As I stated at the end of my statement, the National Science Foundation would expect to cooperate fully with this Agency in view of its responsibility for general scientific research of a basic nature and the fact that we have already been following this in the current IGY program. So one could be sure of our cooperation with this Agency, Mr. Chairman.

The CHAIRMAN. With the establishment of an agency along the outlines of the bill, do you understand that some of the activities of the National Science Foundation would be taken over by the new Agency?

Dr. WATERMAN. We would have no responsibilities specifically with respect to any such things as developing space vehicles, rockets, guidance, and the usual things, and the research going with that.

The area where we might cover the same kind of ground is in the matter of research performed by the space platforms. There, quite clearly, this Agency would be responsible for research related to the means of exploring space, the environment in which the vehicles travel, the effects that would have to be discovered to find out if anything would interfere with their flight.

The possibilities of traveling to the moon, say, or ultimately to another planet would have to be things they deal with. There would have to be basic observations with respect to that.

We, too, are interested in that, but not from the standpoint of space exploration—rather from the standpoint of the knowledge of science, what is contributed by such observations, as illustrated by the telescope I mentioned which could be mounted on a space platform.

The new State Agency would be interested in precise observations concerning bodies that might be approached or are to be reached in space exploration and what sort of conditions would be encountered.

We, on the other hand, would find that in our astronomy program similar information would be very welcome to the astronomers and observations of very distant stars, places where there is presently no possible hope of every traveling those distances.

In those cases we would expect to include such research in our general program and advise and cooperate with the new Agency in that territory.

Whether this needs to be spelled out, Mr. Chairman, any further is a matter of your decision, of course.

The CHAIRMAN. I note from your statement that the National Science Foundation has been designated as a representative of the United States during the IGY year.

Dr. WATERMAN. Yes, sir.

The CHAIRMAN. If this new Agency is established, would you expect the new Agency to represent the United States or the National Science Foundation?

Dr. WATERMAN. I have heard no mention of the new Space Agency taking such a part. Of course, it is not in existence yet. But the present discussions among the different nations have been as follows: that the international body concerned with the International Geophysical Year, has decided against continuing the International Geophysical Year.

At the same time, they have had under active discussion suitable programs that could be considered after the IGY. Among those is this matter of space research. Another is oceanography. Another is research in the polar regions.

Those may come to a head and we may be asked whether the United States would become a party to similar programs in special areas as a matter of continuing operations rather than just for one particular year like the IGY.

Space research is one of those. Since the National Science Foundation is already involved in the IGY space research program we could act in a similar capacity with respect to that, if the situation arose again, just as we might in other areas of cooperative international research.

Now, if that happened, there would have to be, of course, an understanding between us and the new Agency as to just who would handle this and how.

The CHAIRMAN. What is Executive Order 10521, Doctor?

Dr. WATERMAN. That is an Executive order of the President, dated 1954, entitled "Executive Order Concerning Government Scientific Research, the National Science Foundation, and the Interdepartmental Committee for Scientific Research and Development." In effect it is an Executive order which clarifies the responsibilities of Government agencies in the field of basic research and in scientific research and development.

The CHAIRMAN. Do you have an extra copy there?

Dr. WATERMAN. Yes, sir.

The CHAIRMAN. Without objection, it may be inserted in the record at this point.

(The document follows:)

[Reprinted from the Federal Register of Friday, March 19, 1954]

MARCH 17, 1954—EXECUTIVE ORDER CONCERNING GOVERNMENT SCIENTIFIC RESEARCH, THE NATIONAL SCIENCE FOUNDATION, AND THE INTERDEPARTMENTAL COMMITTEE FOR SCIENTIFIC RESEARCH AND DEVELOPMENT

TITLE 3—THE PRESIDENT

EXECUTIVE ORDER 10521

ADMINISTRATION OF SCIENTIFIC RESEARCH BY AGENCIES OF THE FEDERAL GOVERNMENT

Whereas the security and welfare of the United States depend increasingly upon the advancement of knowledge in the sciences; and

Whereas useful applications of science to defense, humananitarian, and other purposes in the Nation require a strong foundation in basic scientific knowledge and trained scientific manpower, and

Whereas the administration of Federal scientific research programs affecting institutions of learning must be consistent with the preservation of the strength, vitality, and independence of higher education in the United States; and

Whereas, in order to conserve fiscal and manpower resources, it is necessary that Federal scientific research programs be administered with all practicable efficiency and economy; and

Whereas the National Science Foundation has been established by law for the purpose, among others, of developing and encouraging the pursuit of an appropriate and effective national policy for the promotion of basic research and education in the sciences

Now, therefore, by virtue of the authority vested in me as President of the United States, it is hereby ordered as follows:

SECTION 1. The National Science Foundation (hereinafter referred to as the Foundation), shall from time to time recommend to the President policies for the Federal Government which will strengthen the national scientific effort and furnish guidance toward defining the responsibilities of the Federal Government in the conduct and support of scientific research.

SEC. 2. The Foundation shall continue to make comprehensive studies and recommendations regarding the Nation's scientific research effort and its resources for scientific activities, including facilities and scientific personnel, and its foreseeable scientific needs, with particular attention to the extent of the Federal Government's activities and the resulting effects upon trained scientific personnel. In making such studies, the Foundation shall make full use of existing sources of information and research facilities within the Federal Government.

SEC. 3. The Foundation, in concert with each Federal agency concerned, shall review the scientific research programs and activities of the Federal Government in order, among other purposes, to formulate methods for strengthening the administration of such programs and activities by the responsible agencies, and to study areas of basic research where gaps or undesirable overlapping of support may exist, and shall recommend to the heads of agencies concerning the support given to basic research.

SEC. 4. As now or hereafter authorized or permitted by law, the Foundation shall be increasingly responsible for providing support by the Federal Govern-

ment for general-purpose basic research through contracts and grants. The conduct and support by other Federal agencies of basic research in areas which are closely related to their missions is recognized as important and desirable, especially in response to current national needs, and shall continue.

SEC. 5. The Foundation, in consultation with educational institutions, the heads of Federal agencies, and the Commissioner of Education of the Department of Health, Education, and Welfare, shall study the effects upon educational institutions of Federal policies and administration of contracts and grants for scientific research and development, and shall recommend policies and procedures which will promote the attainment of general national research objectives and realization of the research needs of Federal agencies while safeguarding the strength and independence of the Nation's institutions of learning.

SEC. 6. The head of each Federal agency engaged in scientific research shall make certain that effective executive, organizational, and fiscal practices exist to insure (a) that the Foundation is consulted on policies concerning the support of basic research, (b) that approved scientific research programs conducted by the agency are reviewed continuously in order to preserve priorities in research efforts and to adjust programs to meet changing conditions without imposing unnecessary added burdens on budgetary and other resources, (c) that applied research and development shall be undertaken with sufficient consideration of the underlying basic research and such other factors as relative urgency, project costs, and availability of manpower and facilities, and (d) that, subject to considerations of security and applicable law, adequate dissemination shall be made within the Federal Government of reports on the nature and progress of research projects as an aid to the efficiency and economy of the overall Federal scientific research program.

SEC. 7. Federal agencies supporting or engaging in scientific research shall with the assistance of the Foundation, cooperate in an effort to improve the methods of classification and reporting of scientific research projects and activities, subject to the requirements of security of information.

SEC. 8. To facilitate the efficient use of scientific research equipment and facilities held by Federal agencies:

(a) the head of each such agency engaged in scientific research shall, to the extent practicable, encourage and facilitate the sharing with other Federal agencies of major equipment and facilities;

(b) a Federal agency shall procure new major equipment or facilities for scientific research purposes only after taking suitable steps to ascertain that the need cannot be met adequately from existing inventories or facilities of its own or of other agencies; and

(c) the Interdepartmental Committee on Scientific Research and Development shall take necessary steps to insure that each Federal agency engaged directly in scientific research is kept informed of selected major equipment and facilities which could serve the needs of more than one agency. Each Federal agency possessing such equipment and facilities shall maintain appropriate records to assist other agencies in arranging for their joint use or exchange.

SEC. 9. The heads of the respective Federal agencies shall make such reports concerning activities within the purview of this order as may be required by the President.

DWIGHT D. EISENHOWER.

THE WHITE HOUSE,
March 17, 1954

The CHAIRMAN. What are your views regarding the Director as proposed in this bill and the commission form of agency?

Dr. WATERMAN. That is always a problem in connection with an agency of this kind. There is a tendency for an agency devoted to science to have a commission form because of the greater opportunity for review and discussion of policies and actions.

My own view in this case is that since this is a very urgent matter, if the United States wants to go into space research, and is really determined to make progress, then you really have a mission on which you have to put a great deal of emphasis and drive, and the right way to do it is to have an agency where the director really has the authority and has a board behind him to consult.

In other words, the importance of this job seems to me to indicate that there should be a director with an advisory body rather than a commission. That is my personal view.

The CHAIRMAN. Do you mean important so far as the immediate year or 2 or 3 years—the immediate period ahead?

Dr. WATERMAN. Especially during the years ahead. But this is going to be a very difficult undertaking and it seems to me this importance justifies doing it in a manner which will enable decisions to be made quickly and wisely and with no delay in getting on with the work.

The CHAIRMAN. What is the difference between a director with a board of 17 to advise him—they would have a lot of influence, I am not deceiving myself on that—and the commission form of 5?

I think you would have more expeditious action with a commission of five rather than a board. You have to view this board in the light of history. Now and heretofore they are the top level of management, and they are over the director.

You have that history of thirty-odd years. It is pretty hard to depart from it.

Dr. WATERMAN. Well, this is a debatable matter. There are advantages to both types. The advantages, as you have said, of the commission is that you reduce the decisions to a smaller group. Nevertheless, the group has to make them as a group in the commission type.

In the case where you have a director and an advisory board, the advisory board is after all advisory only. While its advice may be taken very seriously by the director he can, in principle, act rapidly if he has to, and that is the thing which the commission form cannot do quite so well.

The CHAIRMAN. I am inclined to think there is a lot of substance in what you say, in starting out with something new. I doubt very much if it was a new idea that you would have an advisory board of 17. The only strength in favor of it is the historical aspects, so far as I am concerned, and recognizing the exigencies in connection with departure from the historical background of the NACA. But I would imagine this Board would be more than advisers in the new setup.

I think they will have a much more potent effect than just being advisers, having in mind that they have been the bosses for 30-odd years, but I will not ask you about that.

Dr. WATERMAN. I can understand that. You will notice I did say I felt that a board of 17 seems unduly large. I know that is only authorized. My hope is that it would be smaller than that because then it would be much more manageable.

The CHAIRMAN. Of course if we provide for 17, they will have 17, because 8 come from Government departments and agencies and you have to have a majority from outside the Government agencies to maintain the civilian characteristic of the agency.

We can provide it shall be a civilian agency, but everything else we do might make it otherwise.

Dr. WATERMAN. Yes.

The CHAIRMAN. Doctor, have you given consideration as to the military function within its probable field as we view the world today and the immediate future, what there is left for this agency to do other than by permission of the Defense Department?

Dr. WATERMAN. I think they have a great deal to do. After all, the field is wide open in this space research game. The possibilities are very much greater than any the Department of Defense, at least in my opinion, should do.

The CHAIRMAN. The Defense Department might hold that the sending up of satellites is primarily military. Then you realize under the terms of the bill the military makes the decisions, does it not, unless we change the language?

Dr. WATERMAN. If they say that a thing is military in nature, then they have the authority for that part of it. So it depends on how much they claim is military, is that right?

The CHAIRMAN. Suppose there is a difference of opinion between the new agency, whatever it is, and the military? Have you an opinion to express whether they ought to be able to have it resolved by someone else, such as the President?

Dr. WATERMAN. This would have to come to the President, undoubtedly with the advice of his chief adviser on science and technology, Dr. Killian, in my opinion.

The CHAIRMAN. If the new agency said a particular scientific program was essentially a civilian field and the Defense Department says essentially the same program is in the military field, there is a clash.

Should there not be some source of decision as to which one is right?

Dr. WATERMAN. It can only be the President, it seems to me, with such advisory counsel as he has.

The CHAIRMAN. Should there be language in the bill that provides for that?

Dr. WATERMAN. That would be, of course, according to the wishes of Congress, whether there is need for this to be spelled out or whether it would happen anyway. It seems to me that it would happen in any event.

The CHAIRMAN. Now, in your agency are your scientists and technicians under the Classification Act?

Dr. WATERMAN. Most are, but we have authority for exceptions to the civil service regulations in our act.

The CHAIRMAN. Under the bill, this new agency would be excluded, would it not?

Dr. WATERMAN. I believe it has that power, sir.

The CHAIRMAN. What effect would that have on you in relation to those associated with you who are not outside the Classification Act?

Dr. WATERMAN. I don't think that would bother us. You see, we do have the power to make exceptions as well. That takes care of our top positions in the agency.

The CHAIRMAN. You do have the power?

Dr. WATERMAN. Yes, sir.

The CHAIRMAN. With similar language along the lines of that contained in the bill?

Dr. WATERMAN. It is along similar lines.

The CHAIRMAN. When you review your remarks will you put the language in, Doctor?

Dr. WATERMAN. Yes.

(The information follows:)

PROVISION OF THE NATIONAL SCIENCE FOUNDATION ACT OF 1950 RELATING TO APPOINTMENTS WITHOUT REGARD TO THE CLASSIFICATION ACT OF 1949

SEC. 14 (a) The Director shall, in accordance with such policies as the Board shall from time to time prescribe, appoint and fix the compensation of such personnel as may be necessary to carry out the provisions of this Act. Such appointments shall be made and such compensation shall be fixed in accordance with the provisions of the civil-service laws and regulations and the Classification Act of 1949: *Provided*, That the Director may, in accordance with such policies as the Board shall from time to time prescribe, employ such technical and professional personnel and fix their compensation, without regard to such laws, as he may deem necessary for the discharge of the responsibilities of the Foundation under this Act. The Deputy Director hereinafter provided for, and the members of the divisional committees and special commissions, shall be appointed without regard to the civil-service laws or regulations * * *.

The CHAIRMAN. Mr. Brooks.

Mr. BROOKS. Doctor, thus far have you found that the NACA has worked fairly efficiently?

Dr. WATERMAN. Yes, sir, to the best of my knowledge.

Mr. BROOKS. And this organization would be similar, if we adopt this bill without many amendments, to the NACA organization?

Dr WATERMAN. With this difference about the authority of the director, that is right, sir.

Mr. BROOKS. The director in the bill before us would have much more authority. He would really be the operator.

Dr. WATERMAN. As I understand it, he is appointed by the President, yes, sir.

Mr. BROOKS. He would be akin to a mayor who has a council?

Dr. WATERMAN. In a sense.

Mr. BROOKS. And the director would be the full executive director, subject always to consulting with the President and the board?

Dr. WATERMAN. Yes, sir, that is my understanding.

Mr. BROOKS. The change in your opinion is not enough, is it, to feel that we are going to set up an inefficient agency?

Dr. WATERMAN. I think it would be an efficient agency, because it could and would partake of the efficient management and the excellent work done in NACA. I think it would be strengthened actually by the fact that the President appoints the director instead of the director being appointed by the board and responsible to the board.

This means that if one has to do a job fast and thoroughly, that he can act more readily than if he had to depend entirely on his board.

Mr. BROOKS. It puts the Director closer to the President?

Dr. WATERMAN. Yes, sir.

Mr. BROOKS. Instead of being removed one part, he is closer to the President?

Dr. WATERMAN. That is right.

Mr. BROOKS. And if he were a competent man he would feel that he is able to act independently in emergencies?

Dr. WATERMAN. Subject to wise counsel with the President and the Board.

Mr. BROOKS. He could act independently and with dispatch on his decisions?

Dr. WATERMAN. That is right.

Mr. BROOKS. That is why you think it is superior?

Dr. WATERMAN. That is right, Mr. Chairman.

Mr. BROOKS. That is all, Mr. Chairman.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. Dr. Waterman, do you believe it would be an advantage both to the NACA and the National Science Foundation if the National Foundation were represented on the Board of 17?

Dr. WATERMAN. I believe it would; yes, sir. It would be a great help in keeping our policies coordinated.

Mr. NATCHER. We have had that suggestion made to the committee. In fact, one of the witnesses today made that suggestion.

Dr. Waterman, the National Science Foundation was established under the basic act of 1950, isn't that correct?

Dr. WATERMAN. Yes.

Mr. NATCHER. Now there is no conflict as between the National Science Foundation and the new Agency that will be established by this bill. Am I correct in that?

Dr. WATERMAN. I believe that is correct. I mentioned our mutual interest in basic research on the part of these space vehicles and that we have an interest which I believe goes beyond theirs. Some basic science would have probably no effect on space travel, but this is a matter to be worked out between us and I think it will be recognized.

I do not know whether this needs explicit recognition in the act or not, but I think it will be understood. We have general basic programs for scientific research.

Mr. NATCHER. If we presented the bill on the floor some Member might ask the question whether duplication would be there and whether or not we were just establishing another agency.

As I understand the basic act under which the National Science Foundation was established, it was authorized and directed to develop and encourage "the pursuit of an appropriate and effective national policy for the promotion of basic research and education in the sciences," and further—

> to initiate and support basic research in the mathematical, physical, and other sciences by making contracts and other arrangements for the conduct of basic scientific research, and to appraise the impact of research upon industrial development and general welfare.

Dr. WATERMAN. Yes, sir.

Mr. NATCHER. Briefly, that is the basic act?

Dr. WATERMAN. Yes.

Mr. NATCHER. In my opinion, there would be no conflict or conflict that would not be worked out so that this Agency could cooperate under the power invested in it by the new act.

Dr. WATERMAN. As long as the Agency understands our position in this matter, I believe there is no problem.

Mr. NATCHER. Thank you, Mr. Chairman.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. Dr. Waterman, starting on the bottom of page 1 you have this to say:

> Finally, a civilian-led program would place this country in a position to cooperate with other nations with respect to conquering the problems of space exploration, and would better assure a cooperative world reaction than would an effort conducted by the military.

I certainly agree with the statement in general, but I was wondering if you would elaborate a little further as to the desirability of worldwide cooperation in this field of space exploration and how important it might be in our worldwide relations.

Dr. WATERMAN. I think it is most important. It goes without saying when man succeeds in getting out in a new region like this, that this new region should be subject to cooperative exploring.

All the nations should be free to use it. But in order to take full advantage of the opportunity for scientific exploration of space, the cooperation of the nations that have the capacity to do it, it seems to me, is essential.

Not only that, but it is a means of promoting cooperation and good will which is quite important.

Mr. SISK. Do you see any problem under our present system of classification of information? To what extent do you feel we might be a little freer in the exchange of information, particularly in the field of space research?

Under the military program we are constantly faced with this problem. I was wondering what you think may create a lack of cooperation on a worldwide basis in this particular field.

Dr. WATERMAN. Yes; this is a problem of course. Let me tell you the thinking that went on during the discussion of the IGY satellite program. You will recall that when we considered the United States participation in this program we announced that we would make freely available to all nations the reports of the scientific observations we were going to make, the instruments that did it, and we told just how these instruments would report so they could hear the radio signals from the satellites. We told them what wavelength these would be on and how other nations could pick them up.

But we also told them the launching of these vehicles would be under the Department of Defense and this would be a matter that we would not divulge except to the extent that the military were willing to do so.

So the security problem could be the means of getting the space projectile into its orbit, the extent to which this uses military methods which have to be classified.

Beyond that, it seems to me science leaves this well open and furnishes a very convenient ground for cooperation in just the manner we had planned our original IGY operations.

Mr. SISK. To what extent have other nations participating in the IGY made available to us their scientific findings?

Dr. WATERMAN. There has been very good sharing. In fact, this has been a most agreeable surprise, that the nations have worked so cooperatively.

This has been especially true, for example, in places like the Antarctic Continent where all nations communicated on what they are doing and exchanged scientists. This has taken place throughout the whole program and information is already being pooled.

In the satellite programs there is an agreement that the information be pooled, but due to the nature of receiving the information from the satellite; namely, by radio, which is coded, and because the information comes in in different forms, recordings in scientific experiments have to be interpreted.

It takes a long time not so much to decode these signals, but to analyze them and put them in a systematic manner so that people will understand. So, in the case of satellite operations there will be quite a long delay before the information can be put out in intelligent form.

Mr. SISK. The data have to be evaluated?

Dr. WATERMAN. Yes, and put in shape so that it is intelligible.

Mr. SISK. I have one other question, Doctor. There seems to be a great deal of concern among some people in the scientific field, that there has not been the freedom to engage, let us say, in power research and what we might even call scientific dreaming, to some extent.

Along that line I have received some criticism from rather reputable scientists in this country that the NACA has tended to restrict some of the freedom of the scientific minds.

Now, do you agree or disagree with that, Doctor?

Dr. WATERMAN. I can put this in two ways. To the extent that the mission of the NACA is carried out; namely, the development of aerodynamics and flight through the atmosphere, there have been very good in encouraging new ideas, and they have had a number of them. But this is applied research in the direction of assistance to aviation, flight.

In that respect they have had a number of notable achievements showing that they have left their men plenty of latitude to dream with respect to possibilities. They have not gone so much into the basic research side because that has not been their mission, for example basic research underlying power for rockets.

One might say, if one wanted to be overly critical of the Agency, that they had kept their people thinking about basic research and applied research on the job that the Agency had to do and not wandering out beyond the confines of this work into power science. But this is not their job, and I think they are right.

Mr. SISK. I appreciate your answer, Doctor, because that clarifies a little in my mind some of the criticism I have heard regarding the NACA. In fact, it was worded something like this: that in NACA a person ceases to become a slave to apparatus, a slave to a particular machine and a particular program.

I see now as you analyze it the reason why. Of course, they have specifically planned their programs and apparently some of these people think they are confined to rather narrow lines. When they are working on the program they are not free to have the latitude in order to have their minds wander in the full range of scientific possibilities; is that correct?

Dr. WATERMAN. Yes. This is specified in the Executive order that the Chairman mentioned a little while ago, where after saying the National Science Foundation is responsible for what you might call general purpose basic research throughout science, it goes on to say:

> The conduct and support by other Federal agencies of basic research in areas which are closely related to their missions is recognized as important and desirable, especially in response to current national needs, and shall continue.

So basic research which underlies an understanding of their own problems is entirely legitimate and should be encouraged in every way.

It is most important in my opinion that an agency actually do basic research in the areas which help it out in understanding of its mission.

This is the way that the Agency can achieve its objectives more intelligently and plan its developments more intelligently and with more economy.

Not only that, but this gives their scientists a chance to get recognition as scientists which helps the morale of the organization. It makes certain, too, that the problems they are considering get into an area of science which causes a "feedback" of science into the Agency.

Mr. SISK. You feel that the proposed Agency to be created by legislation now pending would create a better climate for that type of basic research, than, for example, a commission for such as the AEC; is that correct, Dr. Waterman?

Dr. WATERMAN. The action I speak of could take place under either system. It is a little hard to decide on this particular point between the two because in one case you have a large Board which can be helpful in suggesting ideas and in the other a Commission which though smaller would serve full time.

At the same time, the advantage of the system with the director lies in more complete authority, not so much in connection with his use of basic research—he should do that with the advice he gets—but because of the quicker decision making and stronger action he can take where necessary.

Mr. SISK. Thank you, Doctor.

The CHAIRMAN. I may have to leave so I will ask a few more questions.

Doctor, on page 6, line 3, the language is used: "scientific community." What do you understand is meant by the use of the words "scientific community," in this bill?

Dr. WATERMAN. My understanding would be that this means the scientists who have for their life's work the advancement of science, as such.

The CHAIRMAN. Confined to the United States, or worldwide?

Dr. WATERMAN. It could be either.

The CHAIRMAN. In other words, it is not confined to the United States in an arrangement for participation by the scientific community and so forth, but it could be worldwide or regional groups of nations?

Dr. WATERMAN. The immediate thing it seems to me would be to consult our own scientific community. This would be the National Science Foundation for the Government, or the National Academy of Sciences as an agency primarily outside the Government, and through these agencies to the scientists of the country who are concerned with the particular problems that arise.

The CHAIRMAN. Your interpretation is that it is not confined just to the scientific community of the United States?

Dr. WATERMAN. No, it could go further. In the first instance it would be this, but certainly the scientists of other countries would also be involved, especially if there turned out to be the possibility of a cooperative program among nations.

The CHAIRMAN. Is this the only function and responsibility of National Science Foundation, to cooperate with other nations through their scientific community?

Dr. WATERMAN. I cannot think of any other International Cooperation function of the NSF in space research at the moment. Certainly if we are to be engaged in cooperative undertakings with other nations, then this new Agency would be the one to cooperate with respect to the space platform and vehicle programs of other nations.

The CHAIRMAN. Let me call your attention to page 2, the declaration of policy, subdivision 4, line 18:

The preservation of the role of the United States as the leader in aeronautical and space science and technology.

What would this agency have to do in order to perform that duty?

Dr. WATERMAN. It should see that the United States maintains competence in the area to the greatest degree possible.

The CHAIRMAN. I can understand that part. I am asking you to tell the committee what would the agency have to do? Would it have to have an international organization? Would it have to have a CIA of its own? Would it have to have knowledge in order to pass on that, assume some responsibility as to determining how far some other nation has gone?

The preservation of the role of the United States as the leader in aeronautical space science and technology.

There is a lot of relativity to that, is there not?

Dr. WATERMAN. There is.

I would like to point out that if we are going to be the leader in this field, then we should get busy and drive hard on all the things we know how to do best.

If we can hear from other nations, the extent to which we can share information will help us to do that.

But we should avoid the situation where we try to find out what some other countries are doing and then try to beat them in that particular feature.

The CHAIRMAN. Sharing information would not necessarily come within (4) of the bill. The preservation of the role of the United States as a leader involves having complete information intelligence, and everything else, does it not?

Dr. WATERMAN. It does to determine whether we are leading, or not.

But if we are to do a job here we just have to get on with it to the utmost of our ability and hope we will come out as leaders. What more can we do?

The CHAIRMAN. I can understand all that, but I am wondering, if this agency is established, just how in terms of practical operation it is going to perform that responsibility.

Dr. WATERMAN. They must see to it that they have the wisest counsel they can get in the determination of their plans, that they have the best scientific advice that this country can offer and the best intelligence on what scientists are doing in other countries.

Other than that, it is an operating function to get on with it in order to succeed.

The CHAIRMAN. Take (6) of the bill;

The cooperation by the United States with other nations and groups of nations,

and so forth. How would you anticipate the new agency would carry out that point?

Dr. WATERMAN. It could do it by working through the basic and applied sciences in other countries where there is opportunity to do this, to discuss mutual problems.

This gets to be a complex topic which I should like to clear up if I can.

Let me answer by saying this is the way science has worked and always has worked, in an interesting combination of competition and cooperation. If two scientists are working on a similar problem, then each one, of course, wants to get out original work and his reputation depends on it.

So he does his utmost to come out with good research before someone else does.

But, at the same time, it must be original. Now, it cannot be original unless he knows what others are doing. So he confers with others.

Since they are in the same position they have to confer with him. So you find scientists comparing notes on what they are doing and at the same time, when they go home, working hard to come out first, but they are doing both. It seems to me the agency can do both.

The CHAIRMAN. They ought to do more than that in order to carry out the responsibilities of (4) and (6).

Where does the State Department come in? Is that not the Department that has the primary jurisdiction over international affairs?

Dr. WATERMAN. They would certainly be involved in any discussion with other nations.

The CHAIRMAN. You would assume in discussing matters of foreign policy that this new agency——

Dr. WATERMAN. Would work through the State Department.

The CHAIRMAN. Yes. I would even go further, that they would look to the State Department for policy.

Dr WATERMAN. Yes, sir; that is quite correct.

The CHAIRMAN. Do you and your associates feel that this bill is broad enough in that respect?

Dr. WATERMAN. It may need spelling out in the bill; I should think it should be clearly understood that any negotiations for cooperation with other countries should be done through the State Department and with their approval.

There is a similar situation with respect to basic science I spoke about.

The CHAIRMAN. It might be well to spell it out.

Dr. WATERMAN. All right.

The CHAIRMAN. Mr. McDonough.

Mr. McDONOUGH. Dr. Waterman, speaking about cooperation with other nations in the exchange of scientific information, the State Department has nothing to do with the exchange of scientific data on medicine or chemistry or engineering with foreign countries; does it?

Dr. WATERMAN. Yes, sir. Recently a special scientist was appointed in the State Department, Dr. Wallace Brode, who reports directly to the Secretary of State and this is in his direct province. He is arranging for the setting up of scientific attachés in various countries.

Mr. McDONOUGH. Is this a new function?

Dr. WATERMAN. Yes.

Mr. McDONOUGH. Heretofore, in years past there has been cooperation with German physicians by United States physicians, and with English, French, and Italian doctors. There was no channeling through the State Department on matters of that kind heretofore; is that true?

Dr. WATERMAN. That is true. There are certain exceptions. There are agricultural attachés, military attachés, but this does establish a home for science in the State Department. We, with other countries are cooperating in the exchange of scientific information and in the matter of scientific programs in different countries to make certain that we can set up an exchange that will be valuable to us here. That is done through the State Department. In this the State Department can assist in the normal exchange you refer to.

Mr. McDONOUGH. Suppose an Italian chemist and an American chemist wanted to collaborate on some subject matter and on some basic research, as you said, to find out what the other fellow was doing in order to be the initiator of a new applied science in certain lines. Would that have to go through the State Department for two private individuals?

Dr. WATERMAN. No, because Government policy is not particularly concerned there. What is done between individual scientists in pure science has always been a matter of direct exchange.

Certainly in most countries the State Department would not have to pass on that. The advantage of the new system would be that the State Department could lend a hand and encourage this.

Mr. McDONOUGH. Of course, there would be a disadvantage to the new system, too. Certain information that a foreign country did not want this country to have would not be forwarded to the State Department, and certain information which we did not want the other country to have the State Department could censor, whereas, heretofore, there has been an exchange in the cultural and scientific arts with foreign countries.

I realize that our security is at stake. Where certain things are essential we may have to protect ourselves.

Dr. WATERMAN. There is no cutoff of free exchange contemplated that I know of. Certainly Dr. Brode would be all for encouraging——

Mr. McDONOUGH. I do not mean they are doing that, but it could be a means to that end.

Now this is the International Geophysical Year and, according to your statement, a resolution was adopted by the Geophysical International in 1954 encouraging this Nation to put a satellite in orbit.

You say the United States and Russia picked up the challenge, and we have satellites in orbit.

I understand they have agreed not to continue the International Geophysical Year.

Dr. WATERMAN. As a program, yes.

Mr. McDONOUGH. Suppose when the year is over Russia declares that any nation that puts a satellite in orbit is doing an overt act because it may be used for reconnaissance and surveillance of Russia What position are we in now? Now this is an open season this year, but when the year is over, the scientific data has been compiled, from here on Russia says this is an overt act, what can we do then?

Dr. WATERMAN. This would become a matter certainly of serious United States policy which would have to be considered carefully by the Government—the State Department and the Department of Defense, and so forth.

Mr. McDONOUGH. Insofar as the military operating launching of the satellites, if this new Agency comes into being, do you think it should be the parent agency for basic research and applied science in

space technology for all branches of the Government that are interested in that?

Dr. WATERMAN. Yes, with emphasis on space exploration.

Mr. McDONOUGH. Would that include the operation of the Minitrack station and the other apparatus we have for tracing and launching satellites?

Dr. WATERMAN. Those are essential for space exploration.

Mr. McDONOUGH. That would mean that an agency would then control Cape Canaveral and the launching stations for satellites?

Dr. WATERMAN Not necessarily the military ones. They could use their own.

Undoubtedly they could use the military sites, by arrangement with the military.

Mr. McDONOUGH. We have no launching areas except Cape Canaveral—the others have to be built. But this Agency should build its own for launching and for scientific purposes?

Dr. WATERMAN. I would expect that is ultimately what would happen, sir.

Mr. McDONOUGH. You can see that this National Space Agency, as the bill provides, would also comprehend the National Science Foundation?

Dr. WATERMAN. Comprehend it?

Mr. McDONOUGH. Yes, it would be the parent agency of all scientific organizations in the United States. Would the National Science Foundation be subsidiary to this Agency?

Mr. WATERMAN. Would the National Science Foundation?

Mr. McDONOUGH. Yes.

Dr. WATERMAN. No, indeed. As I was explaining, I think we still have the responsibility for support of basic research and scientific information in the United States.

Our position would be that where the observations from space platforms concern an area of pure science, then this Agency would look to us to work in cooperation on such programs. They would have their own research with which we in turn would not be particularly concerned, and then there would be other areas of research in which both would be interested.

So this is a matter of cooperation, not a matter of rivalry. We would still have our same area of responsibility, in other words.

Mr. McDONOUGH. If this Agency were established, would the National Science Foundation then have, in your opinion, to launch its satellite for its own scientific investigation?

Dr. WATERMAN. No, the launching of the satellite and the machinery to do it with, is the responsibility of this Agency. It is as if we wanted to make some observations from an airplane, then we would have to hire an airplane from an airplane company, or else go to the Department of Defense and ask if we can use theirs in order to get the observations done.

We would arrange to perform the experiment. The experiment would be our responsibility. The provision of the vehicle to do it would be someone else's.

If we had a scientific experiment we wanted very much to do in pure science, we would go to this Agency and say, "Have you a vehicle that can do this and, if so, we would like to make arrangements to get this done as part of your program."

In most cases they would be interested considerably themselves, but if not, this would become a matter of importance to science and we could claim this.

Mr. McDONOUGH. You spoke about the need for learning more about the effects of cosmic rays on space vehicles and on human beings in space. Have not the satellites we have launched given us some pretty good information on that up to now?

Dr. WATERMAN. Yes, but it has not been fully analyzed. Explorer III has a cosmic-ray counter in it and we have been getting observations from that right along. These observations are going to be reported on Thursday at a meeting of the National Academy of Sciences along with the existing observations of satellites to date.

One interesting thing that has developed in this Explorer III is that the cosmic-ray counter at certain points goes blank. Apparently it is overloaded.

Mr. McDONOUGH. Is there an absence of cosmic rays in that area?

Dr. WATERMAN. It cannot be that because it comes to a peak and then shuts off. The mechanism of the counter is such that it can get blocked in that way.

So something is hitting this with considerable intensity and we want to know very much what it is. Until we analyze this further, we won't know for certain.

Mr. McDONOUGH. From what we know of cosmic rays at the present time, will you briefly elaborate on what danger they present to a human being or to metals we know?

Dr. WATERMAN. Yes. The cosmic rays are essentially nuclei of atoms, the same kind of thing we get in the nuclear accelerators, but a greater variety of atoms than we can use in our nuclear accelerators, the artificial machines, and in general tremendously more intense.

Now I am talking about the ones in outer space. Those hit the earth from every direction. Some come from the sun, but only a minor part. In general they are more intense, these primary rays, than anything we can produce in the laboratory.

So nuclear physics is greatly interested in them as one of the primary particles in its studies. As such they cause all sorts of consequences when they strike other nucleii of atoms.

By studying nucleii that are hit by cosmic rays we can determine something about the way the nucleus behaves. These cosmic rays from outer space are so intense they give us results we cannot get from artificial machines.

By doing this in outer space we get the original, primordial cosmic rays before they hit our atmosphere.

After they hit our atmosphere then they begin to cause all sorts of secondary effects in the atoms of our atmosphere, the nucleii of those.

So by the time they get to the earth they are very complicated; a lot of secondary and other particles are produced like electrons, protons, and neutrons.

In outer space we can study these in virgin territory, you might say.

Mr. McDONOUGH. At what elevation would you say?

Dr. WATERMAN. This would be beyond the atmosphere. If you get out, say, 40 or 50 miles, you would be reasonably free from the effects of the atmosphere.

That is all on the physical science side.

On the damage to life, we know that cosmic rays, if intense, can produce injurious effects. The human race has always been exposed to cosmic rays from the earliest times, but it is only to a very slight extent.

In this room at the present time every one of us is exposed to them. Every cubic inch is exposed to 5 or 6 cosmic rays per minute, coming through.

The human race has always been exposed to those. If they are very intense they can cause the kind of damage that penetrating radiation does, such as from reactors.

Mr. McDONOUGH. Deterioration of tissue?

Dr. WATERMAN. Yes, killing tissue and all that.

Mr. McDONOUGH. Do you get a magnification of cosmic rays in intense sunlight?

Dr. WATERMAN. Not in intense sunlight necessarily unless the sun happens to be emitting these cosmic rays. The sun is not a strong emitter. It is only recently we discovered it emitted them at all. They came from outer space.

Mr. McDONOUGH. It is not a particle, it is a ray of light?

Dr. WATERMAN. The original cosmic rays are particles. When they strike other nucleii they cause fragments of those nucleii to go out which themselves hit other nucleii and along with that produce dangerous waves like gamma waves from radioactive materials, intense X-rays and things of that kind. These are effects that are damaging.

At high altitudes they are much more intense than they are at the surface of the ground. That is why we need to look at them carefully there.

Mr. McDONOUGH. Have we been able to simulate cosmic rays in the laboratory to study their effect on materials?

Dr. WATERMAN. Only the ones that are slowed down, you might say, the slow ones that reach the surface of the earth. The ones with terrific energies we cannot come anywhere near simulating.

Our biggest atom smasher is now producing 6 billion equivalent volts. It is shooting electrified particles as though they were shot by a 6-billion-volt machine. That is the most we have been able to do in the laboratory.

Now, the cosmic rays it has been known for some time, do more than that. The number is so much bigger it is almost inconceivable.

Mr. McDONOUGH. In other words, a cosmic ray is a tremendous force that we must know more about?

Dr. WATERMAN. That is right. They are tiny particles and there are not many of them, but we need badly to know more about them.

Mr. McDONOUGH. In other words, a cosmic ray is a tremendous force we know very little about?

Dr. WATERMAN. Yes.

Mr. McDONOUGH. And we want to learn more about it?

Dr. WATERMAN. Yes.

Mr. McDONOUGH. The next important thing for exploration is the magnetic force of the earth in outer space. How far have we gone in our knowledge of that in applied science?

Dr. WATERMAN. Well, both in pure and applied. Of course, the knowledge of the magnetic field of the earth is important in the magnetic compass that we have used over the years.

The trouble with it is that it does not give true north and it varies according to where you are because the earth's magnetic poles are not where the geographic poles are.

Also, it varies in many ways, including a daily variation.

Mr. McDONOUGH. Have we been able to discover the magnetic force of the earth from the satellites we have released?

Dr. WATERMAN. Not directly because we have not yet got our satellite up that will make these magnetic observations.

Mr. McDONOUGH. None of the satellites we have put up have had it?

Dr. WATERMAN. No, what we badly need to know is what the magnetic field of the earth is like away from the earth because it is there the sun has its biggest influence on the earth and that might be shown first in the magnetic field out there.

Mr. McDONOUGH. That is quite a distance away?

Dr. WATERMAN. Yes. We don't know such matters as whether the magnetic field is influenced by streams of electrified particles going around the earth. If such were the case, they would produce a magnetic field on the earth. We would very much like to know if this is part of the picture this stream of electrified particles going around like a big current, producing the magnetic field we see on the earth.

Mr. McDONOUGH. Do we know anything about the magnetic field of our closer planets? Is there such a thing around the moon, or Mars?

Dr. WATERMAN. We would like very much to know whether the moon has a magnetic field. We have no idea really. We suspect it probably has a weak one, but we would very much like to know.

Now, the sun does. Also the particles coming from the sun produce changes in our own magnetic field. When we get showers of electrons from the sun we know this upsets the compass.

Mr. McDONOUGH. This probably has an effect on our thundershowers.

Dr. WATERMAN. It may have.

Mr. McDONOUGH. Thank you very much.

Mr. BROOKS (presiding). Mr. Keating.

Mr. KEATING. I want to ask you a couple of questions about outer space. That is a pretty hard concept for a bunch of Congressmen to get.

What kind of scientist are you?

Dr. WATERMAN. A physicist.

Mr. KEATING. You are the kind that ought to know the most about outer space. If I get up there, or anything else gets up there, in order to stay there it has to keep in orbit and it has to keep moving around at least 18,000 miles an hour?

Dr. WATERMAN. It has to keep that speed if it is at the height of our present satellites. It does not have to go that fast if it is out further.

Mr. KEATING. Even up 100,000 miles it would have to go pretty fast?

Dr. WATERMAN. Yes, indeed.

Mr. KEATING. Suppose I am going around up there and I throw a pan of water out. Does that water go around the same rate I am going?

Dr. WATERMAN. If you threw a pan of water out from a satellite, if the water could stay liquid it would go around with you.

Mr. KEATING. Suppose I toss a ball out, would that go around with me?

Dr. WATERMAN. Yes, but of course, the water would evaporate instantly.

Mr. KEATING. Anything that is detached from anything else that is going around up there, will go around at the same speed?

Dr. WATERMAN. Yes, you cannot drop anything from a satellite. If you put it out of the window, if you could, it would just go around with you.

Mr. MCDONOUGH. Which you could not do?

Dr. WATERMAN. Not without some mechanical trap-door arrangement to do it.

Mr. KEATING. You cannot put anything below you or above you without some propulsion apparatus?

Dr. WATERMAN. That is correct.

Mr. KEATING. If you had a propulsion apparatus you could do that.

Dr. WATERMAN. You would have to either push it or have a device like a little rocket which will give it speed.

The only way that we know clearly for propelling anything in outer space is by the rocket principle; that is, by sending something in one direction which makes you go in the other direction.

Mr. KEATING. Now, what is the distance to the nearest star?

Dr. WATERMAN. The nearest fixed star is about 4 light-years which means that light traveling 186,000 miles a second would take 4 years to get there.

Mr. KEATING. Then it is a figure of miles from here that is almost impossible to comprehend?

Dr. WATERMAN. That is exactly right.

Mr. KEATING. Then is that why we talk all the time about interplanetary travel?

Dr. WATERMAN. The planets are distinguished from the stars.

Mr. KEATING. How near to the sun are the planets?

Dr. WATERMAN. We are 92 million miles from the sun.

Mr. KEATING. That is not the nearest planet to the sun?

Dr. WATERMAN. No; the nearest is Mercury.

Mr. KEATING. How far is that?

Dr. WATERMAN. About one-third—36 million miles.

Mr. KEATING. It is going to take us, according to the story we got, 4½ days, roughly, to go 240,000 miles to the moon.

Dr. WATERMAN. This depends on the speed, of course. The moon is only 240,000 miles away. You might be able to reach that in a matter of hours, like 8 or 10 hours.

Mr. KEATING. The figure I was given by the Army is 4½ days.

Dr. WATERMAN. This depends on how fast you want to travel.

Mr. KEATING. It is fast enough for me.

Dr. WATERMAN. If one is trying to go to the moon and by it out into space, then you could go a lot faster. But if you want to go and land on the moon, then you don't want to go too fast because you want to simplify the problem of landing softly. So that would take you longer.

Mr. KEATING. Does this talk about interplanetary travel presuppose that we are going at much greater speeds than 240,000 miles an hour.

Dr. WATERMAN. We don't know. Of course, we would like to be able to, and with present techniques we could step this up considerably, I don't know just how far. When you do, of course, you complicate the problem of slowing up at the other end if you want to land.

But the fact is that it takes a long time to get to another planet, really a long time, a matter of a year or so perhaps, by the speeds we are talking about.

Mr. KEATING. Let me ask you this question: You talked about light-years. You said that we would never be doing this traveling to these stars because they are many millions of light-years away?

Dr. WATERMAN. In the case of most of the galaxies that is true.

Mr. KEATING. We had a fellow that said if you go 95 percent of the speed of light, or the speed of light, time does not count. Why can't you go up there and spend 10 million years and come back here and be the same age you are today?

Dr. WATERMAN. Perhaps you can, but by the same token time here would be 10 million years hence. Who knows if, when man got back, we would still be here or anything like us. Maybe the earth wouldn't exist.

Mr. KEATING. It is a theoretical matter. If you got going as fast as the speed of light you could go up there and stay almost forever and come back here and you would be no older than you are now; is that right?

Dr. WATERMAN. There are two theories about this. The plain fact is, as you were saying, we believe that we cannot go faster than the velocity of light.

We also know that to try to go anywhere near the velocity of light takes a prodigious effort. The closer you get to the velocity of light the harder it is to go any faster. Your mass increases and you have to be pushed terrifically to do it. Nobody has solved whether we can stand that kind of acceleration. If one could get to the velocity of light time apparently would stand still.

But I have not heard the specialists say that they are sure whether if you did this then time would stand still and when you came back you would be "behind time" in this sense. There is a school of thought which says "No, this cannot be right; nature would not act that way. When you come back you would join on to life as you had it before."

But the experts have not decided this.

Mr. KEATING. When are they going to decide that?

Dr. WATERMAN. We have had no good opportunity to make experiments on that. It would be a hard thing to work out.

Mr. KEATING. Of course, if you go up there and stand still for a million years and come back here, it is no good unless you take your friends with you.

Dr. WATERMAN. I expect not.

Mr. KEATING. Well, it is fascinating to me.

Dr. WATERMAN. Yes; it is to anyone.

Mr. KEATING. And we appreciate having someone here to clear up our minds, or, at least, cause greater confusion.

Thank you.

Mr. BROOKS. Mr. Fulton.

Mr. FULTON. Your agency has been participating in the International Geophysical Year and has been doing a good job. We want to compliment you.

Would you put a statement in the record of the history of the participation of your agency in the International Geophysical Year?

Dr. WATERMAN. I shall be very glad to.

Mr. FULTON. Likewise the calendar of events that you intend to complete during the year?

Dr. WATERMAN. Fine.

Mr. FULTON. Would you also tell us on the committee of this meeting of the National Academy of Science, where the three scientists are going to give out statements on the United States participation with our Vanguard and Explorer satellites? Can you tell us where that is and is it going to be open to the public.

I am really asking so that the public will know.

Dr. WATERMAN. It is in the National Academy of Sciences in their great hall.

Mr. FULTON. It is open to the public?

Dr. WATERMAN. I believe so.

Mr. FULTON. I know it is, and I am trying to make it public. Are those statements that are being prepared for this Academy of Science on Thursday available now?

Dr. WATERMAN. Some have been already published. Perhaps you will recall there was an article in Science recently, about the first of February, giving a summary of the highlights of the International Geophysical Year to date.

Quite a lot is in that.

Mr. FULTON. Could we put that summary in the record at this point, if you would provide us with that?

Dr. WATERMAN. Yes, indeed

(The summary mentioned above is as follows:)

[Reprinted from Science, January 17, 1958, vol. 127, No 3290, pp. 115-128]

INTERNATIONAL GEOPHYSICAL YEAR—A REPORT ON THE UNITED STATES PROGRAM

Hugh Odishaw [1]

The International Geophysical Year began on July 1 and will continue through all of 1958. This article presents a brief account of some of the activities during the first 5 months, July 1 to November 30, 1957.

Although this account is primarily concerned with the United States program, some references are made to the activities of other participating countries. It should be noted that 67 countries are cooperating in this study of the earth and its cosmic environs; the types of work described here are also being conducted by other national IGY groups. For the convenience the IGY investigations may be classified under three categories: (i) the physics of the upper atmosphere, (ii) the earth's heat and water regimen, and (iii) the earth's structure and interior. Subjects in the first category include solar activity, aurora and airglow, cosmic rats, ionospheric physics, and geomagnetism. This category also includes rockets and satellites, tools for sending instruments into the upper atmosphere. Subjects in the second category include meteorology, oceanography, and glaciology, and those in the third include seismology, gravity, and determinations of longitude and latitude.

The following sections report briefly the activities in each of the fields in each of the three categories. A final section outlines aspects of the collection and interchange of data in the IGY program.

PHYSICS OF THE UPPER ATMOSPHERE

Solar activity.—As particles radiated from the major solar flare of June 28, 1957, began to arrive at the earth, 2 days later, a storm wracked the earth's magnetic field. The ionosphere—the layer of electrically charged gas between

[1] The author is executive director of the U S National Committee for the International Geophysical Year of the National Academy of Sciences, Washington, D. C.

about 40 and 200 miles above the earth's surface—was torn by electrical disturbances; long-range radio communication was blacked out for a long period of time. The flare was first observed at the Krasnaya Pakhra Observatory in the Soviet Union. Immediately a message was flashed to the World Warning Agency operated for the IGY by the National Bureau of Standards at Fort Belvoir, which declared a state of alert beginning at 1600 universal time, June 28. Alerts are declared when there is probability of solar disturbances. When the possibility is high that terrestrial disturbances will also occur, special world intervals are promulgated, calling for an increased number of measurements of solar-terrestrial phenomena. The first such interval in the IGY was declared June 29, to commence at 0001 universal time on June 30. Throughout the world observations of the sun were intensified, and balloons and instrumented rockets were sent up by many nations to observe the increased ultraviolet and X-radiation and to monitor cosmic-ray intensity. Observations and measurements were speeded up to record more carefully and fully the northern and southern lights, to measure disturbances in the earth's magnetic field, and to probe the ionosphere.

During periods of maximum solar activity radio communications are often interrupted by fadeouts or blackout, particularly after the occurrence of a flare on the sun. On these occasions pulses transmitted to the ionosphere by ionospheric sounders are not reflected as usual but are absorbed. It had long been thought, but not heretofore conclusively established, that this absorption must be caused by increased ionization in the lower atmosphere. On July 4, radio signals received from a rocket fired up through the ionosphere demonstrated the presence of an additional layer of ionization extending for about 12 miles below the normal lowest point. Even more remarkably, the rocket data showed that the normal ion distribution throughout the ionosphere above the D, or lowest, layer, seemed to remain undisturbed during the blackout In another recent IGY rocket experiment, it was ascertained that the additional electron layer was caused by solar X-ray emission associated with the occurrence of solar flares.

Rockets are only one means of studying solar phenomena. Solar astronomers have organized themselves in a worldwide solar patrol, keeping watch on the sun all over the world throughout the 24 hours of the day. Solar observation stations are operated by 33 countries; of 126 stations all over the world, 14 are operated by the United States, not including rocket-firing sites.

By observing the sun through special filters which limit transmission to the light of certain radiations of hydrogen or calcium, astronomers look for the giant eruptions or flares on the sun which are responsible for radio blackouts, auroras, and magnetic storms. Very narrow band filters are used, since the flares would otherwise be invisible against the bright surface of the sun.

Special instruments are also in use to photograph the chromosphere of the sun, a shell of very incandescent gas just above the sun's surface, and the corona, an envelope of gas that may extend all the way to the earth. The chromosphere and corona are invisible except when an eclipse shuts off the light of the disc, or when the sun is artifically eclipsed in a special telescope called the coronagraph.. Using the coronagraph, scientists are able to photograph solar flares at the edge of the sun; these flares sometimes shoot out into space for several hundred thousand miles at very high speeds.

At Mount Wilson Observatory in California, measurements are being made of the magnetic field of the sun at its surface It has already been found that magnetic fields at the sun's surface may be very high, as much as 8,000 times that of the earth's field at the equator. These magnetic fields are thought to play a very important role in disturbances and storms on the sun's surface as well as in sunspots.

Geomagnetism.—Thirty countries throughout the world are operating 129 magnetic observatories, from the North to the South Pole and in almost every region of the earth's surface; 31 of these stations are part of the United States program in geomagnetism.

Newly established United States IGY geomagnetic stations are in operation in the Arctic, in the Pacific Ocean, in continental United States, and in South America with the cooperation of IGY scientists in Peru. Certain of these stations are set up in chains, with carefully planned spacing, to study in detail the magnetic storms which occur during great solar disturbances It has been suggested, but not before positively established, that the magnetic effects we observe on earth during magnetic storms may be due to great electric currents, of perhaps several hundred thousand amperes, flowing around the earth high in the atmosphere. Two of these currents are believed to circle the North and South magnetic poles, while the third circles the earth at the geomagnetic equator. This theory is being examined.

The stations in South America and in the Pacific Ocean—at Guam and Koror in the western Pacific and at Jarvis, Palmyra, and Fanning Islands in the eastern Pacific—were established especially to study the existence of the so-called electrojet. The electrojet is believed to be the equatorial electric current, but narrowed down into a neck of limited horizontal dimensions with consequent increased current density and intensified activity at local noon. The United States Coast and Geodetic Survey, which operates many of the magnetic observatories established by the United States, reports tentative confirmation of this phenomenon. Initial data from Koror reveal the existence of the equatorial electrojet and its rather limited horizontal extent.

Aurora and airglow.—A worldwide comprehensive auroral observation program in 49 countries is under way for the first time during the IGY. Many of these 49 countries are in low latitudes where auroras are seldom seen. Nevertheless, in all of them, auroral reporters have been appointed to collect reports of visual observations in the event that a very great aurora should occur. A number of such auroras have been reported in the last century, but these events of great scientific importance have usually been inadequately described. One hundred and forty-two camera and instrumental auroral observation stations, as well as extensive amateur visual observing programs, have been organized in 17 countries.

The 39 stations and hundreds of amateurs participating in the United States program have already had much to observe. The fact that the IGY was scheduled for a period of expected maximum solar activity has greatly enhanced the value of the program, for already three of the largest solar flares (class 3+) have resulted in extensive auroral displays visible as far south as Havana, Cuba. Synoptic maps have been prepared depicting all auroras observed and reported from the United States during the months of July and August. This is the first time that such a complete description of auroral data has been assembled for the use of geophysicists studying auroral and such related phenomena as ionospheric and geomagnetic effects.

English scientists at the University of Manchester have reported that simultaneous radar observations indicate that auroras occur simultaneously in the Northern and Southern Hemispheres, a condition long believed to be true by scientists, but not previously established Additional polar radio data which provide further evidence on this question have been obtained in the United States program.

The systematic reduction of the variations in the intensity of the night airglow is proceeding. Charts of the patchiness and movement of night sky luminosity resulting from oxygen emissions are being produced on a routine basis from IGY observations.

Ionospheric physics.—One of the major problems in ionospheric physics is predicting the future state of the ionosphere. If we can determine the condition of the ionosphere in advance, we can do much to develop more reliable radio communications, with direct rewards in safer travel in the air and at sea. Forty-one nations are conducting studies of the ionosphere during the IGY, and a worldwide network of 253 ionospheric observing stations has been established. Seventy-one of these stations are sponsored by the United States. The data obtained by the network will provide a worldwide picture of the behavior of the ionosphere.

New information about the farthest reaches of the atmosphere is being obtained from the study of whistlers—whistlelike sounds which can be detected at very low radio frequencies. These signals, originating in lightning flashes as the surface of the earth, swing out thousands of miles along the earth's lines of magnetic force before they return to the opposite polar hemisphere. Early IGY experiments demonstrated that the ion density and molecular concentration along the whistler path at altitudes of as much as twice the earth's radius must be much greater than formerly anticipated. Indeed, there seems to be confirmation for the theory that the earth's atmosphere extends far beyond the level where it had been previously thought to end and that there may be a very tenuous atmosphere—the sun's corona— filling all the space between the earth and the sun.

Other records of previously unexplained radio noise at very low frequencies have stimulated the hypothesis that solar particles arriving in the very high atmosphere transfer energy to very low frequency radio waves there. According to this hypothesis, the radio signals thus amplified are the very low frequency radio emissions observed at ground level. Data now being gathered will throw further light on this hypothesis, which is based on the traveling wave tube principle noted by Roger Gallet.

Ionospheric characteristics are deduced from the analysis of echoes arising from the reflection of radio pulses transmitted to the ionosphere at vertical

incidence. Since the IGY began there have been several major solar events that caused disruption of long-range, shortwave radio communications which depend upon reflections from the ionosphere. For the first time, a synoptic picture has been obtained of the growth and decay, station by station, of such fadeouts.

The principal regular variation in the ionosphere is the diurnal one. Ionization density increases during the day when the sun is present and decreases at night. What would happen to the ionosphere during long absences of solar radiation and the nature of any diurnal variation that might occur during such periods have been subjects of speculation. Only at or near the geographical poles can these questions be examined, and the South Pole affords the best platform for an observatory. Investigations during the last year at the United States South Pole Station have yielded interesting results: In spite of the absence of the sun, the electron concentration seems to remain very high throughout the polar night; moreover, there is a diurnal variation that can only, it appears, be associated with geomagnetic activity. The evidence so far obtained suggests that ionospheric behavior in the two polar regions is essentially the same. Analysis of these observations may appreciably alter our concepts of the ionization and recombination processes in the atmosphere.

Cosmic rays.—Cosmic rays are electrically charged particles which bombard the earth continuously and from every direction. Although their existence has been known for 50 years, their source and precise nature remain uncertain. In particular, the source of these particles is 1 of the major questions in astrophysics, and the answer is 1 of major importance understanding the cosmos from which the rays take their name These particles, consisting largely of nuclei and having energies ranging from 10^8 to 10^{19} electron volts, are influenced by the earth's magnetic field. Low-energy particles are deflected toward the vicinity of the two geomagnetic poles, and only the more energetic ones penetrate at the middle latitudes.

During the IGY, the scientists of 31 nations are studying cosmic rays at 195 stations; neutron monitors and meson telescopes, cloud and ionization chambers, special photographic emulsions, and window Geiger counters are being used. Rockets and balloons, as well as earth satellites, are important tools for observing these rays. Typical of international cooperation during the IGY is the Swedish-Canadian-American cosmic ray experiment carried out aboard the Swedish merchant ship *M/S Lommaren,* sailing between Sweden and the Union of South Africa.

Investigations at the 20 United States cosmic ray stations have already provided interesting results. The work of scientists from the University of Chicago has shown that the location of the line where the cosmic ray intensity is at a minimum—the cosmic ray equator—deviates systematically from the geomagnetic equator. The experiments leading to this result began in 1954–55 when a neutron pile detector was installed aboard the U. S. S. *Atka,* which conducted a reconnaissance of the Antarctic prior to the establishment of IGY stations in following years. Measurements were made on the trip down to and around Antarctica and back; these measurements were repeated aboard the U. S. S. *Arneb* during the 1955–56 and 1956–57 seasons in Antarctica and were supplemented by aircraft flights in a zigzag pattern around the geographical equator, in October 1956. These studies showed a 40° to 45° westward shift of the inclined cosmic-ray equator with respect to the magnetic equator. J. A. Simpson suggests that this warping may well indicate the presence of important magnetic fields, probably of extraterrestrial origin, which alter the trajectories of the incoming primary cosmic ray particles.

Preliminary balloon flights in and near Minnesota with balloons that carry ionization chambers have shown that, at constant altitude, there is a strong latitude effect. This effect is so strong that changes in latitude of as little as 7 miles can be detected by cosmic ray measurements. Other balloon experiments, at Fort Churchill and Thule, have shown that cosmic rays of lower energy (less than about 2 Bev) have essentially disappeared during the present period of high solar activity, with ionization at high altitudes down to half the value it had in 1954 or 1955.

Perhaps one of the most interesting observations made in the course of IGY cosmic ray experiments was that of relatively soft radiation in the high atmosphere, associated with primary auroral radiations. Rocket and balloon flights have led to the positive identification of the soft radiation: it is X-radiation in the range between 10^4 and 10^6 electron volts. There appears to be good correlation between the presence of such radiation and solar, magnetic, and auroral activity. The effect is probably a secondary one; it is believed that incoming auroral particles create the X-rays by bombardment of atomospheric particles.

Rockets and satellites.—Rockets provide 1 of the 2 important ways of directly measuring phenomena and processes in the upper atomosphere. Rockets are, moreover, unique in that they permit studies of the altitude-dependence of various quantities and events—for example, temperature, pressure, density, and composition. Seven nations are engaged in rocket programs: Australia, Canada, France, Great Britain, Japan, the United States, and the U. S. S. R.

Some 200 rockets are involved in the United States rocket effort. Firings are underway in the Arctic, Antarctic, Pacific, and continental areas. A major facility at Fort Churchill, Manitoba, within the north auroral zone, was constructed in cooperation with Canada, and a joint Canadian-United States program is underway.

There were 29 rockets fired in the pre-IGY test period. These included Aerobees, Rockoons and Nike-Cajuns. Firings took place at the newly erected facilities at Fort Churchill as well as at White Sands (N. Mex.) and Guam, and from shipboard off the California coast and in the North Atlantic These firings were successful, and the preliminary information gained was of considerable value in the final detailed planning of the schedules for firings during the IGY period.

The United States IGY program in rocketry actually began on July 5, 1956, at Wallop's Island, Va., when the first IGY test rocket was fired successfully. To date, 81 rockets have been fired during the IGY. Included have been those in programs conducted at Fort Churchill (9 Aerobees, 5 Nike-Cajuns); White Sands (2 Nike-Cajuns); Point Mugu, San Nicolas Island, Calif. (13 Nike-Deacons), a shipborne operation in the Arctic (18 Rockoons); and a shipborne operation in Pacific and Antarctic waters which was concluded in mid-November (36 Rockoons). The following are some preliminary findings:

(1) A firing at Fort Churchill indicated that the first atmospheric temperature maximum occurred at an altitude of about 60 kilometers. Normally this maximum is found below 50 kilometers at lower latitudes, indicating that, at northern latitudes, the rise is more gradual. (Temperatures decrease up to the stratosphere, rise during the next 20 to 30 kilometers, decrease through the next 30 kilometers, and then rise again.)

(2) A rocket, instrumented for ionospheric studies, was sent through a polar blackout for the first time. Data were obtained which indicated that a very dense D-region exists at a significantly lower altitude, and with a much greater density, than is found at lower latitudes.

(3) A firing at Fort Churchill during the summer of 1957 measured electron distribution in the ionosphere up to an altitude of 250 kilometers during a polar blackout. The results of this experiment confirmed theories that the D-region of the ionosphere is primarily responsible for radio blackouts.

(4) During a series of firings with Aerobees and Nike-Cajuns instrumented for studies of pressure, temperature, and density, it was determined that the distribution of pressure and temperature in the atmosphere at high latitudes is very different from what it is at lower latitudes. Many of these rockets attained altitudes greater than 200 kilometers, and thus the first density measurements made at high latitudes were recorded. Launchings were made during both summer and winter, day and night. The resulting data indicate that the density of the high atmosphere is under strong solar control. There appear to be a latitude effect, a seasonal effect, and a strong diurnal effect; none of these effects appear at lower altitudes at Fort Churchill or lower latitudes.

(5) An experiment with a mass spectrometer at Fort Churchill appears to confirm the belief that diffusive separation of gases under gravity is present above 100 kilometers at that latitude. Below this point the gases in the atmosphere appear to be well mixed.

(6) During July and August 1957, the DAN rocket flare patrol program took place at Point Mugu, Calif. This program was primarily directed toward determining the radiation source of the fadeouts resulting from flares observed on the disk of the sun For the first time, measurements were made of X-ray and ultraviolet bursts from the sun during a solar flare. These data will help in explaining radio blackouts, which are present during periods of unusually high degree of ionization, and which are closely associated with solar flares.

(7) During the shipboard firings in the Arctic, an excellent survey was made for the first time of auroral particles and their association with actual aurorae. Also conducted for the first time at high latitudes were magnetic field measurements.

Satellites represent an extension of rocketry useful in probing the high atmosphere. Satellites provide means to secure data on the variation of phenomena with time and over a vast expanse of space. Two nations are engaged in satel-

lite-launching programs: the U. S. S. R. and the United States. Many nations are cooperating in tracking and ground-based observations. In the United States program, precision radio and optical stations have been established not only in the United States but in 13 other countries whose scientists are cooperating closely with the United States scientists.

The U. S. S. R. launched its first satellite on October 4, 1957. This satellite, a sphere nearly 23 inches in diameter and weighing about 184 pounds carried transmitters broadcasting on frequencies of 20 and 40 megacycles per second.

The second Soviet satellite was launched on November 3. Weighing about 1,120 pounds, the last rocket stage was reported to carry 2 transmitters (20 and 40 megacycles), a dog, and instruments to measure satellite temperatures, ultraviolet light, X-rays, and cosmic rays. The initial period of the second satellite's revolution was 103.7 minutes, with an apogee of approximately 1,056 miles and perigee of about 150 miles.

The United States program is proceeding according to schedule. The Navy has responsibility for the rocket system and launching in the Vanguard series; the Army, for the Jupiter-C series. The IGY Committee of the National Academy of Sciences is responsible for the scientific aspects for both the internal experiments and the radio and optical observation programs. Two types of satellites have been designed: test spheres for use during the test period for the Vanguard rocket system and equipment-laden satellites for use thereafter for both the Vanguard and Jupiter-C vehicles.

The test spheres are 6.4 inches in diameter and weight 4 pounds. They have six 12-inch antennae and 6 solar cells mounted on the skin. These spheres are designed primarily to transmit signals for radio tracking purposes; they carry 2 separate transmitter systems operating on frequencies of approximately 108 megacycles. One is battery-powered while the other is powered by the 6 solar cells, affording the prospect of indefinite transmitter life.

The IGY equipment-laden satellites have 3 main configurations. All but 2 are 20-inch spheres constructed primarily of magnesium, weighing 21.5 pounds, and equipped with four 29-inch antennae. Of the other satellites, 1 is a sphere approximately 13 inches in diameter, with a protruding cylinder approximately 13 inches long and 2.5 inches in diameter; this satellite will be accompanied by an inflatable sphere, 30 inches in diameter and weighing less than 0.7 of a pound, which will be ejected from the carrier rocket at the same time as the satellite is released. The last configuration, a cylinder to be launched in the Army vehicle (Jupiter-C), is of approximately the same weight as the spherical satellites to be launched in the Navy Vanguard rocket.

Equipment carried by these satellites will include instruments to measure the intensity of the solar hydrogen Lyman alpha line; temperatures of the satellite's surface and interior; meteoric erosion, flux, and penetration, geographical, temporal, and altitudinal variations of primary cosmic ray intensity; total magnetic field at altitudes above the more densely ionized regions of the upper atmosphere, air drag; the geographical distribution of the energy received by and radiated from the earth; and the changing patterns of the cloud cover of the earth.

The satellites will be located and data will be obtained from them by means of radio, precision camera, and visual observations, The precision radio tracking system is known as Minitrack; it was developed by and is operated under the supervision of the Naval Research Laboratory. There are 10 Minitrack stations, most of them along the 75th meridian west

The 12 precision optical tracking stations, using Baker-Nunn Schmidt-type cameras, are under the supervision of the Smithsonian Astrophysical Observatory. They are located in 1 longitudinal and 2 latitudinal belts (75th meridian west and 30° to 40° north and south).

There are three programs based on amateur participation in satellite tracking which are designed to supplement precision tracking efforts. The first, for volunteer visual observation teams, is being administered by the Smithsonian Astrophysical Observatory and has been named Moonwatch. Over 100 Moonwatch teams, located both in the United States and abroad, have been registered and are in operation

A similar program, called Moonbeam, has also been established to coordinate the participation of radio amateurs and other volunteer groups having the capability to record telemetry and radio position data. Employing Minitrack II, developed by the Naval Research Laboratory, and Microlock, developed by the Jet Propulsion Laboratory of California Institute of Technology, these volunteer groups supplement the primary Minitrack stations in tracking the satellite and should also provide valuable scientific data.

25973—58——64

The third volunteer tracking program is called Phototrack; it was organized under the supervision of the Society of Photographic Scientists and Engineers. Participants in this program use standard cameras of good quality to photograph the satellite against a fixed background of stars of known positions.

EARTH'S HEAT AND WATER REGIMEN

Meteorology.—Almost all of the energy that the earth receives comes from the sun. This energy evaporates water from the oceans, lakes, and rivers; heats the ground, which in turn heats the air above it; and in general supplies all the energy which drives the winds of the atmosphere.

In the equatorial regions there is more energy received from the sun than is lost back to space; in the polar regions the reverse is true. Since we know that, on the average, considering a year's time, the earth as a whole does not heat up or cool off appreciably, the excess energy gained in the Tropics must be balanced by the loss of energy in the polar regions. The flow of energy between the tropics and the poles is part of the driving force of the atmospheric circulation. A very important factor in the general circulation also is the rotation of the earth. As is well known, the speed at the surface, due to the daily rotation of the earth, is greatest at the equator, which is farthest away from the axis of rotation, and least in the polar regions, becoming zero at the pole itself.

In order to study the winds and circulation of the atmosphere during the IGY, meteorologists of nearly every participating country have intensified their efforts at setting up new stations in hitherto uncovered areas and are making every attempt to send meteorological balloons as high into the atmosphere as possible to measure temperature, humidity, and winds; all countries are collecting meteorological data. In cooperation with the Canadian Weather Bureau, the United States Weather Bureau is operating some key stations in the Far North, supplementing its complex of stations in Alaska and the United States. In cooperation with scientists and weather bureaus of the various South American countries, five new complete weather observatories are now in operation in Chile, Peru, and Ecuador. These five stations are important in a chain of stations reaching from the North Pole, where the U. S. S. R. maintains a station, through Canada, eastern United States, the Caribbean Sea, western South America through Antarctica, and finally to the South Pole, where United States scientists have established a complete scientific observatory.

In addition to this chain of stations, 12 nations have cooperated in locating more than 50 scientific observatories in the vast unknown continent of Antarctica. For the first time, synoptic meteorological charts of this area are being drawn on a daily basis. Weather forecasting has already been markedly improved in the Southern Hemisphere. Aside from the forecasting and synoptic aspect, the scientific value of the observations in Antarctica are potentially of great value in understanding the atmospheric circulation and its relation to solar radiation and topography.

The Antarctic is the coldest place on earth. The continent itself is elevated and mountainous, the South Pole being almost 10,000 feet above sea level. Byrd Station, in the interior, has reported temperatures of about 100° below zero (F.), and recently the South Pole Station reported an even lower temperature, 102.1° below zero.

In the Antarctic meteorology program, large neoprene balloons have been sent to altitudes of over 80,000 feet, and the average is about 60,000 feet. Meteorological balloons sent up at 112 non-Antarctic United States stations are reaching altitudes ranging from 85,000 to 107,000 feet, carrying instruments to radio back to the ground the temperature and humidity.

In addition to these broad-scale programs, several specialized programs are underway, and preliminary results have been received. For example, there is in Little America an instrument which measures the minute quantity of ozone in the air at the ground level. Ozone mainly occurs in a layerlike region about 15 miles high in the earth's atmosphere. Some ozone diffuses to the ground or is formed at lower levels by ultraviolet light. It has been noticed that, at Little America, there is about 25 percent more ozone at the ground than there is in New Mexico. Although ozone is a minor constituent of the atmosphere, it is thought to play an important role in the circulation of the high atmosphere, because of the energy it can absorb and release.

Another minor constituent of the atmosphere which may play a major role in climatic changes is carbon dioxide. This compound is present in the atmosphere in amounts of about 350 parts per million. It absorbs infrared or heat radiation and may act like a trap for such radiation, much as glass does in a greenhouse,

and it may play a very important role in the heat balance of the atmosphere. Our industrial civilization burns tremendous quantities of fossil fuel each year, pouring millions of tons of carbon dioxide into the atmosphere. Most of this is absorbed by plant life and by the waters of the oceans, but there is the possibility that eventually the carbon dioxide content of the atmosphere will rise enough to affect the world's climate. At United States stations and aboard ships, there are seven instruments in use monitoring the content of carbon dioxide in the atmosphere, and scientists are collecting thousands of air samples for later analysis. It has been found already that the concentration of carbon dioxide in the Antarctic is about what it is over the rest of the world away from immediate industrial contamination.

The United States National Committee for the International Geophysical Year was designated by the Comité Spécial de l'Année Géophysique to establish and maintain a Weather Central at the Little America Station to collect and disseminate Southern Hemisphere weather information, particularly for the Antarctic region. The basic program at Weather Central involves the reception and recording of weather data from many contributing sources; preparation and analysis of meteorological charts, maps, graphs, and cross sections—mostly synoptic; and broadcasting of current weather information and analyses for use in forecasting by stations throughout Antarctica and the remainder of the Southern Hemisphere.

The Weather Central staff consists of United States meteorologists together with meteorologists assigned, in turn, by other nations participating in the Antarctic program.

Preliminary reports indicate that significant improvements in the weather forecasts of Southern Hemisphere countries have been made since data from the Antarctic Weather Central became available.

Glaciology.—United State glaciologists are encamped on glaciers and ice fields in Greenland, on the frozen Arctic Ocean, in the mountains of Alaska, on a small glacier in the State of Washington, and on the ice shelves and the great ice sheet of Antarctica, in a broad program designed to map not only the extent of the glaciers and ice but also to understand their flow and their relation to and effect on the local climate. Twenty-seven other countries are also making observations covering all the known ice areas of the world, including glaciers on the equator—at Mount Kilimanjaro and Mount Kenya in eastern Africa.

Technical advances and discoveries have already been made in the two greatest reservoirs of ice in the world, Greenland and Antarctica. In Greenland, scientists of the United States Army's Snow Ice and Permafrost Research Establishment have perfected techniques for drilling deep holes in the ice with hollow drills, much as an oil well is drilled, to obtain a core of ice. The first hole was drilled in Greenland in 1956 and reached a depth of over 1,000 feet. The second hole was successfully drilled in 1957 in Greenland, and a similar operation is now under way in the Antarctic in Marie Byrd Land.

The recent boring in the ice of Greenland reached a depth of 1,438 feet. A complete series of cores 4 inches in diameter were obtained from the first 1,040 feet. Below this depth, recovery of the core is difficult because the release of strains as the ice is drilled causes the ice to shatter. Dissolved gas, which is under great pressure in the ice at these depths, also causes trouble because it bursts through pockets in the ice, increasing the amount of shattering. However, a core was obtained from 1,200 to 1,220 feet, and another from 1,320 to 1,338 feet. These cores are being studied with great care in the laboratory, for they are an invaluable index of climate and precipitation over the past many hundreds of years. Their layers are studied in much the same fashion as tree rings are studied. From the first hole in Greenland, the 1912 layer was identified by the ash from a volcano which erupted in Alaska. The dust from the great explosion in 1883 of the volcano Krakatoa, in the East Indies, will be a help in checking the dating of the annual layers of precipitation in the cores. Because precipitation is lower in the Antarctic than in Greenland, it is expected that this ash layer will be found at a depth of about 150 feet in Greenland and at about 60 feet in the Antarctic.

The great ice sheet of the Antarctic, over 6 million square miles in extent, cannot be studied in anything but a spotty fashion. However, teams of glaciologists, seismologists, and support personnel are traveling by tractors and special over-snow vehicles thousands of miles across the ice in a series of traverses to obtain the profile of ice thickness across the continent and to attempt to learn something of the underlying terrain, or formation of the ice-covered earth. For example, after the Byrd Station was established some 600 miles from Little America by a tractor party, a traverse team then crossed the ice shelf from Little America and continued to Byrd Station, exploring the ice as it went.

The surface ice is examined by taking samples and determining the density, digging shallow pits to learn about the layers of the most recent several seasons, and making measurements of the temperature and heat conductivity of the ice. The deep ice is explored by setting off small explosions on the surface and by listening to echoes reflected by the bottom of the ice and by any deeper layers of the earth's crust. The time the echoes take to return allows calculation of the depth of the ice.

During this first traverse it was discovered that Byrd Station, at an elevation of about 5,000 feet above sea level, stands upon ice almost 10,000 feet thick. Further explorations will reveal whether this is a frozen fjord or inland sea and what part of this submergence may be due to the bending inward of the earth's crust as a result of the weight of the ice.

United States scientists at two locations in the Arctic basin are now making studies of the melting of the ice pack, the freezing of new ice, and the general relations between the state of the ice and the local climate. One of these stations, Drifting Station B, is on an ice island 7 miles by 3 miles in extent and about 140 feet thick. This block of ice was probably calved off the Ellesmere Island ice sheet many hundreds of years ago and has been circulating in the Arctic Ocean since, driven by the winds and ocean currents. This ice island, known as Fletcher's Ice Island, has been occupied previously by United States scientists in studies of the Arctic basin. It is currently at latitude 81°08′ N. and longitude 107°05′ W., about 611.8 miles from the North Pole.

The second station, called Drifting Station A, is now located at latitude 85°30′ N. and longitude 170° W., 310.5 miles from the pole. It is on the ice pack itself, on a floe a few square miles in area and only some 7 to 12 feet thick. Scientists there have noted that, during the past summer season, about 12 inches of ice on the upper surface has melted, while as much as 18 to 24 inches of new ice has frozen on the bottom of the floe. This observation will be placed in proper perspective when all the information on radiation from the sun, ocean currents, and temperatures of the air, ice, and oceans has been studied.

Oceanography.—The oceans, which cover about three-quarters of the earth, are a great storage trap for energy; the oceans are responsible for the fact that the climate of lands near seacoasts is more uniform than that of the interior of continents. Great ocean currents such as the Gulf Stream affect climates in the northern parts of the Atlantic Ocean. For example, Iceland and the British Isles have far less severe winters than they would have were the Gulf Stream not flowing. The surface currents of the oceans are related to the great wind systems, and it has been shown that the Gulf Stream, for example, follows the great clockwise atmospheric circulation in the Atlantic basin. Benjamin Franklin was one of the first to observe the nature of the Gulf Stream; Lt. M. F. Maury, the founder of the United States Navy Hydrographic Office, collected much information from mariners bearing on the set and speed of surface currents in this area, and several years ago an expedition of several ships, Operation Cabot, explored the Gulf Stream in a thorough fashion. It was found that, besides the main stream, there were many small eddies and side currents.

Recently, in a test of instrumentation developed by J. C. Swallow of the National Institute of Oceanography in England, the *Atlantis*, a research vessel of the Woods Hole Oceanographic Institution, and the British research vessel, *Discovery II*, explored the eastern edge of the Gulf Stream and were able to map for the first time the underlying flow of water. They found that, at depths of about 6,500 feet, there was either very little or very erratic movement; shallower depths showed set to the northeast, as expected, but at depths of about 9,000 feet, the current sets southwest at the relatively high speed of 8 miles per day. This new technique, in which the Swallow neutral buoyancy float is used, enables IGY oceanographers the world over to map both surface and relatively deep currents. Thirty-four countries are participating in oceanographic work for the IGY, some with ships and others with coastal and island observatories.

The deeper currents of the oceans have proved difficult to observe. Cold water is formed in the polar regions from melting ice; this water, being dense, sinks, displacing lighter water which then flows away from the polar regions toward the equatorial regions. Bottom topography such as ridges, canyons, and mountain ranges influences the flow of bottom waters, and it is possible that some bottom waters become trapped in basins It is not known whether bottom water makes a circuit from pole to equator and back in tens, hundreds, or thousands of years. The bottom waters play an important role in man's economy, for the extent to which the seas can support life is dependent upon the food supply in the water The bottom waters are rich in chemical nutrients, and, wherever these

waters upwell, there are found the great fishing banks, such as the Grand Banks off Newfoundland and the Peruvian fishing grounds.

Several United States ships have already made extensive cruises for the IGY. The work of the *Atlantis* has already been mentioned. The *Crawford*, also of the Woods Hole Oceanographic Institution, made a 4 months' cruise in the Atlantic. The *Crawford*, reoccupied many stations taken years ago by the German ship *Meteor* and discovered that there have been pronounced changes in the amount of oxygen dissolved in the Atlantic in the region of 15° south latitude. The difference in oxygen content over the past 30 years may mean that deep bottom water is not being formed as fast now as it was previously, but further data and analysis are needed for proper interpretation of the present observations.

The *Vema*, a research vessel operated by the Lamont Geological Observatory of Columbia University, has completed an extensive cruise in the South Atlantic Ocean, working along the coasts of South America and Africa, and crossing the Atlantic at high southern latitudes between Argentina and Capetown. The *Vema* cooperated with the *Bahia Blanca*, a survey vessel of Argentina, in making explorations of the submarine crust by seismic methods. Considerable marine biological work was also done, and Lamont has reported that living organisms—a small shellfish and a worm one-fourth of an inch long—were recovered alive from depths of 13,200 and 16,200 feet, respectively. Lamont scientists believe these to be record depths for retrievement of live marine samples. The *Vema* left New York in November for a 10-month trip to the Atlantic and Indian Oceans as the second phase of Lamont's oceanographic work for the IGY.

In the Pacific, the *Brown Bear* of the University of Washington worked in the Northeast Pacific Ocean last summer. The deep currents in that area were studied. The *Horizon* and *Baird*, research vessels operated by the Scripps Institution of Oceanography of the University of California, left San Diego in October for a 2-ship, 5-month expedition through the Central and Southeast Pacific. They will call at Tahiti (Samoa), Easter Island, Valparaiso (Chile), and Callao (Peru) and make seismic explorations of the submarine crust, study surface and deep currents, take bottom samples, and occupy about 40 oceanographic stations, where water samples down to great depths will be obtained for later analysis of chemical content. The *Jakkula*, of the Agricultural and Mechanical College of Texas, will cruise in the Caribbean Sea and western Atlantic in the summer of 1958.

Another part of the IGY oceanography program is the study of the mean sea level over the period of the IGY. It has been found from study of tide data that there seems to be an exchange of water between the Northern and Southern Hemispheres as the seasons change. Some of the change in mean sea level between summer and winter has to do with the expansion and contraction of water with temperature. New tide gages are being set up to supplement the existing network: Instruments are already operating in Bermuda, Iceland, and the Azores, in the Atlantic, and in the Caroline and Marshall Islands and, with the cooperation of French scientists, at French islands in the southeast Pacific. A station is in operation on Pitcairn Island under the supervision of a descendant of one of the mutineers of His Majesty's ship *Bounty*. At least 200 tide gage stations are being operated in the worldwide program, 32 of them by the United States.

In the Arctic Basin, United States oceanographers pursue their science from camps on the frozen ocean. The track of one of the stations has carried observers over what appears to be a newly discovered ridge, or underwater mountain chain. Scientists of the Soviet Union are doing similar work at two stations in the Arctic Basin.

In the Antarctic the ships of the various nations supporting scientific stations on the continent engage in oceanographic observations en route to and from the area. Thus, U. S. S. R. and New Zealand ships have added to our knowledge of these waters. Ships of United States Navy Task Force 43 are also exploring the coast, charting the bottom, and taking bottom and water samples for future study.

EARTH'S STRUCTURE AND INTERIOR

Seismology.—During the IGY, seismologists of 50 nations are obtaining earthquake information from almost all regions of the world, particularly in those regions not hitherto covered, as, for example, the Antarctic Continent. In addition, several new types of seismographs with wide range and high sensitivity have been located at observatories throughout the world. The Lamont Geological Observatory has constructed 10 special, long-period seismographs and has installed most of them at observatories ranging from Hawaii to Fiji and from Bermuda to the Antarctic. These long-period instruments are sensitive to surface waves with periods of about 400 seconds, generated only by the very largest

earthquakes. These wavelengths are so long that they penetrate to the interior of the earth, and, in fact, the whole earth itself may be set into vibration. Recently workers at Lamont have discovered the existence of certain intermediate waves with periods of about 100 seconds. These waves, which were previously only known in the crust in continental structures, have been identified now in the mantle, or the next layer beneath the crust. These waves permit better resolution of structural details than the longer 400-second waves, and study of their propagation is expected to provide new information on the distribution of materials in the interior of the earth.

Seismologists from the Department of Terrestrial Magnetism of the Carnegie Institution of Washington worked on exploration of the roots of the Andes Mountains in South America last summer and fall. They have found roots of unsuspected depths and are now working on their data to obtain better understanding of the crustal structure under this great mountain chain.

Seismologists of the United States Coast and Geodetic Survey have installed new seismic equipment in the Pacific at Truk and Koror and have been obtaining records of Pacific earthquakes. These new stations, together with those in the Antarctic, will add significantly to our knowledge of seismicity and the structure of the earth.

Gravity.—The earth is the attracting mass for all bodies on the earth. The earth, however, is not a perfect sphere, nor is its mass uniformly distributed. Furthermore, it is rotating. These conditions add up to the fact that gravity is not uniform and constant all over the earth. In general, because of the fact that the earth bulges somewhat at the equator and centrifugal force is greatest there, gravity is least at the equator and increases toward the poles. This effect is large enough to make a 200-pound man weigh 1 pound more at the pole than at the equator. In addition to this nonuniformity, great continental mountain masses, underground ore bodies, undersea mountains, and, in general, the uneven distribution of mass around the crust of the earth, contribute to local anomalies, some of which may be sufficiently large to deflect a plumb bob away from the vertical. Although this deflection is less than 10 seconds of arc, there are a few locations—Puerto Rico is one—where it exceeds 1 minute. This effect is significant in geodesy wherever geodetic control depends on astronomical observations.

The IGY program in gravity is aimed at increasing the reliability of measurements of gravity over the world, particularly in providing very accurate and reliable measurements at certain key locations to provide connection points between the gravity networks of various countries. Many measurements have been made already, including observations in the Arctic basin taken from United States IGY stations on the drifting ice. An important new station is located in Antarctica, where first-order measurements of gravity were made to provide a calibration for future measurements in the interior.

The first successful surface measurements of gravity on the open sea were made on November 22, 1957, by J. Lamar Worzel of the Lamont Geological Observatory, who used a sea gravimeter developed by Anton Graf of Munich. In the past, gravity measurements for oceanic areas required measurements aboard submarines at quiet depths below the surface. The difficulty of obtaining and fitting submarines for this purpose made it impossible adequately to survey the seas: only about 4,000 such measurements have been made throughout the world. The new instrument, mounted on a gyrostabilized platform, will make it possible to obtain data simply and quickly anywhere at sea with a precision of one part per million, similar to that attainable on land.

As the moon rotates around the earth and the earth rotates around the sun, the solid earth undergoes the same kind of tidal bulging that occurs in the oceans, although, of course, by a much lesser amount. Yet, it is enough to be observed with the most sensitive gravimeters. As the earth heaves in tidal motion, the distance of a point on the surface from the center of the earth changes by a small amount, perhaps a few tenths of an inch to several inches. This can be detected directly by instruments which are now in use recording the "pulse" of the earth, instruments which are sensitive to one part in one billion of the average value of gravity.

Latitudes and longitudes.—Scientists of 29 countries at 45 IGY stations around the world are in the process of determining longitudes and latitudes more precisely. Besides making transit observations at 3 stations, the United States is furnishing 21 of the moon position cameras developed at the Naval Observatory for use at stations in the United States and throughout the world; the first camera is now in operation at the United States Naval Observatory in Washington, D. C. When used in conjunction with the Danjon impersonal astrolabe, this instrument will permit more precise location of the earth's land masses than was hitherto possible.

IGY DATA

The preceding sections suggest the nature of the IGY activities as shown by the United States IGY effort in the first few months of the program. With 67 nations cooperating in the endeavor and some 10,000 scientists and technicians making observations and measurements at more than 2,000 stations, the volume of data stemming from the program will be considerable. To insure the safety of the raw data and their accessibility, the international IGY committee has approved the establishment of three world data centers.

World Data Center A is located in the United States and has 11 subcenters: visual auroral observations (Cornell University); instrumental auroral observations (University of Alaska); airglow and ionospheric physics (National Bureau of Standards, Central Radio Propagation Laboratory); cosmic rays (University of Minnesota); geomagnetism, gravity, and seismology (U. S. Coast and Geodetic Survey); glaciology (American Geographical Society); latitude and longitude (U. S. Naval Observatory); meteorology (U. S. Weather Bureau, National Weather Records Center); oceanography (Agriculture and Mechanical College of Texas); solar activity (University of Colorado, High Altitude Observatory); and rockets and satellites (National Academy of Sciences).

World Data Center B, operated by the U. S. S. R., has two subcenters. The first, at Novosibirsk, includes meteorology, geomagnetism, longitude and latitude, glaciology, oceanography, seismology, and gravity. The second, at Mocsow, includes aurora and airglow, ionospheric physics, solar activity, and cosmic rays.

World Data Center C, operated by several nations in Western Europe and the Pacific, has the following subcenters: geomagnetism (Denmark and Japan), aurora (Sweden and Great Britain), airglow (France and Japan), ionosphere (Great Britain and Japan), solar activity (Switzerland, Italy, Great Britain France, German Federal Republic, and Australia), cosmic ray (Sweden and Japan), glaciology (Great Britain), meteorology (World Meteorological Organization, Geneva), and seismology (International Central Seismological Bureau, Strassburg).

Each data center will acquire a complete set of all IGY data. Each center will archive and index its compilation of data, holding it accessible to research workers. Schedules for the orderly flow of data into the centers have been arranged. These schedules vary, depending upon the nature of the data in a given discipline and upon the definition of a reasonable "lot" of data to simplify the handling problems. A "lot" of data may be 1 month's observations in one field or several months' observations in another.

The procedures in handling data and forwarding them appropriately involve a series of steps of the following kind: (*i*) Collection of a "lot" of data at a field station, (*ii*) transmittal of the "lot" to the home laboratory of the field station, (*iii*) checking of field data at the home laboratory, (*iv*) transmittal to one of the world data centers, (*v*) copying of the data by one world data center for the other two and appropriate transmittal, and (*vi*) indexing and archiving at world data centers.

The data centers are in operation, and data are flowing into the centers. The steps outlined above lead to a peak early in 1958 and a steady 18-month plateau through at least the first 6 months of 1959, followed by a clean-up period extending probably into the first quarter or so of 1960 (1).

NOTE

1. The preparation of this narrative would not have been possible without the cooperation of many scientists and institutions engaged in the IGY program. Although some of them are mentioned in the text, it has not been possible in this summary to refer to all. The United States States IGY program has only been possible because so many individual scientists as well as public and private institutions have participated and cooperated in the endeavor. Particular acknowledgment is made to members of the National Academy of Sciences' IGY staff who have helped in the preparation of this report: Stanley Ruttenberg, Phillip Mange, John Hanessian, Jr., and John Truesdale.

Mr. FULTON. As a matter of fact, I was going to ask your agency to prepare a short summary of the results of the Vanguard and Explorer programs that are going to be explained on Thursday.

Dr. WATERMAN. Good.

Mr. FULTON. Next I would like to have the documents put in the record, or excerpts or summaries of them, showing that you have

been assigned through your agency to participate in the International Geophysical Year or, if there is correspondence, as to methods of setting them up. Your relationship should be explained, if you will, with the other agencies in the United States that are likewise participating so that we can have an overall view of what the United States has been doing in the IGY.

Dr. WATERMAN. Good.

Mr. FULTON. Again, if it is not too much, I would likewise appreciate your submitting a short history of the start of the IGY, how it happened to build up, and possibly an account of the conference in Barcelona, Spain.

Dr. WATERMAN. You mean the international planning or our own plans in it, or both?

Mr. FULTON. I would like to know generally, have it collected and collated in one spot, and show how these plans developed, for the benefit of the layman rather than have the information appear in all the scientific journals where the average person does not have a chance to get an overall view.

While we are talking about outer space, the question comes up, of course, as to its use. Now, we can either use outer space in the United States alone for our own purposes, or in conjunction with other people. Would you recommend that the United States have a United States policy for outer space to be implemented by a national space agency, both for civilian and military purposes?

That is, the policy rather than the implementation.

Dr. WATERMAN. The policy of the Agency is rather clear, if I understand you correctly. It is designed to study aeronautics and space exploration and the means to do this. So the policy is one of exploring space and to do the research necessary to make those explorations.

Mr. FULTON. So that the Columbus of 1958, 1959, or 1960, will be started on his exploration by the national space agency both as to planning, research and development and implementation with hardware?

Dr. WATERMAN. Right.

Now, the military have their own side of this which is important of course. So they similarly have a mission which, without going into any detail, would be to conduct the necessary research and development to provide for vehicles which can accomplish military missions in space.

Mr. FULTON. At what level do you think these satellites that circle the earth are dangerous to our United States security? Is it 50 miles, 60 miles, 100 miles, or 200 miles?

Dr. WATERMAN. That gets into a technical question as to the manner in which they could be a danger to our security.

I believe there has been fairly good evidence that a satellite as such is not a danger to the national security in the sense that most people think it is. It is not dangerous like an airplane because it cannot drop anything for the reason we just talked about, or if it could, it would be a very clumsy way. It would be a clumsy way to try to hit the target because the complications of getting it down to where you want it would be so very severe.

It should not be thought of then like an airplane traveling overhead or anything of that kind. It physically can do very little to endanger the national security.

Mr. FULTON. When you get out to the reaches of 150 miles at the perigee of an orbit, there is no particular military danger to the United States because the facilities are not present to use it to meet military capabilities, or rather there is not the proper weaponry.

Dr. WATERMAN. I cannot quote an authority on this because it is not my area.

It seems to me as a military weapon the satellite cannot be regarded in the same kind of class of weapons as we have.

Mr. FULTON. If we use ion propulsion which can provide continuous thrust that can accelerate a vehicle which is launched in outer space up to some portion of the speed of light, it is not too far beyond the realm of probability that we could aim a vehicle at approximately the nearest star and actually reach it.

Dr. WATERMAN. That is true.

Mr. FULTON. So when we are talking of the solar system, it should not be taken that these distances are completely beyond us because they are not within our realm of practical comprehension now. We should keep our minds open?

Dr. WATERMAN. Yes.

I was thinking when I said this, of course, about the travel of people, because then it gets pretty complicated when you have these long times. It is another thing if you talk about travel of scientific instrumentation which is the best way to start an exploration.

To make trips of exploration with scientific instruments which can be made uncanny in what they can perceive and tell us about, is certainly the logical thing to do and their time does not give the same complication.

Mr. FULTON. Because this is a new idea committee and yours is one of the new idea departments of government or agency, has any thought been given to the starting of space platforms not from the earth?

For example, all the smaller planets that have been discovered from time to time in addition to the larger ones are simply small masses floating in space. If we have that amount of material already up in outer space and have a space vehicle within the planetary system, all we need to do maybe is go out and assemble these things that are almost weightless in an orbit.

For example, if you could get 150,000 pounds of material about 25,000 miles out in space, it would weigh 1½ to 2 pounds. So the problem would be to go around and get these things, gather them together, bring them in and move them about the earth. You do not have to talk about tremendous rockets; is that right?

Dr. WATERMAN. It is conceivable. It will be a long time before we might be in a position to do it, but this is certainly conceivable enough.

Then we could begin to cultivate the idea of space platforms not just going around like a satellite around the earth, but one that goes around wherever it feels like, with rocket propulsion of some kind, some kind of propulsion whose power supply is always available.

If that were done, then, of course, one would not talk about a space platform just going around the earth, but wandering around as it felt like.

Mr. FULTON. So with the material out in these small planets we might sometimes be working them and transforming them in outer

space rather than all this talk of getting the tremendous weights out from the earth's atmosphere.

Dr. WATERMAN. That is something we can keep in mind as we progress to further knowledge.

Mr. FULTON. At Edwards Air Force Base during April there was a rocket that carried 26,000 pounds just a few weeks ago.

Now, that is the weight of a large loaded freight car. Hence, we in the United States are moving in a direction where accelerating or moving these heavier weights into outer space comes within practical view, do they not?

Dr. WATERMAN. They do, with respect to overall weight. If you have to start them moving they still have the same amount of mass. That is to say, they have a great amount of inertia.

Mr. FULTON. But for a rocket to take up 26,000 pounds through one vehicle, is quite a heavy load to be moving.

Dr. WATERMAN. Yes.

Mr. FULTON. It is the equivalent of taking a loaded freight car in the air from a dead start?

Dr. WATERMAN. That is right. I do think that the important thing as we said before, is to look at this from the standpoint of how far can we get in the exploration of space and the study of the space around the earth. We should first do this by instruments and then move systematically and intelligently into the next phase and not get to talking too much ahead of time but take the steps logically in order as we find them feasible.

This is the economical way to do it and the only wise thing to do, to take them normally and intelligently and learn about them before taking the next step.

Mr. FULTON. You would study the photon propulsion, ion propulsion, solar energy propulsion as practical basic studies?

Dr. WATERMAN. Yes, indeed.

Mr. FULTON. And do these along at the same time as we do the other programs?

Dr. WATERMAN. Yes.

Mr. FULTON. We talked of the question of the poles of magnetic fields. When there is a pole in the magnetic field it actually gives off an ion emission. A pole in a magnetic field will give off an ion emission at the point of it?

Dr. WATERMAN. No, sir. The magnetic field as such does not have particles in the ordinary sense. It just has a magnetic force. The pole is just a center where the force converges or diverges from, but there are no particles involved like electrons or things of that kind.

Mr. FULTON. But there is a force there that could make, by proper use, some return?

Dr. WATERMAN. It could have an effect on other particles if they had magnetic properties.

Mr. FULTON. Maybe that is a better way to say it. So by an electronic effect on particles, if properly used, we might be able, from magnetic poles, to develop a force possibly in the earth's magnetic field. We might be developing a force that we do not know about? Is that not possible?

Dr. WATERMAN. It does not seem possible to me as I understand your point. You see, the magnetic field of the earth is a very small thing. As magnetic fields go, it is a very weak field indeed.

It does not take any great strength to keep the compass from pointing north. The space outside is even less than that. So it is a rather weak force.

What is conceivably possible is to generate electricity by using the speed with which these bodies go through the earth's magnetic field. That is just the principle of the dynamo.

You could perhaps generate electricity in some such way. That is rather farfetched, I would think.

Mr. FULTON. There is something I would like to refer you to, Then I will be through. That is the effect on the electronic characteristics of the world, the earth, through the action of these cosmic rays. We have not yet found out enough about them to see what electronic effect they do have.

For example, the Germans, originally, and the Japanese have been investigating these electronic variations on the earth's surface, and, in particular, the electronic pole that is around Washington here.

Would it be effective for you to study the electronic systems of the earth through the investigations in outer space, which would help us develop electronic instruments?

Mr. NATCHER. Will the gentleman yield?

(Discussion off the record.)

Mr. BROOKS (presiding). Mr. Ford.

Mr. FORD. This is the question I would like to ask and I do not think it is entirely clear for the record.

What is the distinct difference between the National Science Foundation and the National Academy of Science?

Dr. WATERMAN. There are several. In the first place, the National Science Foundation is an independent Government agency which receives its funds from Congress.

The National Academy, on the other hand, receives no funds from Congress but is outside the Government in the sense that it has its own autonomous existence, it elects it members and so on.

It operates largely by means of the National Research Council associated with it to perform studies for the Government agencies, for the Government and for other groups anywhere in the country, such as studies on scientific questions.

Where one wants a study made, it may advise the Government. In that case it may receive its funds for the cost of the study from the Government agency. It does not get funds directly from Congress in that sense.

The National Academy of Sciences is certainly the highest authority of science in the country and the most distinguished body of science in the country.

Mr. FORD. Is it chartered by the Federal Government?

Dr. WATERMAN. It is chartered by the Federal Government with these terms I pointed out. Sometimes it is called a quasi-Government agency because it has a charter from the Federal Government.

The CHAIRMAN. If there are no further questions at this time, we will adjourn. The committee will stand adjourned until tomorrow morning at 9:30.

(Whereupon, at 4:20 p. m., the committee recessed, to reconvene at 9:30 a. m., Wednesday, April 30, 1958.)

ASTRONAUTICS AND SPACE EXPLORATION

WEDNESDAY, APRIL 30, 1958

HOUSE OF REPRESENTATIVES,
SELECT COMMITTEE ON ASTRONAUTICS
AND SPACE EXPLORATION,
Washington, D. C.

The committee met at 9:30 a. m. in the Caucus Room, Old House Office Building, Hon. John W. McCormack (chairman) presiding.

Present: Representatives McCormack (chairman), Brooks, Hays, O'Brien, Natcher, Sisk, McDonough, Fulton, Keating, and Ford.

Present also: George J. Feldman, director and chief counsel.

The CHAIRMAN. The committee will be in order.

Dr. Waterman, I understand they had not completed questioning you yesterday.

STATEMENT OF DR. ALAN T. WATERMAN, DIRECTOR, NATIONAL SCIENCE FOUNDATION, ACCOMPANIED BY JAMES M. MITCHELL, ASSOCIATE DIRECTOR, AND WILLIAM HOFF, GENERAL COUNSEL

Dr. WATERMAN. Yes, sir.

The CHAIRMAN. Mr. Fulton.

Mr. FULTON. You were speaking of the magnetic influences on the earth and we were talking about the magnetic poles.

I have a question about what research has been done on the Vanguard and Explorer vehicles on magnetic plots.

Dr. WATERMAN. As far as I am aware, the satellites that have been taken up to date have made no magnetic observations.

Mr. FULTON. But you do have plans?

Dr. WATERMAN. Yes.

Mr. FULTON. Are you at liberty to say what kind of plans you have on the investigation of magnetic flux with respect to the earth?

Dr. WATERMAN. The experiment which has been designed for the purpose is one which measures the strength of the earth's magnetic field at points where the satellite is traveling and also records, therefore, any changes in the strength of the earth's magnetic field there.

Mr. FULTON. That will have a direct effect, will it not, on radio waves, electronic instruments and things that we refer to as static?

Dr. WATERMAN. Yes. This is part of the whole phenomenon. Any time there are electrified particles coming from the sun, for example, they have an effect on the earth's magnetic field and they have an effect on the ionosphere. Those are associated in affecting radio communication.

Mr. FULTON. For any system that we might perfect of worldwide television using vehicles or satellites as stations, we would have to know more about the various electrified particles and magnetic flux, the poles and things of that sort?

Dr. WATERMAN. That is correct.

Mr. FULTON. Thank you. That is all, Mr. Chairman.

The CHAIRMAN. Mr. Feldman.

Mr. FELDMAN. Dr. Waterman, what is your definition of space science?

Dr. WATERMAN. There is no official definition made by science, as far as I know.

Mr. FELDMAN. What is your definition of space?

Dr. WATERMAN. Space is one concept which the sciences over the years have had trouble in defining rather precisely. This recalls an article in the early days after the publication of the Einstein theory and attempts to explain it when a physicist offered to explain it in words of one syllable, and he defined space as "Where we are and where we ain't."

Really I suppose a physicist would define it something like this. We can observe matter, substance, so that space is where we actually do or may expect to observe matter, or radiation from matter. But, of course, it is a very broad term. In this context obviously it means the region outside the earth's atmosphere.

Mr. FELDMAN. I would like to refer you to line 7 of page 2, section 2 of H. R. 11881, which is the administration's bill introduced by the chairman of this committee. It reads:

> Except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations, in which case the agency may act in cooperation with, or on behalf of, the Department of Defense.

On April 2, 1958, there was a memorandum for the Secretary of Defense and chairman of the National Advisory Committee for Aeronautics, signed by the President.

In paragraph 3 it says:

> The ultimate potential of space cannot now be fully grasped. Since some of these potentialities clearly have significance from the standpoint of our national security the Department of Defense will have the continuing interest in the programs to be undertaken and will continue to sponsor programs which may be peculiar to, or primarily associated with, military weapons systems and military operations as well as research and development which may be of a general supporting character.
>
> Furthermore, I desire that the skills and experiences that have been developed within the Department of Defense be fully utilized in supporting civil space programs. However, it is appropriate that a civilian agency of the Government should take the lead in these activities related to space which extend beyond the responsibilities customarily considered to be those of the military organization.

Now, we know that a lot of space research, a lot of development in connection with space satellites and so on, have both military and civilian significance.

Under the language which I just read, how would you determine what is customarily considered to be those of a military organization or primarily associated with weapons systems of military operations? How could that be determined?

Dr. WATERMAN. The clearest way, I believe, would be to have the Department of Defense state what in their opinion constitute mili-

tary research and travel in outer space and be able to justify before the administration that this was appropriate to their mission.

There are certain things which they already have, of necessity, found that they will have to do, such as the travel of ballistic missiles through outer space.

On the other hand, the new space agency, the NASA, would similarly outline their aims and these excursions for all sorts of purposes in outer space would be very much broader and the kind of observations they would make would form a much broader program than the Defense program itself.

So the clearest way is to ask each agency to state what its objectives are and what it seeks to do and be able to justify it before the Administration and then budgetwise before the Congress.

Mr. FELDMAN. Before you get a program underway it might take a long time, is that not so?

Dr. WATERMAN. I hardly think so, sir, because before an agency can have funds it must justify its program. I think this would occur naturally in the budget procedure. That would be my opinion, at least.

Mr. FELDMAN. There seems to be, at least in my mind, a striking difference between the directives and the wording of the proposed legislation. One seems to emphasize the fact that the military could take to itself anything of a military character. This might include about everything in the space vehicle category, because they are just as concerned with weather and communications and related things, even cosmic ray studies and matters of that sort, as the nonmilitary is.

Dr. WATERMAN. There are degrees of interest there, I believe. It is true, of course, that the military are concerned with weather, but so is the civilian population. As to the interest in terms of volume and quantity, certainly the civilian interest is overriding there. It seems to me that one could keep the same kind of distinction there is now between the Weather Bureau operations and other research in meteorology and what the services have an interest in, so that the observations made by the vehicles of this agency that are concerned with weather would be available to the Department of Defense. Then they could take that and build into it any special research which they felt was of particular military importance. This would also be a cooperative thing, but the civilian interest would be broader; that is my point.

Mr. FELDMAN. You do not feel there will be any difficulty?

Dr. WATERMAN. I should think not. On most subjects this could be handled the way it has been before, like meteorology, for example. There would be new subjects where it might be necessary to have some decision made as to relative responsibilities, but most would have to be cooperative in many ways.

Mr. FELDMAN. I refer you now to section 6 (a) (1) of the proposed legislation beginning with line 18 on page 5. It reads:

> The Agency shall develop a comprehensive program of research in the aeronautical space science.

As distinguished from the next section, which reads:

> The Agency shall plan, direct, and conduct scientific studies and investigations of the problems of manned and unmanned flight within or outside the earth's atmosphere with a view to their practical solution.

Does not your organization have a great deal to do with the space sciences?

Dr. WATERMAN. Our function, of course, is to deal with basic research wherever it may be found, including outer space and astronomy and the problems of basic research with respect to the earth, geophysics, and all the rest of it.

So we are on the very basic side of this program and, therefore, have an interest in such matters as the question of what is meant by "space science" in section 6 (a) (1) which reads "develop a comprehensive program of research in the aeronautical and space sciences."

I consider, Mr. Chairman and gentlemen, as the major aim of this Agency the science of space exploration. The reason for establishing it is because it is a hard, difficult, complicated task to proceed with the whole art and science of providing means of getting objects into space beyond the earth's atmosphere, whether they are going to go into orbit, or whether they are going to travel out further.

This is a very difficult undertaking and it is essentially practical in nature. So that the core of the research they do should be directed toward solving the problems which they are going to encounter. These are quite severe and need very concentrated attention.

So, one might say, as specifically and practically stated in section 6 (2):

> Plan, direct, and conduct scientific studies, investigations of problems of manned and unmanned flight within or outside the earth's atmosphere with a view to their practical solution.

This is the main core of the Agency's mission.

Section 6 (a) (1) is intended to give the Agency some latitude to do research which provides a better understanding of these problems, but which is not specifically and directly designed to make a better rocket or better guidance or something like that.

I should say I do not know exactly what one means by space sciences. One could state, "Develop a comprehensive program of research in the aeronautical sciences and space flight," which I think might provide that degree of generality which might be needed without defining what is meant by space science.

Space science would be subject to a large number of interpretations.

Mr. FELDMAN. It might conflict with what you are doing; is that not so?

Dr. WATERMAN. I do not really think we have a conflict, because we are both interested in the same thing, though we have different responsibilities.

In the Science Foundation we would be very much interested in providing observations in pure research rather than the ones which bear on the problems of flight. They would be interested in this as well because of the effect it would have on their programs.

I believe that they would turn to us because we have a staff and experience in the pure sciences, for cooperation here, as outlined on the next page, I think it is.

Mr. FELDMAN. Let us get down to on the next page, line 3:

> Arrange for participation by the scientific community in planning scientific measurements and observations to be made through use of aeronautical and space vehicles, and conduct or arrange for the conduct of such measurements and observations and provide as appropriate for dissemination of data collected.

Do you not think that that should be clarified by some amendment which will tie it in with your organization?

Do you have any thought about some language that could be used there?

Dr. WATERMAN. As I state in my testimony, we would expect to cooperate in accordance with our interests. It could be stated that if the Government's interest in planning scientific measurements of the pure research variety should be given special recognition, the section could state "in cooperation (or in collaboration or in consultation) with the National Science Foundation arrange for participation by the scientific community," or words to that effect.

The CHAIRMAN. Would not that take away what you testified to yesterday, that the space agency would be more or less an organization for outer space?

Dr. WATERMAN. It would, in solving problems on how to deal with travel in outer space and to explore possibilities of that travel.

The CHAIRMAN. Of course, we have these complications. I do not blame you and the others for protecting the Foundation. I am a great supporter of foundations.

But we are going to have a new agency. We want to know what the jurisdiction is. The executive should be very frank with the committee in stating the objectives so that we know what the objectives are.

Before we establish an agency, we certainly want to eliminate as much duplication as possible. There is bound to be a twilight zone, I recognize that.

Dr. WATERMAN. I do not know of any that would quarrel with the provisions of 6 (4) on page 6. So the question I was asked by counsel is whether there should be an explicit statement of the function of the Foundation here.

If the committee feels this is desirable it could be stated "in consultation (or in cooperation) with the National Science Foundation." The National Academy of Sciences, of course, is another organization which might well be consulted here.

As I stated yesterday, I believe we would have full cooperation here because an agency is not likely to turn into areas that require a completely new staff for the purpose if it can find that another agency can furnish that kind of advice.

Mr. FELDMAN. I have no further questions.

The CHAIRMAN. Thank you very much, Dr. Waterman. For myself, as chairman, and other members of the committee, I thank you and the other gentlemen.

Dr. WATERMAN. Thank you, Mr. Chairman.

The CHAIRMAN. We would like to have you look over the bill and if you have any suggestions, particularly how it could be strengthened, we shall be very glad to hear from you.

Also the declaration of purpose, that has some importance.

Mr. FULTON. Would you put in the record, please, a statement of your relationships with other countries as well as anything that might have been done with the visit of the Russians to this country during the international geophysical year and what access they might have had to our information of a scientific nature?

Dr. WATERMAN. Yes, sir.

(The question asked above is answered below:)

MATERIAL FOR THE RECORD IN RESPONSE TO QUESTIONS OF CONGRESSMAN FULTON (VARIOUS PAGES), HOUSE SELECT COMMITTEE ON ASTRONAUTICS AND SPACE EXPLORATION

I. HISTORICAL BACKGROUND AND INTERNATIONAL ORGANIZATION OF THE IGY

The period July 1, 1957, through December 31, 1958, has been designated as the International Geophysical Year. It is a period of worldwide observations and studies of the sun, and of the earth and its physical environment, including its atmosphere and the space through which it travels. Sixty-six nations are taking an active part in the program.

The IGY is actually the third such scientific undertaking. During 1882–83, the first polar year, 10 nations, including the United States, conducted simultaneous cooperative scientific observations in the Arctic. Fifty years later the second polar year, 1932–33, was undertaken, in which 30 nations cooperated in observations primarily in the Arctic. Both of these periods contributed greatly to the store of basic knowledge in the geophysical sciences.

In April 1950 at an informal meeting of geophysicists in this country the suggestion was offered that, because of the tremendous advances in instrumentation that had taken place in the 1940's, consideration be given to holding a third polar year 25 years after the second, which would place it in 1957–58, a period of maximum sunspot activity. The suggestion was received with enthusiasm, and in subsequent discussions scientists throughout the world recognized the benefits of extending the planned program to encompass the entire earth and renamed it the International Geophysical Year to reflect the increased scope in coverage.

During the next 18 months the initial proposal was considered and supported by a number of international scientific groups, most of them members of the International Council of Scientific Unions (ICSU). The Mixed Commission on the Ionosphere endorsed it as did, also, in rapid succession, the International Scientific Radio Union, the International Astronomical Union, the International Union of Geodesy and Geophysics, and finally the International Council of Scientific Unions itself.

In 1951 the Executive Board of ICSU appointed the Comité Spécial de l'Année Géophysique Internationale (CSAGI), composed of representatives of the various scientific unions involved and of the World Meteorological Organization and the International Consultative Committee for Radio Communications. A Bureau of CSAGI was appointed consisting of Prof. Sydney Chapman (Great Britain), president; Dr. Lloyd V. Berkner (United States), vice president; and Prof. M. Nicholet (Belgium), general secretary. Later (in June 1957) Prof. V. V. Beloussov (U. S. S. R.) and Prof. J. Coulomb (France) were added as members of the Bureau.

In late 1951 and early 1952 CSAGI invited member nations of ICSU to establish special national committees to take part in the planning and guidance of the IGY. As the concept of the IGY expanded, invitations to all countries of the world were issued to join in the enterprise.

A coordinated worldwide scientific program for the IGY was synthesized from various proposals submitted by individual nations and modified through periodic meetings of CSAGI (Brussels, 1953; Rome, 1954; Brussels, 1955; and Barcelona, 1956). A fifth meeting of CSAGI is scheduled to be held in Moscow in August of this year.

II. UNITED STATES PARTICIPATION IN THE INTERNATIONAL GEOPHYSICAL YEAR

United States National Committee for the IGY

The National Academy of Sciences-National Research Council, a nongovernmental organization, as the adhering body on behalf of American scientists to the International Council of Scientific Unions and most of its Unions, was the group in the United States that received the CSAGI invitation for this country to participate in the IGY. In response to this invitation, the Academy-Council established in February 1953 the United States National Committee for the International Geophysical Year 1957–58, under the chairmanship of Dr. Joseph Kaplan, professor of physics at the University of California at Los Angeles. Dr. Alan H. Shapley of the National Bureau of Standards was named vice chairman, and Mr. Hugh Odishaw, formerly of the National Bureau of Standards, the

executive director. The committee membership included appropriate representation from the various scientific disciplines involved; subcommittees were named to cover the regional programs planned (Arctic, Antarctic, equatorial regions); and 13 technical panels were established to direct the program in the scientific disciplines of meteorology, geomagnetism, aurora and airglow, ionosphere, solar activity, cosmic rays, longitude and latitude, glaciology, oceanography, seismology, gravity, and in the programs of rocketry and communications.

Role of the National Science Foundation in the IGY

The Academy-Council recognized the importance of Government cooperation and support to the success of the United States portion of the IGY program. On November 25, 1953, the Academy-Council transmitted to the National Science Foundation the recommendation of the United States National Committee for the IGY that the Foundation be asked to take responsibiliy for obtaining and administering Government funds required to carry out the program and to coordinate the interests of Government agencies involved (attachment A).

After consideration of the recommendation and a study of the proposed program and budget, the National Science Board at its meeting of January 29, 1954, endorsed the program and the Foundation's participation in it. With the endorsement of the administration, the Foundation proceeded with the implementation of United States plans, including the coordination of Government interests in the program.

After submission of the proposed budget and program for the IGY to the Bureau of the Budget, and the submission of letters of support for the program to the Bureau of the Budget from the Departments of State, Defense, and Commerce, the Atomic Energy Commission, and the Office of Defense Mobilization, the President approved the program and included the requested amount for the National Science Foundation in support of the International Geophysical Year in a supplemental appropriation request for fiscal year 1955. Action by the Congress was approval of an initial appropriation of $2 million for the IGY program (Supplemental Appropriations Act of 1955, 83d Cong., 2d sess.). Subsequent appropriations to the National Science Foundation for the program have been $10 million (Independent Offices Appropriations Act of 1956, 84th Cong., 1st sess.); $27 million (Second Supplemental Appropriations Act of 1956, 84th Cong., 2d sess.); $2 million (Second Supplemental Appropriations Act of 1958, 85th Cong., 2d sess.). The total amount therefore appropriated to date for the IGY program is $41 million.

Fundings of the various projects in the United States IGY program have been administered through the regular grants procedure of the National Science Foundation, upon recommendations received from the United States National Committee for the IGY. Grants or transfers to 45 institutions or agencies have been made to March 31, 1958, totaling $34,871,678 (attachment B).

Two special reports on the IGY program have been made upon request to congressional committees. On March 28, 1956, there was transmitted to the chairman of the Subcommittee on Independent Office Appropriations and Government Matters, United States Senate, a special report on the International Geophysical Year prepared for the Senate Committee on Appropriations, which was published in May 1956 as Senate Document 124, 84th Congress, 2d session (attachment C). On May 1, 1957, members of the United States National Committee for the IGY, representatives of the Committee's Secretariat and the National Science Foundation appeared before the Subcommittee on Independent Offices, Committee on Appropriations, House of Representatives, at the request of the chairman, to give a progress report on the IGY program. This report was published as "Report on International Geophysical Year," Hearings Before the Subcommittee of the Committee on Appropriations, House of Representatives, 85th Congress, 1st session (attachment D).

Other Government agencies involved in the IGY

The National Science Foundation, in order to assure coordination, has worked closely with other Federal agencies having an active interest and role in the IGY. These include the Department of Defense, Weather Bureau, National Bureau of Standards, Coast and Geodetic Survey, and Geological Survey.

The Department of Defense is involved in the IGY program primarily in the Antarctic and earth satellite projects. In the case of the former, the Defense contribution includes all logistics support, construction of facilities, stationkeeping personnel, and transportation services. For the satellite program, agreements were reached with the Department of Defense to develop and supply suitable launching vehicles, procure range operation costs, place satellites in orbit,

and establish confirmation of the orbit, the latter involving certain parts of the ground electronics setup. The National Science Foundation agreed, as far as the earth satellite project was concerned, to furnish funds for the scientific instrumentation, parts of the electronics ground operations, the optical-tracking ground station network, and the substantial part of the radio-tracking and telemetry network.

III. RELATIONS WITH OTHER COUNTRIES PARTICIPATING IN THE IGY

As far as relationships with other countries are concerned, the IGY is a nongovernmental type of undertaking. Agreements and understandings are between the scientists and the scientific organizations of the countries and are not characterized by formal agreements, treaties, or other types of documentation that are used in the case of intergovernmental relationships.

To "qualify" as a participant in the IGY it is necessary only that the scientific organization representing a country agree to carry out certain appropriate scientific and geophysical programs within its own continental limits, possessions, or territories in which it has traditionally had an interest, that it appoint a special committee of appropriate scientists to organize and execute its scientific program, and that it agree to make the data therefrom available through planned IGY world data centers.

In order to assure ready availability of all data, the CSAGI has recommended the establishment of three "world data centers." One of these centers will be in the United States, one in the U. S. S. R., and the third divided between Western Europe and Japan.

The following principles will govern the operation of these centers:

1. Each world center will receive original copies of IGY data from countries that elect to use that particular center as the archives for their data. In general, it is anticipated that countries in the area of a given center will send their data to that center, although there may be exceptions. The important point is that all original IGY data will go to one or the other of the three centers now planned.

2. Each center will immediately make copies for the other world centers of the original data it receives and will supply these copies free of charge.

3. Any institution or individual may request from a world center copies of data, which will be supplied at the cost of reproduction. Every effort will be made to keep such costs low.

Thus three complete sets of IGY data are planned, conveniently located to supply requests from scientists throughout the world.

The United States World Data Center has been organized as a series of some 12 primary archives in the various disciplines, located at appropriate institutions and agencies, with a central coordination office presently at the National Academy of Sciences for handling requests.

Through the National Academy of Sciences representation at various international planning meetings held in connection with the IGY, American scientists have dealt with their colleagues from other nations in the planning of the overall scientific program. To date, 66 countries are actively involved in the IGY (attachment E).

Not all of these countries have been represented at the various international planning meetings referred to, but certainly all of the major countries have been so represented.

There has been held in the United States to date only one minor conference as far as IGY matters are concerned, and that was the Conference on Rockets and Satellites convened in Washington, D. C., the latter part of September and early October 1957. Representatives from 13 countries attended, including a delegation of three scientists from the U. S. S. R. A fourth Soviet scientist was present in his capacity as the vice president of the Special Committee for the International Geophysical Year under the International Council of Scientific Unions. This is the only occasion that Soviet scientists have visited the United States in connection with IGY activities. There was no formal exchange of IGY data at this time, although there were informal discussions on many unclassified aspects of satellite and rocket instrumentation and scientific research connected therewith.

IV. RESULTS OF THE IGY AND REMAINING CALENDAR OF EVENTS

Results of the IGY

Since the start of the IGY last July, stations throughout the world have been in operation. While a comprehensive evaluation of results achieved cannot as yet be made, certain real gains have been reported. In January of this year the

United States National Committee for the IGY prepared a status report on the first 5 months of the IGY, based primarily on United States activities. From this report it is clear that the IGY will produce basic scientific information that can be of great benefit to mankind.

Some of the things that have been learned, for example, include the recognition of a transient layer below the normal known layers of the ionosphere caused by intense solar activity. This effect is responsible for the blacking out of long-range radio communication circuits during periods of intense solar disturbance.

A second result is the confirmation of the simultaneous occurrence of auroral displays in both the northern and southern hemispheres. This serves to confirm the theory that aurora are produced by charged particles coming in from the sun that are deflected toward the two magnetic poles of the earth. The third interesting and highly significant observation is the possibility that the region high above the atmosphere, which had originally been thought to be relatively devoid of matter, now appears to contain electrified particles (ions), which may either be due to a miscalculation of the upper limits of the earth's atmosphere extrapolated from relatively low altitude observations or an extension of the solar corona to include the earth or a combination of both.

In the field of satellites, five scientific satellites have been launched as part of the IGY program. Two of these have been launched by the U. S. S. R.: 1957—Alpha (Sputnik I) on October 4, 1957; 1958—Beta (Sputnik II) on November 3, 1957. To date the Soviets have not released information on internal observations, although they have indicated that temperature measurements of the casing and certain interior parts were made. Presumably they are still working on the reduction of the telemetered observations.

The United States has placed three satellites in orbit: 1958—Alpha (Explorer I), launched by the Army on January 31, 1958; 1958—Beta (Vanguard 6-inch sphere), launched by the Navy on March 17, 1958; and 1958—Gamma (Explorer III), launched by the Army on March 26, 1958.

Reports on the experimental results of United States satellites were presented by the United States National Committee for the IGY at a special meeting at the National Academy of Sciences on May 1, 1958. These results, of a very preliminary nature, reported such things as the temperature ranges encountered by the satellite shell and its internal instrument package, the numbers of micrometeoric impacts, and, most important of all, certain cosmic ray counterresults that imply regions of high radiation intensity at distances of several hundred miles above the earth's surface. The exact nature of this radiation is not at the present time completely understood, but additional experiments will undoubtedly be planned to resolve the problem.

FUTURE CALENDAR OF EVENTS

Present–December 31, 1958: Continuation of active operational period at all IGY stations.

August 1–9, 1958: Fifth reunion of CSAGI, Moscow, U. S. S. R. (Major areas for discussions: publication of IGY data and other material, data flow and data centers, aspects of rocket and satellite programs, work in the Antarctic following IGY. Working groups in all disciplines will meet.)

Dates uncertain: Several planned launching attempts of additional IGY scientific earth satellites.

Summer or fall 1959 (post-IGY period): Possible international meeting of participating IGY national committees to be convened in the United States by the United States National Committee for the IGY. (Discussion of further results and closing out of affairs of CSAGI).

April 15, 1958 (66 countries).

The CHAIRMAN. Thank you very much, Doctor.

The next witness is Dr. Lloyd V. Berkner, president and chairman of the executive committee, Associated Universities, Inc., of New York City.

Admiral, we are very glad to have you appear before us and testify. We welcome you.

We also understand that Mr. Frederick C. Durant III, of Massachusetts, former president of the American Rocket Society, is also here. Is that right, Mr. Durant?

Gentlemen, your testimony sort of interrelates with one another. The other day we found it very handy for their convenience, as well as that of the Committee, that those who are similarly situated each give their primary testimony and then the members of the Committee could address questions to both at the same time, because that makes it informal. I think that produces better results.

Dr. BERKNER. I will be happy to join Mr. Durant.

The CHAIRMAN. I personally do not like the stiffness of hearings. I like the informal atmosphere.

Do you have a prepared statement, Admiral?

Dr. BERKNER. Yes, sir.

The CHAIRMAN. You may proceed.

STATEMENT OF DR. LLOYD V. BERKNER,[28] PRESIDENT AND CHAIRMAN, EXECUTIVE COMMITTEE, ASSOCIATED UNIVERSITIES, INC., NEW YORK, N. Y.

Dr. BERKNER. Mr. Chairman, I am glad to be here with you this morning.

Mr. Chairman and members of the select committee, I am pleased to respond to the invitation of your chairman to discuss future policy and legislation on the subject of space exploration and research.

Since the first discussions of geophysical research with instrumented earth satellites in Europe in 1954, I have had the task of coordinating the plans for international research activity using instrumented earth satellites acting as the reporter for Rockets and Satellites of the Special Committee for the International Geophysical Year.

In less than 4 years we have progressed from the initial plans to the stage where three United States satellites are now circling overhead to collect scientific information of our environment that was beyond our fondest hope of access only a few years ago.

May I first take this opportunity to express my admiration to the Congress in their response to the request of the President and of the scientists through the National Science Foundation, for their perspicacity in providing financial means whereby our initial program of research with satellites is now being carried out.

In 1955, it was by no means clear to the uninitiated that a program of satellite launching would be justified or would produce such major scientific results.

I recall with pleasure, many hours of painstaking examination of these ideas by the House Appropriations Subcommittee under Chairman Thomas and by the Senate Appropriations Subcommittee under Chairman Magnuson. It is a tribute to the wisdom of our legislators that they were able to see the vital need for action, and to take the needed initiative in appropriating the funds that made possible the satellites. that are now carrying on their observations overhead.

---

The very fact of these hearings illustrates the strength of our democratic processes in undertaking unusual measures that require great vision for the welfare and benefit of our citizens and of men everywhere.

The need for action at this time is clearly stated in the declaration of policy of the bill under consideration. I wish to testify in support of the general measures provided by that bill.

This need is more fully discussed in the President's message to Congress of April 2, 1958, and in the Introduction to Outer Space prepared by the President's Science Advisory Committee. To the former I fully subscribe, and to the latter I, of course, contributed as a member of that Committee.

In considering the future of space research, may I emphasize the great importance to every citizen of the knowledge that will be gained from such research.

Recently, under the title of "Man's Space Satellites," appearing in the bulletin of the Atomic Scientist—pages 106 to 111—of March 1958, I have described some of these research problems in considerable detail.

Many of these are discussed in much more detail in the Manual on Rockets and Satellites, Annals of the International Geophysical Year, that will be published by Pergamon Press next month in an illustrated volume of nearly 500 pages. This will be a very useful source of material.

Man's ability to improve his knowledge of meteorology is of immense immediate importance. The observations and measurements that can be made from space, looking down on the earth, are of a kind that give a new dimension to meteorological research.

We have, within our grasp, the means to see storms form and move and dissipate on a global scale—in fact, the means to count the number of storms from time to time and to see their interaction on one another.

We can see weather fronts grow in intensity, either visually or electromagnetically, see the genesis and movement of hurricanes, and obtain descriptions that, when coordinated with surface and radiosonde observations, can immensely improve the extent of our knowledge of weather.

The satellite can map the incoming and outgoing energy everywhere over the earth so that we can localize the energy sources that operate the atmospheric engine that gives us our weather.

The power of the satellite as a scientific instrument gives real hope that, coupled with other necessary observations and measures, man can learn the physical reasons why destructive droughts occur, or catastrophic windstorms and flood-producing rains are generated from a usually well-behaved atmosphere. Certainly, in the field of meteorology, even small advances in knowledge have values measured in billions of dollars annually.

Looking upward from the earth, man can now see the universe in its full chromaticity from the shortest to the longest wavelengths—from the slowest to the fastest particles coursing through space. In the satellite, he is no longer insulated by his blanketing atmosphere from the most interesting events of the universe.

He can now study all the clues to the physical behavior of the sun and the planets and the stars.

There is no doubt that these new studies in the next few years will lead to a much better understanding of nature—an understanding that will have many and diverse applications in our day-to-day life. Just as the study of astronomy and matter has given us our present day engineering with its power to turn nature to our benefit, so the new studies from space will vastly multiply this power.

Thus, even though the ticket to space is expensive, the payoff will be correspondingly high, and this can be prophesied with some certainty.

I mention the wide range of research that will be done from space vehicles, since it bears directly on the functions of the agency specified in section 6 of the bill, and particularly in section 6a4.

Almost every kind of scientific activity will be involved in space science in one way or another. In some cases, like astronomy or some aspects of geophysics and of physics, nearly the whole scientific activity will be carried out from a position of vantage in space.

Therefore, it would be completely unrealistic and undesirable for the Aeronautics and Space Agency to be responsible for all of the scientific activity to be done in space.

The bill under consideration wisely recognizes this problem, and provides that the Agency shall "arrange for participation by the scientific community in planning scientific measurements and observations to be made through use of aeronautic and space vehicles, and conduct, or arrange for the conduct of such measurements and observations."

I interpret this language as meaning that any qualified scientist can plan and prepare a useful space experiment at his university or in his laboratory with the expectation of getting it into space with the cooperation of the Space Agency within the restrictions of the funds and technology available.

This means that the best of American science, wherever it is found, can have access to space through the means and cooperation that its Government provides. This provision ensures the healthy growth of space science and avoids a governmental monopoly on one of the important scientific activities of the future.

I deem it a most important and essential provision of the present bill.

Likewise, section 6 (b) (1) to (13) each become essential to the effectuation of this broad policy.

Please do not misunderstand that I would raise objection to the provision— of subparagraph 6 (a) (2) above—that the Agency have full authority to initiate its own space research directly.

Certainly the Aeronautics and Space Agency could not be effective without that authority.

But in practice, I would visualize that the Agency would serve the interests of American science best by encouraging and abetting and aiding scientists outside the Agency who are best qualified to design and carry out particular space experiments using the vehicles of the Agency.

But to do this, the Agency must develop its own scientific expertise and it will find many new space problems where only its own staff can devise and conduct the experiments.

The optimum balance of the Agency's aid to American science in the conduct of space experiments, and in the design of its own primary

scientific activities, will require great skills in administration. Therefore, this must be kept in mind in specifying the form of organization of the Agency.

One might argue that space technology should be developed under the wing of the military services. Undoubtedly, the space vehicles have military implications of their own, quite apart from the military capabilities implied in the ability to launch them.

Moreover, the great rockets required to launch heavy vehicles are available from the military stockpile, and at the moment the greatest skills in rocketry are under the supervision of our Department of Defense.

Consequently, it might be thought that greater economies of effort could be achieved in this way. Certainly strong arguments can be advanced for military control of future space development.

But these arguments have a certain superficiality that misses the significance of the space as a future social development. The extension of geography into space should be a peaceful project, as President Eisenhower has advocated.

Just as the initial planning for satellites for man's benefit was conducted in the friendly atmosphere of international scientific circles, so the future international discussions of space programs should be free of the rigid domination of the uniforms of the world.

This is not to say that the military organizations should not play their part in the conquest of space. Certainly they have many skills and facilities that are needed, and they have a legitimate interest in the subject.

But space conquest should be primarily for intellectual and social rather than military ends. We must recognize our conquest of space is a superb manifestation of man's control of his environment that far transcends its incidental military relevance to the interrelationships of men and nations. We must apply the results to our whole social and economic growth.

Our Nation faced a similar decision in planning the future of nuclear energy. Nuclear development has a relation to military strength at least equal to that of space technology. Yet our decision, and I believe it was right, was to place its direction under a civilian agency, the Atomic Energy Commission.

For nuclear energy had civil and peaceful as well as military implications. Whatever the defects of that organization, no one would suggest that it has in any way hampered the growth of United States military strength.

On the contrary, our nuclear military strength is in the unquestioned vanguard of our national scientific achievement.

At the same time, a civilian AEC provides the mechanism through which "atoms for peace" and other friendly international activities sparked by the atom, can aid in breaking down international tensions.

Similarly, the full scientific and social potentialities of space technology, in my opinion, can best be realized under a civilian Federal agency. The direct consequences of carefully designed space researches will react on every aspect of man's existence and will radically influence his adjustment to his environment.

The purely scientific problems involved are complex and their solution can be best achieved under civil auspices closely related to the academic atmosphere, because they transcend the normal limits of military technology.

Even the advanced rocket techniques that are needed must presently far outstrip the military needs, and, in fact, will often differ radically from military designs.

Certainly great laboratories will be required, and these should enjoy the intimate relationship to university activities that grows out of broad civil direction of national programs.

In the present state of unstable military equilibrium, it is natural that we should be concerned for our military strength and effectiveness. With the gravest consequences at stake, no nation can afford to tip the balance adversely by weakening its military strength.

But in facing the future of space technology with a biased emphasis on its military aspects, there is danger that we may fail to grasp the real opportunity for world leadership that space technology offers.

Militarization of broad problems such as space technology that affect all elements of our national community suggest a considerable danger of our Nation succumbing too completely to a psychology of military direction and control. Instead, a more balanced approach is needed through which all elements of our society, including the military, have an equal opportunity to contribute.

We must not forget that it was the Soviet Academy of Sciences and not the Red army, that negotiated the plans for the launching of the first earth satellites.

I would submit, therefore, that he specifications for Aeronautics and Space Agency contained in the declaration of policy of the bill in its present form, are not only wise, but in themselves suggest a civilian agency for their effectuation.

Moreover, the consolidation of the space activities, with the aeronautical activities now under the National Advisory Committee for Aeronautics, appears to be the best possible course. In the NACA, there is already our best national skill in aeronautical research. The future of space development is inevitably related to these skills very closely.

The addition of the responsibility for American space activities to the present responsibilities of the NACA represents a means for orderly growth of these skills that will strengthen both the aeronautical and the space capabilities of American science and engineering.

The enlarged Agency, to be most effective, must grow with a strong academic flavor to develop its strength in close collaboration with the science of American universities and institutions.

Therefore, its development should be more toward the academic, as contrasted to the commission form or organization. Here we must recall that the NACA, with its Board and its Director, has developed an effectiveness that is the mainstem of American aeronautical development and is the envy of the rest of the world.

I would, therefore, urge strongly and unambiguously that the organization of the Agency as visualized in the present bill be retained.

The NACA form of basic policy determination and direction has, in my opinion, already won the confidence of American science and industry. It has demonstrated its capability to cooperate with the Armed Forces to a maximum of effectiveness, thereby relieving them of much responsibility auxiliary to their task. It is a proven organization and it should be retained.

The challenge of space will not be simple to meet. From this challenge will evolve instruments and techniques and opportunities that

will enable man to view his problems with a new perspective, that will provide him with incalculable advantage.

Space technology represents a broad intellectual challenge that must be met by an equally broad response from all elements of our national community.

In my opinion, the present legislation recognizes that challenge and provides the means for the national character of the response. It subordinates expediency to the course of wisdom.

Thank you, Mr. Chairman.

The CHAIRMAN. In accordance with our understanding, we will hear from Mr. Durant.

The next witness is Mr. Frederick C. Durant III, of Everett, Mass., former president of the American Rocket Society and International Astronautical Federation.

You are connected with Arthur D. Little, Inc.?

STATEMENT OF FREDERICK C. DURANT III, FORMER PRESIDENT, AMERICAN ROCKET SOCIETY, AND INTERNATIONAL ASTRONAUTICAL FEDERATION

Mr. DURANT. I was for several years but last summer I joined the AVCO Research Laboratory.

The CHAIRMAN. We are glad to have you with us, Mr. Durant.

Have you a prepared statement?

Mr. DURANT. Yes, sir; I do.

The CHAIRMAN. I notice you have written two articles, one entitled "Commission on Astronautics, Academy of Sciences, U. S. S. R.", and the other one the International Astronautical Federation, IAF.

Mr. DURANT. Those I furnished to Dr. Sheldon of your staff simply as background material for your committee.

The CHAIRMAN. I think without objection we will insert both these articles in the record after you have completed your main statement.

You may proceed, Mr. Durant.

Mr. DURANT. Thank you.

Mr. Chairman and gentlemen, in contrast to all of the distinguished scientists who have appeared before you during the past few weeks, I have no such pretension. I am an engineer with chemical and aeronautical background.

However, I have devoted much of my professional life to rockets and guided missiles and, avocationally, to professional societies concerned with various aspects of space flight.

The record shows that my role has been one of an organizer and administrator. In a sense, I have promoted space flight for the past 10 years because of a deep conviction that man, by moving into this new dimension with instrumented and manned vehicles, could achieve a greater understanding of nature and himself.

Viewed objectively, space flight is inherently an international endeavor. Beyond the thin shield of the earth's atmosphere lies limitless space which has no national boundaries. The minds of educated men all over the world are being stirred at an increasing rate in the realization that exploration and research in space are about to begin. The tools and vehicles for this accomplishment are already at hand.

Only a few countries have the technical and production capabilities to commence this exploration at this time. But the minds of all men are stimulated by this thrilling prospect.

Brilliant scientists and engineers in all countries would like to study, work, and become identified with the evolution of astronautics. The absence in many nations of the all important rocket launching vehicles needed to carry instruments into space in sounding rockets and satellites is causing a natural frustration. This frustration, because of human nature, can lead to envy and bitterness.

The United States is currently engaged in setting up a national agency to administer and direct a space flight program.

What I would like to urge is this: that due consideration be given to the many advantages which would accrue to this country, in particular, and to the advancement of science, in general, by wide international cooperation with other nations in space flight research.

Accordingly, I would urge that the United States assert its leadership in welcoming the ideas and efforts of foreign scientists and engineers in the planning and execution of space flight projects.

To this end, I suggest that the following programs be established in conjunction with any national space agency:

1. A program to collect and disseminate information regarding plans and progress of the United States space flight program, as well as those of other countries.

The material to be disseminated would be written for both popular consumption as well as for the scientifically and technically educated. Such material might well take the form, initially, of quarterly bulletins as well as specific reports on particular projects. It is suggested that dissemination should be in English, French, German, Spanish, Italian, and Russian.

The United States Information Agency and the International Astronautical Federation, with its representative member societies in 21 nations, would seem to be appropriate agencies to cooperate in this work.

It is suggested further that close liaison be established overseas in the administration of such a program with the Advisory Group for Aeronautical Research and Development (NATO); USAF Air Research and Development Command office in Brussels, Belgium; the Office of Naval Research Liaison Office at London, England; the United States Army Research and Development Liaison Group in Frankfurt, Germany; and the Science Attaché program of the State Department.

2. The establishment of a significant number of graduate level scientific research scholarships with credit for advanced academic degrees.

Such scholarships should be on a funded basis, based upon international competition as well as, perhaps, on an exchange basis.

Nonsecurity-classified research would be conducted on instrumentation for use in sounding rockets and satellite vehicles, as well as design and engineering concepts for manned and unmanned space flight.

All scientific disciplines should be covered including social and legal aspects.

Funds would be provided to cover transportation, tuition, and at least minimum living costs.

It might be expected that the aviation and guided missile industry would sponsor a number of such scholarships.

3. A continuing program of international competition with regard to experimental research to be conducted in United States satellites.

The choice of experiments to be performed in United States satellites to date has been solely from the proposals from United States scientists. I am certain that the opportunity of foreign scientists to play a part in satellite research would bring hundreds of new scientific minds to bear upon the subject.

In this program, foreign scientists would study and recommend, not only the kind of measurement to be performed, but also suggest measurement techniques and instrumentation design.

It is folly to think that we have in this country a corner on the brains market. If, at the outset of the Vanguard program, the United States had set aside 1 of the 6 planned satellites to be instrumented in accordance with the results of an international scientific competition, I submit that the world reaction to the early Vanguard launching failures would have been one of shared sympathy and compassion rather than the gloating that occurred.

4. I propose that the United States take the initiative and, through the United Nations, call for an "International Conference on the Peaceful Applications of Rocket Power."

Such an international conference would affirm United States interest in rockets for peace, just as 3 years ago we took the initiative and called for an atoms for peace conference.

The International Astronautical Federation would be of great assistance in the organization and administration of this conference under the advice and assistance of the United Nations.

It is generally accepted among nuclear physicists that the Geneva Atoms for Peach Conference was healthy and aided greatly in dissemination of information and in the stimulation of new ideas. I am certain that similar results would accrue from a rockets for peace conference.

In summation, I am convinced that the establishment of the above program would assert the leadership of the United States and affirm our appreciation of the international aspects of astronautics.

The United States did assert this leadership on July 29, 1955, when President Eisenhower announced the establishment of the United States satellite program for the International Geophysical Year. But, to maintain leadership a continuing program of contact, liaison, and dissemination is necessary.

This country is not recognized currently as displaying leadership in astronautics. Precious time is being lost. The educated world is hungry for easily obtainable factual information. Foreign scientists and engineers crave an opportunity to participate in space research. The youth in this country and abroad yearn to become knowledgeable in astronautics so that they can appreciate and taste fully the fruits of space research in the next decade.

Finally the United States has the opportunity to become a leader in astronautics and to share with other nations our plans and programs for space research. The return benefits which could accrue to the United States would be positive and widespread; not only from a scientific and technical standpoint, but from the respect and enthusiasm we will elicit for sharing with others our astronautical heritage.

In thus asserting leadership by extending a friendly invitation to cooperate, a first step will be made along the way to possible future partnership in space projects on a global basis.

It is envisioned, hopefully, that cooperation at some future date may be extended to equipping and staffing of tracking and communications stations, as well as to the funding and production of international space vehicles.

At some point in the years ahead, it will become highly inefficient not to cooperate because of the magnitude of cost of large astronautical projects, such as flights to the planets.

A first step has to be taken by some nation. I hope it will be the United States.

Thank you.

(The documents submitted by Mr. Durant follow:)

COMMISSION ON ASTRONAUTICS, ACADEMY OF SCIENCES, U. S. S. R.[1]

(F. C. Durant III)

The bold accomplishment of satellite flight by the U. S. S. R. did not spring from short-term intensive effort. Nor was it dependent upon scientific breakthroughs, superfuels and metals, or new sources of power. The Russian achievements were the product of a coordinated program, planned by a group of competent scientists comprising the Commission on Astronautics of the Academy of Sciences, U. S. S. R.

This body had the responsibility to organize the program, to assign the appropriate research tasks, and to see that this work was carried out. Their job was to identify the basic problems which had to be answered before scientific research satellites could be launched, and obtain the answers. They were eminently successful.

These men were not engineers. The tasks of design, production, logistics, and launching were left to the military. The controlling body, however, was the Commission on Astronautics.

The Soviet Academy of Sciences is an elite organization composed of hundreds of scientists assisted by practical experts and technicians. Membership to the academy brings a special stipend and great professional prestige. In essence it is the centralized body of control of all Soviet science. The interests of the Academy range from pure science through engine design to medieval history. In 1952 it had 40 commissions and committees, 14 museums, 4 observatories, 57 institutes, 38 research stations, and 15 laboratories. Through these and other agencies it directs the work of thousands of scientists and technicians throughout the Soviet Union. Policy and direction flow from the U. S. S. R. Council of Ministers through the Chief Scientific Secretary, appointed by the Communist Party. The current Secretary is A. V. Topchiev. The President of the Academy is a respected organic chemist, A. N. Nesmeyanov.

Because Russian science is under state domination, heavy-handed, unenlightened administration might easily stifle progress and creative talent. Evidence during at least the last few years, however, indicates that great care has been taken not to demand practical results too quickly but rather to assign requirements, responsibility, and authority and let the scientists run the show.

The Commission on Astronautics was officially established early in 1955 under the Academy's Astronomical Council. Its official title is "The Interdepartmental Commission for the Coordination and Control of Scientific-Theoretical Work in the Field of Organization and Accomplishment of Interplanetary Communication of the Astronomical Council of the Academy of Sciences of the U. S. S. R." The fundamental task of the Commission is "* * * to assist in every way the development of scientific-theoretical and practical work in the Soviet Union concerning questions of studying cosmic space and the accomplishment of astronautics."

The responsibilities and powers of the Astronautics Commission are specific and extensive. The Commission is charged with—

[1] Portions of this article were published in the December 1957 issue of Missiles and Rockets.

1. "Taking actions which secure the active participation of academic and branch scientific-research establishments in work for the investigation of cosmic space."
(Direct appropriate institutes and laboratories to earmark personnel and time for research on problems assigned by the Commission.)
2. "Organization of work on drawing up problem plans and programs of scientific investigations on the fundamental trends of astronautics." (Draw up a long-range development program and identify the important areas of ignorance to be investigated)
3. "Broad attraction of scientific-research establishments, of universities and individual investigators to the solution of problems to secure the realization of flight into cosmic space " (Sell astronautics as an exciting new field of research to the scientific fraternity.)
4. "Coordination of scientific activities of individual research institutions on the problems of astronautics " (Make certain that there is a horizontal flow of appropriate information between the various research institutes.)
5 "Popularization of the tasks and achievements in the field of astronautics." (Educate the population at various levels of intelligence in the technical feasibility of astronautics and the potential value of satellite and other space research.)

In addition, the Commission shall—

(*a*) Review the plans and reports of the "scientific research institutes which work on the program controlled by the Commission."

(*b*) Sponsor scientific conferences on astronautical problems.

(*c*) Serve as the award committee in stimulating the submission of scientific work in competition for the triennial K. E. Tsiolkowski gold medal, established in 1954

(*d*) Maintain, through the Foreign Section of the Academy of Sciences, contact with the scientific organizations in foreign countries which are concerned with high-altitude research and space flight.

The Chairman of the Commission on Astronautics is Academician L. I. Sedov. Sedov is a distinguished physicist who in the past has been known for his works in analytical mechanics and gas dynamics He presides over 26 other members who, currently, are (see tab A). By and large this is a distinguished group of scientists Many are leaders in their fields. Almost any United States scientist concerned with upper atmosphere research or astronomy will recognize some of the names.

For example, a leading Harvard astronomer told me recently that, in his opinion, V A. Ambartsumian is one of the world's top astronomers. Certainly Ambartsumian impressed those who heard him speak at the Cosmical Gas Dynamics Symposium at Cambridge, in June of this year.

N. P. Baravashev, an astronomer, is director of the Kharkov Observatory and well known for his book on the geophysics of the moon and the planets. In February of last year he was chairman of an important conference on the physics of the moon and the planets at Leningrad State University

A A Blagonravov is an armaments specialist and a member of the Presidium of the Academy of Sciences.

N N Bogolyubov is a mathematician well known for his work in applied mechanics (vibration theory), quantum mechanics, and field theory.

V F Bolkhovitinov is an aircraft designer who, among other achievements built the first turbojet airplane in 1942

D N Frank-Kamenetskiei is a physical chemist who has studied combustion flame phenomena.

V. L Ginzburg has written of the potential value of earth satellites in verification of the general theory of relativity.

Peter L Kapitsa is, of course, a nuclear physicist and a cryogenicist of international fame His place on the Commission is probably to backstop problems of low-temperature rocket propellents as well as to consider nuclear-rocket powerplants

A. G. Karpenko, the Scientific Secretary of the Commission, has written on the problems of temperature regimes of satellite vehicles.

M A. Lavrent'ev is a prominent mathematician.

A. G. Masevich is a woman astronomer in charge of the official tracking program for IGY earth satellites

D E Okhotsimskii is best known for his writings on rocket propulsion and the orbits of earth satellites.

P. P. Parenago is recognized as an outstanding astronomer known for his studies of electromagnetic phenomena.

Yu. A. Pobedonostsev is an oldtimer whose work and interest run back to the Russian Rocket Society (Mosgird) days of the early 1930's.

K. P. Stanyukovich is a noted Soviet physicist whose name is associated with aerodynamics and explosion phenomena.

A perusal of Project Rand's F. J. Krieger's excellent Casebook on Soviet Astronautics, parts I and II, indicates clearly that a substantial number of members of the Commission on Astronautics have been active in popularizing astronautics Through the medium of the press and various conferences, basic principles of space flight have been expounded.

One important announcement may be forthcoming in the next several weeks—the naming of the first recipient of the Tsiolkowski gold medal This award will be made "to Soviet and foreign scientists for original work of major significance in the development of astronautics." The closing date for this competition was April 1, 1957. It could be expected that the individual (or individuals) named will be those who have played key roles in the development of the first sputniks.

With the successful accomplishment of the initial steps in astronautics, the Commission on Astronautics is undoubtedly at work on the more obvious follow-on projects, namely:

(a) More and larger satellite vehicles;
(b) Recoverable satellites;
(c) Space medical research in satellites;
(d) Lunar impacting vehicle;
(e) Circum lunar vehicles.

That these projects are technically feasible is no longer a question. The question is, rather, how far along is the U. S. S. R. in their prosecution. If they are all accomplished in 1958, the United States will really have a hard time catching up, and a still harder time in beating the Soviets to later firsts in space research.

LIST OF MEMBERS OF THE INTERDEPARTMENTAL COMMISSION ON INTERPLANETARY TRAVEL OF THE ASTRONOMICAL COUNCIL OF THE ACADEMY OF SCIENCES, U. S. S. R.

1. Sedov, L. I., academician, chairman.
2. Petrov, G. I., corresponding member, Academy of Sciences, U. S. S. R., Vice Chairman.
3. Levin, B. Yu, doctor of physicomathematical sciences.
4. Lavrent'ev, M. A., academician, Mathematical Institute, Academy of Sciences, U. S. S. R.
5. Kapitsa, P. L., academician, Physical Laboratory, Academy of Sciences, U. S. S. R.
6. Bogolyubov, N. N., academician, Mathematical Institute, Academy of Sciences, U. S. S. R.
7. Blagonravov, A. A., academician, Mechanical Engineering Institute, Academy of Sciences, U. S S. R.
8. Ambartsumyan, V. A., academician, Academy of Sciences, Armenian, U. S. S. R.
9. Lebedev, S. A., academician, Institute of Precision Mechanics and Computer Engineering, Academy of Sciences, U. S. S. R.
10. Parenago, P. P., corresponding member, Academy of Sciences, U. S. S. R, State Astronomical Institute.
11. Ginzburg, V. L., corresponding member, Academy of Sciences, U. S. S. R., Physical Institute.
12. Trapeznikov, V. A., corresponding member, Academy of Sciences, U. S. S R., Institute of Automatics and Telemechanics, Academy of Sciences, U. S. S. R
13. Petrov, B. N., corresponding member, Academy of Sciences, U. S. S. R, Institute of Automatics and Telemechanics, Academy of Sciences, U. S S. R.
14. Frank-Kamenetskii, D. N., doctor of chemical sciences.
15. Khaikin, S. E., doctor of physicomathematical sciences, chief Astronomical Observatory.
16. Pokrovskii, G. I., doctor of technical sciences, Military Air Academy.
17. Vanichev, A. P., doctor of technical sciences.
18. Pobedonostsev. Yu, A., doctor of technical sciences.
19. Duboshkin, G. N., doctor of physics-mathematical sciences.
20. Stanyukovich, K. P., doctor of technical sciences, Moscow Higher Technical College, im. "Bauman."

25973—58——66

21. Bolkhovitinov, V. F., doctor of technical sciences, Military Air Academy.
22. Florov, Yu. A., leading constructor, TsIAM.
23. Barabashev, N. P., academician, Academy of Sciences, Ukraine S. S. R.
24. Masevich, A. G., candidate, physics-mathematical science.
25. Markov, A. V., doctor of physics-mathematical science.
26. Okhotsimskii, D. E., candidate, physicomathematical science.
27. Karkenko, A. G., scientific secretary of the commission.

(Signed) L. SEDOV.

THE INTERNATIONAL ASTRONAUTICAL FEDERATION (IAF)

F. C. Durant III

Why it was founded

The rapid development of military rockets during World War II was led to a growing public interest in rocketry and in the possible use of rocket power for the attainment of space flight. Flight outside the earth's atmosphere has been a dream of man for generations It has long been appreciated, from a theoretical standpoint, that rocket power is the key to flight into space, because it is currently the only feasible propulsion system not requiring the oxygen in the atmosphere for combustion. Rocket powerplants are completely self-contained.

The advancement of rocket technology during and since World War II, together with other advances in electronics, metallurgy, supersonic flight, and atomic power, has led professional scientists and engineers to a startling conclusion: Space flight might be achieved in their generation. The announcement of satellite vehicle programs is recognized as an important step in this direction.

Few of the pioneers of rocket power had in mind the use of rockets as weapons of war The realization of space flight and space research as a peaceful enterprise was more often their aim. Many experts in astronautics are convinced that the full appreciation of the potentialities of space flight is a scientific, technical, and economic problem of such magnitude that it cannot be solved by one nation alone; unselfish international cooperation is necessary.

The First International Congress of Rocket and Astronautical Societies was held in 1950 at Paris. Its purposes were to discuss the possibilities of merging the influence of national societies and to enlarge upon the efforts of these societies through an international exchange of experiences and ideas. Subsequent annual congresses have been held at London, Stuttgart, Zurich, Innesbruck, Copenhagen and Rome and Barcelona. Organizations from 21 nations are now members of the IAF. At all of these congresses, the delegates of the national member societies have been impressed by the excellent spirit of cooperation. Although the opinions of the delegations have occasionally differed on technical points, agreement has been reached on all important issues. This proof of harmony and fellowship augurs well for the young federation. The constitution as a working document and the activities of the officials, the council, and the member societies are important, but the cornerstone of the IAF is the element of good will among men of many nations.

The aims

The general aims and objectives of the International Astronautical Federation, as described in its constitution, are listed below: "The IAF shall exist to promote and stimulate the achievement of space-flight as a peaceful project.

"The IAF shall do all in its power to secure the widespread dissemination of technical and other information on space-flight through the medium of exchange of publications, collaboration on research, etc., as between its members.

"The IAF shall do all in its power to stimulate public interest in, and support for, the idea of space-flight through the medium of books, press, lectures, radio, films, etc.

"The IAF shall do all in its power to stimulate work on astronautical subjects by international and national research and development establishments, universities, commercial firms, individual specialists, etc."

Membership

The following organizations are current members of the IAF:

Argentina: Asociacion Argentina Interplanetaria, the University of Cuyo (affiliate member).

Austria: Oesterreichische Gesellschaft fuer Weltraumforschung.

Brazil: Sociedade Interplanetaria Brasileira.

Chile: Sociedad Interplanetaria Chilena.
Denmark: Dansk Interplanetarisk Selskab.
Egypt: Association Egyptienne Astronautique.
France: Societe Francaise d'Astronautique.
Germany: Deutsche Gesellschaft fuer Raketentechnik und Raumfahrt, Deutsches Raketen-und Raumfahrt-Museum e. V., Deutsche Arbeitsgemeinschaft fuer Raketentechnik.
Great Britain: British Interplanetary Society.
Italy: Associazione Italiana Razzi.
Japan: Japanese Astronautical Society.
Jugoslavia: Astronauticko Drustvo.
Netherlands: Nederlandse Vereniging voor Ruimtevaart.
Norway: Norsk Astronautisk Forening.
Poland: Polskie Towarzystwo Astronauticzne.
Spain: Agrupacion Astronautica Espanola.
Sweden: Svensk Interplanetarisk Selskap.
Switzerland: Schweizerische Astronautische Arbeitsgemeinschaft.
Union of South Africa: South African Interplanetry Society.
United States: American Rocket Society. American Astronautical Society.
U. S. S. R.: Commission on Astronautics, Academy of Sciences.

These national societies, excluding affiliates, comprise more than 11,000 members. A high percentage of the membership is made up of professional men representing all major fields of science and engineering technology. This wide variety of professions in an excellent demonstration of the fact that astronautics draws upon nearly every field of human knowledge. It follows, therefore, that cooperation in all of them is needed for the exploration of space to be achieved.

The IAF Council meets with delegates of member societies at the annual congresses. Besides IAF business, discussed in plenary sessions, several days are set aside for the presentation and discussion of technical papers.

Several administrative and scientific committees have been appointed by the IAF Council. Some of their activities include: liaison and cooperation with other international organizations; recommendations for standardization of astronautical nomenclature and library classification systems; a multilingual glossary of astronautical terms; and the publication of an international astronautical journal. Astronautica Acta. Each year, the Guenter Loeser Memorial Medal is awarded at the congress to the author of the paper adjudged most important.

A permanent secretariat, an archive, and an astronautical library are maintained at the IAF headquarters at Baden, Switzerland. An IAF bulletin is published regularly and sent to member societies.

The next congress will be held at Amsterdam, August 25–30, 1958. Further information may be obtained from: Ing. Josef A. Stemmer, Secretary, International Astronautical Federation, Post Box 37, Baden, Switzerland; or from the IAF officer nearest you:

President: United States: Mr. Andrew G. Haley, 1735 DeSales Street NW., Washington, D. C.
Vice Presidents:
United Kingdom: Dr. Leslie R. Shepherd, 28 Avon Road, Chilton, Berks, England.
Argentina: Ing. T. M. Tabanera, Tucuman 950, Buenos Aires, Argentina.
France: Gen. Paul J. Bergeron, 2, rue Voisembert a ISSY, (Seine), France.
U. S. S. R.: Prof. Leonid I. Sedov, Chairman, Commission on Astronautics, Academy of Sciences, Moscow, U. S. S. R.
Sweden: Ing. Åke Hjertstrand, Engelbretsgatan 12$^{\text{iv}}$, Stockholm, Sweden.
Poland: Prof. Kasimierz Zarankiewicz, Al. Wawelska 19 m. 20, Warsaw, Poland.

The CHAIRMAN. Now, as to any questions asked by the members of the committee, might I suggest they respond like a panel. If the other one agrees, just simply say "I agree." But if you disagree, in whole or in part, then express it at that time. Of course, you will have an opportunity of revising and editing your remarks.

If you want to enlarge on questions answered extemporaneously, you have permission to do so when you edit your remarks.

Mr. HAYS. Thank you, Mr. Chairman.

I would like to thank both our witnesses for excellent statements. They are quite consistent with each other on this emphasis on international cooperation.

I am confident that both Admiral Berkner and Mr. Durant will have an interesting response to this question:

To what extent are we now able to secure the cooperation of the Soviet scientists in our development of this program?

Dr. BERKNER. Mr. Hays, there has been substantial cooperation with the Soviet scientists in connection with the flight of the satellites. There has been release of information by both the United States and by the Soviet Union concerning the location of their satellites and, to some extent, concerning the scientific information acquired by the satellites.

On April 27, there was published in Pravda a very important review, of which I have a copy in teletype form here, of a scientific publication which has been released by Moscow. I have not yet received the original. This indicates a very extensive release by the Soviet Union of scientific data obtained during the operation of Sputnik I, and some information obtained during the operation of Sputnik II.

I invite your attention to the fact that the Pravda publication was sufficiently complete to give us a rather good insight into the principal scientific results which they obtained from the flight of those satellites.

Tomorrow morning, at the National Academy of Sciences, representatives of our National Academy will release certain scientific information that has been obtained to date. This United States information will be released by a panel of our leading satellite experts.

Consequently, I think it can be said categorically this morning that the interchange of scientific information on the subjects of satellite reseach is really in remarkably good shape.

Mr. HAYS. Have you discovered to any extent whether the Soviet Union scientists have been inhibited by military considerations in making the information available?

Dr BERKNER. They certainly have been in some respects. Their inhibitions have been very similar to our own inhibitions with respect to our launching techniques.

At the conference on rockets and satellites held in Washington last year, September 30 to October 4, the Soviets released full information on their so-called meteorological rocket. Their data included pictures and technical details of a rocket which is capable of flight and outer atmospheric research to an altitude of approximately 100 miles.

They announced at that time that they also had what they called a geophysical rocket that was capable of going 200 miles. I believe in recent flights this rocket has gone somewhat higher.

I asked the leader of that delegation, Professor Blagonravov, for technical information on this rocket. He said quite frankly it was not yet declassified. He hoped sometime in the near future to be able to provide the full information available on this type of rocket.

Mr. HAYS. It is generally true that, by temperament, scientists are eager to share information, their pursuit of knowledge carries with it a desire to give knowledge to others and, in turn, acquire knowledge from them?

Dr. BERKNER. Yes. I might add there may be a bit more pecuniary interest in the matter since as one acquires knowledge from others, he is able to extend the scope and effectiveness of his own theories.

Mr. DURANT. I might like to add one point.

In addition to the channel of communication built up in the IGY through the national committees, which is what Dr. Berkner was referring to, I believe, another channel has been established through the International Astronautical Federation. In 1955, the first Russians came to our annual conference.

In 1956, the Commission on Astronautics of the Academy of Sciences at Moscow joined the federation.

Last year, 1957, there were four papers presented at the Barcelona Conference, which followed immediately after the meeting Dr. Berkner referred to, and it is another channel.

Professor Sedov was the Chairman of this Commission and attended all these meetings.

The IAF is another channel of communication. Since Professor Sedov has accepted one of the vice presidencies it is hoped that this additional channel can be enlarged and strengthened.

Mr. HAYS. Again, from the scientists' standpoint, we have every reason to believe that with the firming up of peace conditions, so that world tensions may be relaxed, fears dissipated, there will be a tremendous impetus to the sharing of scientific knowledge. That is one goal that the scientists would earnestly seek for; is it not?

Dr. BERKNER. Mr. Hays, certainly within the limits of security classification set up by each nation for its own security, one would hope that full and free interchange of information might take place.

I might add that when one looks at the general properties of the present Government of the Soviet Union, one supposes that the improvement of exchange of information will inevitably soften the attitude of the Soviet Government which seems to be very hard in some respects at the present time. In the field of science I believe one can say that these attitudes are softer than they are in any other field in which we deal in with the Soviet Union. This, I believe, is an important factor in the relief of tensions.

Mr. HAYS. Generally speaking, is it true that the Russian scientists are not particularly interested in the political ideological basis of the Soviet Government's structure? In other words, they are not involved on the whole, are they, in the political life of the Soviet system?

Dr. BERKNER. Mr. Hays, that varies from individual to individual. Many of the Soviet scientists are almost totally free of any strong political feeling. On the other hand, without question, there are some scientists whom I know, who are confirmed Communists and who are strong upholders of the Communist social and imperialistic ideology.

Mr. DURANT. My experience and contacts support this view.

Mr. HAYS. That shows up in their scientific performance?

Dr. BERKNER. It certainly does.

Mr. FULTON. It varies also from field to field. In the fields of biology and genetics there has been a complete switch-about by the Russians.

Dr. BERKNER. That is true. We don't know how complete this switch-about is.

Lysenko is seated in a position of considerable authority in the Soviet Union. Vavilov has not again appeared on the scene. Yet there is an indication that, by force of necessity, the correct interpretation of scientific results is an essential to the growth of any part of the Soviet activities. The truth in science must be accepted by the Soviets as well as by free people.

Mr. HAYS. There is no evidence of switch-about, then, in the field of space, basic research and earth-satellite exploration?

Dr. BERKNER. As nearly as I can tell, they are doing a solid job. In studying this release there is every reason to believe that it is absolutely correct in every detail. It contains much useful information to us, sir.

Mr. HAYS. Admiral Berkner, I would like to have that release as a part of the record.

Dr. BERKNER. I have already given it to the counsel, Mr. Hays.

Mr. HAYS. Without objection, the release will be made a part of the record, Mr. Chairman.

The CHAIRMAN. The release, without objection, may be made a part of the record.

(The material referred to follows:)

U. S. S. R. NATIONAL AFFAIRS

APRIL 29, 1958.

FIRST SPUTNIK RESULTS PROVE VALUABLE

Moscow, Soviet Home Service, April 27, 1958, 0700 GMT—L.

(Material from Pravda: "The Soviet Artificial Earth Satellites—Some Results of Scientific Research on the First Two Soviet Artificial Earth Satellites.")

(Text:) The successful launching of the first artificial earth satellites marks the beginning of man's penetration into cosmic space. The artificial satellites open up the widest prospects for many very important scientific research projects. Great scientific and practical interests are presented by the study of the ionosphere and the mechanism of its foundation, the influence of the radiation of the sun and cosmic rays on the earth's atmosphere, the study of the density and temperature of the magnetic and electroscopic fields at great heights, and so on.

The solution of these problems demands carrying out direct experiments at heights of hundreds and thousands of kilometers from the surface of our planet. The chance of carrying out such experiments appeared with the creation of the artificial satellites, with the necessary scientific measurements to be taken at great heights over various areas of the earth over a prolonger period.

Only after the building of intercontinental ballistic missiles in the Soviet Union was it possible for the first time to launch an artificial earth satellite. The outstanding qualities of design in this rocket enabled satellites with a heavy load of scientific apparatus to be put into an orbit. The launching of the earth satellites with heavy loads of scientific apparatus enables complex series of scientific research projects to be carried out; and the fact that they are carried out simultaneously greatly increases their scientific value. Only by launching large artificial satellites is it possible to solve the problem of creating permanently operating cosmic laboratories, for realization of interplanetary flights.

The first Soviet artificial earth satellite was put into an orbit with a perigee—the nearest point of the orbit to the earth—of 228 kilometers and an apogee—the farthest point of the orbit from the earth—of 947 kilometers.

In the case of the second satellite, the corresponding figures were 225 and 1,671 kilometers, respectively. The time of revolution around the earth at the beginning of the flight was 6.17 minutes for the first satellite and 103.75 for the second.

During the satellites' movement along orbits at the aforementioned range of heights, it was possible to carry out research on study of the upper atmosphere,

determination of the density of the atmosphere, study of the diffusion of radio waves, and so on. On the other hand, density of the atmosphere at these heights is sufficiently thin, and therefore the measuring of primary components of cosmic radiation, the spectrum of the short-wave radiation of the sun, and so on was not distorted.

Scientific tasks have also determined the selection of the angle of the orbit to the plane of the earth's equator, of approximately 65°. The advantage of such an orbit is that when the satellite goes into orbit, the installed scientific apparatus can take measurements over various latitudes It is worth noting that putting a satellite into an orbit at a greater angle to the Equator is a far more complicated task than putting it into an orbit close to the Equator's orbit.

During the period of its existence, from October 4, 1957, to January 4, 1958, the first Soviet satellite made 1,400 circuits around the earth. The second satellite completed about 2,370 circuits from November 3, 1957, to April 14, 1958. With the aid of the first Soviet artificial satellites, the outlined program of scientific research was carried out successfully. A few preliminary results of the research are given below. On the whole, the accumulated information is very extensive, and work is continuing on it.

Radiotechnical and optical observations of the artificial earth satellites

Insofar as analysis of the change in the orbit of the satellite in time makes it possible to assess the density of the upper layers of the atmosphere, there is great significance in the study of the movement of the satellites. The elements of the orbits of the earth satellites can be determined on the basis of observations carried out by radiotechnical and optical methods. Among the radiotechnical methods used were radio position finding and the observation of the Doppler effect during reception of radio signals from the satellite.

The Doppler effect is as follows: Upon the approach of the object carrying the radio transmitter to the radio reception point, the frequency of signals received is increased and upon the object's moving away it is reduced.

The change in frequency depends on the speed of approach and recession. Under conditions of the satellites' flights, the speed of approach and departure of the satellites over the radio receiver were so great that the Doppler effect, which permits observation on a normal radio receiver, could be used to register the moment of the satellite's passing at its nearest point to the observation center, and also to define the distance to the satellite and its speed.

During radio observation of signals from the first and second satellite, the measurement of the frequency of radio signals received took place; for this purpose, a special radio apparatus and a recording chronograph were employed. In order to increase accuracy, measurements of the signals were taken on a frequency of 40 megacycles, a frequency least subject to influence from the ionosphere. The power of the transmitters insured certain reception of the signals over a field of direct visibility. Thus, in 24 hours it was possible to observe 6 to 7 consecutive passages of the satellite over land stations.

In order to process the radio signals received, the moment of the satellite's passage at the shortest distance from the observation point was defined with a tolerance of one-tenth to two-tenths of a second. The observations that have been carried out show that the Doppler effect can be used successfully to define the parameters of the satellites' orbit. The value of this method lies in the simplicity and reliability of the apparatus. With the rise of the frequency of the transmitter carried by the satellite, and with employment of schemes of automatic measuring of frequency, mistakes in this method can be substantially reduced.

For a more precise determination of the coordinates, special photographic theodolites (fotokinoteodolites) were used, and modernized aerial photography cameras were used for photographing the satellite's path. During the photography, the timing was set with the aid of a number of consecutive openings and closings of a shutter, involving the registration of the time of these operations by a photoelectric method. Thus, an interrupted trail of the satellite appeared on the photograph. Great accuracy was achieved in using these cameras.

Determination of the density of the atmosphere

Even before the launching of the first artificial satellites, the possibility of determining the density and temperature of the atmosphere through observation of their movements was noted. During movement through the earth's atmos-

phere, the artificial satellites met with resistance. The strength of the resistance is in proportion to the density of the atmosphere.

As a result of the breaking influence of the atmosphere, a gradual reduction in the height of the orbit of the satellite takes place. This continues until the satellite enters the dense layers of the atmosphere and ceases to exist.

The density of the atmosphere falls quickly, the further one gets away from the earth's surface, and the resistance force in different sectors of the elliptical orbit is not uniform. In a sufficiently extended orbit, the resistance force of the perigee is much greater than that of the apogee. Therefore, the main braking effect takes place in the perigee. This characteristic of intermittent braking means that reduction in height of apogee of the orbit takes place considerably faster than the reduction in the height of the perigee. The evolution of the satellite's extended orbit thus results in its form gradually becoming circular.

After launching of the first and second artificial satellites, optical observations and radio observation enabled the evolution of their orbits to be followed. On the basis of a theoretical analysis of results of these observations, it has been possible to determine these values as the product of atmospheric density times the square roots of the altitude of a homogeneous atmosphere, at the perigee altitudes of 225 to 228 kilometers of the first satellites.

On the basis of certain hypotheses on the height of the uniform atmosphere, the values (znacheniye) for the density have been calculated. The values obtained were 5 to 10 times greater than the values indicated for these heights, in a number of studies of the atmosphere based on rocket measurements prior to the launching of the satellites. It is worth noting that determination of the density of the atmosphere, and the study of purely mechanical influence of the atmosphere on the satellite are extremely accurate The atmosphere of the earth over different areas of its surface is not uniform. At the same height, the density and temperature changes according to the latitude and the time of day This is all related to the unequal heating of the upper atmosphere with ultraviolet, X-ray, and corpuscular radiation from the sun

As a result of the fact that the gravitational field of the earth differs from the central field, the orbits of the artificial satellites changed their situation in space. Thus, for the first satellites, the angular distance of the perigee from the midday meridian changed by approximately 4°, while the latitude of the perigee changed by 0.35° per 24 hours.

On the basis of data received, it would appear that the temperature of the atmosphere at heights around 225 kilometers is greater than previously supposed on the basis of theoretical considerations.

The discovery of the high temperature of the atmosphere confronts geophysicists with the problem of the sources of energy and its high heat capacity. The well-known "hard" ultraviolet and X-ray radiation from the sun will hardly suffice to explain this.

At present, it is possible to put forward hypotheses on this question. One could assume, for instance, that the upper layers of the atmosphere in polar areas are heated intensively by the corpuscular radiation from the sun. It is also possible that the entire upper atmosphere is receiving extra heat from either infrasound waves from the troposphere, or by electric current arising in the conductive ionized air as a result of its movement in the earth's magnetic field. The further study of the upper atmosphere with the aid of rockets and artificial earth satellites will make it possible to find a final answer to all these interesting and important questions

The results of research in the ionosphere

The observation of radio signals received from the first artificial earth satellites has provided new data on the outer part of the ionosphere—above 300 to 400 kilometers The ionosphere is the upper part of the atmosphere, consisting of a considerable number of free, charged particles, electrons and ions. When radio waves pass through the layers of ionosphere, the phenomena of their reflection, their partial and complete absorption, and the distortion of their routes occur. For this reason, radio methods have become the most effective means of carrying out research into the upper layers of the atmosphere.

In the reception of radio signals from the first artificial satellites on a frequency of 40 megacycles, it was possible in a number of cases to observe, free from distortion, the appearance and disappearance (radio-voskhod i radiozakhod) of the satellite's radio signals, and note the exact time. In contrast to the optical appearance and disappearance of the satellite, determined by the fact that the light rays pass to the observer from the satellite in a straight

line, in the case of radio appearance and disappearance, the radio rays are distorted in the ionosphere.

The data obtained from reception of radio signals from the first artificial earth satellites makes it possible to assume that the electron concentration in the other ionosphere, at a greater height than the main maximum, falls off with the altitude 5 to 6 times more slowly than it increases below the maximum. Thus in the 100-to 300- kilometer range, the electron concentration increased tenfold during the period of observation in October, while in the 300- to 500-kilometer range, it decreased twofold.

Research into cosmic rays

Two instruments registering the number of particles in radiation were installed in the second artificial earth satellite for the purpose of research into cosmic rays. In its flight around the earth, the satellite orbited at varying distances above its surface. Therefore, the measuring of cosmic rays on the satellite made it possible to define the independence of the number of particles on the height.

The data obtained have shown that from the minimal orbit height of 225 kilometers to a height of 700 kilometers, the intensity of cosmic radiation increased by about 40 percent. This increase was conditional, primarily on the circumstance that the greater the height, the less the shielding of the earth, the cosmic rays thus being able to reach the instrument from a greater number of different directions.

The earth's magnetic field also creates an obstacle in the way of cosmic rays reaching the earth. The study of cosmic rays with the aid of the apparatus installed on the satellite can also provide information on the dependence of the intensity of cosmic rays on latitude and longitude. This enables fresh information on the earth's magnetic field to be obtained. The measurement of the magnetic field over the earth's surface enables some picture of the character of the earth's magnetism to be formed, making it possible to forecast what kind of magnetic field should obtain at great distances from the earth.

In this way, it is possible to calculate the expected distribution of intensity of cosmic rays along the surface of the earth. In particular, it is possible to point out the lines of constant intensity of cosmic rays, the so-called isocosmic lines (izokosmy). The measurements of cosmic rays carried out during the flights of the satellite showed that the lines of constant intensity derived from the experiment and those calculated in theory, differ substantially.

This result is in accordance with the conclusions of the physicist Simpson, who arranged a large series of flights of high-altitude aircraft in equatorial areas. They showed that the equator found with the aid of cosmic rays does not coincide with the geomagnetic equator.

Consequently, there is a considerable difference between the characteristic of the earth magnetism—the magnetic field—obtained on the one side with the aid of cosmic rays, and those obtained by means of measurement of the magnetic field on the surface of the earth

These differences are explained by the fact that the trajectories of the movement of cosmic rays are determined by the magnetic field at very high altitudes, while the direct measurements give characteristics of the magnetic field near the surface of the earth. Cosmic rays permit probing of the magnetic field at great distances from the surface of the earth, giving an opportunity for a new approach to the study of the magnietic field of the earth and the system of electric currents in the upper layers of the atmosphere.

The observation of cosmic rays by the earth satellite made it possible to register the fluctuations of the intensity of radiation. These variations are evidently connected with the state of interplanetary space near the earth. One case of a sharp increase—50 percent—in the number of the particles of cosmic radiation was registered. At the same time, the ground stations did not discover at that time any substantial increase in the intensity of cosmic radiation. This event is now being studied in detail. It is thought that it was due to generation in the sun of particles of low-energy cosmic rays, which are strongly absorbed by the earth atmosphere, or due to the earth satellite passing through a stream of electrons of high energy connected with the corpuscular radiation of the sun. These phenomenums could not so far be registered, because the instruments for the (word indistinct) observation of cosmic rays were situated on the surface of the earth. The artificial earth satellites have for the first time allowed full research to be carried out in primary cosmic radiation.

Biological research

It was possible to carry out a biological experiment under cosmic flight conditions only in an artificial earth satellite. First of all it dealt with the study of the effects on a living organism of a prolonged condition of weightlessness, primary cosmic radiation, certain types of solar radiation and other factors. The data obtained when the program of medical and biological research was carried out in the second artificial earth satellite is of great value.

As is well known, the dog, Laika, took a cosmic flight in the satellite. Of great interest is the behavior and the state of the animal during the most difficult stage of the flight of the satellite from the biological point of view—in the time of its launching and its going into the orbit. The movement of the satellite while it was being placed in orbit was accelerated, and the ratio of acceleration exceeded by many times the force of gravity on the surface of the earth. At the same, the apparent weight increased in proportion to the increase in acceleration.

During the time the satellite was going into orbit, the position of the animal in the satellite was such as to experience the effect of acceleration from the breast to the back, and in this case the force of the acceleration pressed the animal to the floor of the cabin. This position of the animal was chosen because it was one of the most convenient for living organs. While the satellite was being brought into orbit, the animal was affected by vibration and noise of the engine of the rocket, in addition to the effects of acceleration. The behavior and the state of the animal during the period of time that the satellite was brought into the orbit were adequately recorded.

From information obtained, it is possible to establish that up to a certain increase in acceleration the animal stood up to the seeming increase in the weight of its body and kept the freedom of movement of its head and trunk. Then it found itself pressed against the floor of the cabin, and there were no noticeable movements recorded. The decoding of the data received from the satellite show that immediately after the start the rate of heart contractions increased approximately threefold. The analysis of the biocurrents of the heart on the electrocardiogram did not reveal any signs of ill effects, giving only a typical picture of the speeding up of palpitations, the so-called sinus tachycardia.

Later, when the effect of acceleration not only continued but grew stronger, the speed of heart beats decreased. It is easy to imagine that in accord with the increase in the apparent weight of the animal the breathing motion of the thorax became more difficult. Breathing became more shallow and frequent. In fact, the recordings of the telemetric signals have shown that when the satellite was brought into orbit the frequency of the breathing of the animal exceeded the original by 3 or 4 times.

There are grounds for believing that the changes noted in the state of the physiological functions of the animal were due to a sudden effect of sufficiently strong outside irritants on the organism—the acceleration, noise, and vibration which began during the start and continued during the period of the satellite's coming into orbit. Analysis and comparison of data obtained with the results of previous laboratory experiments permits the assertion that the animal endured quite satisfactorily the flight from the start of the satellite until it was brought into orbit.

After the satellite went into orbit, the centrifugal force which acted on the satellite had balanced the force of gravity of earth, and the state of weightlessness came into being.

There, the body of the animal stopped pressing against the floor of the cabin, and owing to contraction of the muscles of the extremities, was easily pushed away from it. Judging by the available recordings, these movements were not of very long duration, and sufficiently smooth. In connection with the fact that the thorax of the animal did not experience any more pressure under the influence of an increased weight, the frequency of breathing decreased.

After a very short period of increased palpitations, the frequency of the heartbeat continued to decrease, and to approach normal. However, the period of time during which the heartbeats reached their normal level proved to be approximately three times longer than the period in laboratory experiments, when the animals were subjected to the effects of the same accelerations as those when the satellite was sent into orbit. This is probably due to the fact that after the effect of acceleration had ceased, the animal, during the tests made on the ground, found itself in normal conditions, while in the satellite the accelerated motion changed into a condition of complete weightlessness.

In conditions of weightlessness, sensitive nervous centers of the animal which signal the position of the body were not sufficiently affected by external irritants. This caused fluctuations in the functional state of the nervous system which regulates breathing and blood circulation, and was responsible for the somewhat longer period that these functions took to return to normal again after acceleration had ceased.

The normalization of functional indexes of blood circulation and breathing in a state of weightlessness—during the satellite's revolutions in the orbit—however, by no means prove that this factor failed to cause any substantial and lasting changes in the state of physiological functions of the animal. One can thus say that not only during the satellite's being placed in orbit, but also in the course of its movement along the orbit, the animal behaved satisfactorily.

It was, however, impossible to form any definite idea of the effect of cosmic radiation on the test animal. No obvious physiological effect was directly observed. In order to carry out detailed research into this question, it is essential to observe the animal for a long period after the flight. This will be done in further experiments. The first assessment of the results obtained clearly shows that animals behave satisfactorily in the conditions of cosmic flight. In this light, the positive results of the experiment make it possible to continue and expand research aimed at safeguarding the health and life of man in cosmic flight.

The study is continuing of the large body of scientific evidence obtained with the first Soviet artificial earth satellites, both in the course of experiments described in this article and in other experiments carried out with the aid of the first satellites. Further launchings of satellites during the International Geophysical Year will make it possible to extend the scope of most important scientific experiments carried out in outer space, and to gain greater insight into a series of processes taking place in the upper layer of the atmosphere and in the cosmos.

(Editor's Note: TASS, Russian, at 0258 GMT, April 27, summarizes the article and adds that "preliminary results will be published in the near future in the form of scientific articles in different magazines.")

"Stationary" Satellites

Moscow, TASS, Radioteletype in Russian to Europe, April 23, 1958, 2207 GMT—L.

(Text) Kiev—The launching of an "immobile" earth satellite is a possibility, according to Nikolay Barabashov, a member of the Ukrainian Academy of Sciences in the Rabochaya Gazeta. The term "immobile," the academician writes, is not quite exact; it would be more correct to call it "stationary."

The stationary satellite can be created by launching into interplanetary space over the equator a body which, after having gone into the orbit, will move from west to east with a speed equal to the angular speed of the revolution of the earth around its axis. As a result of such launching, the satellite will always stay above a definite point of the earth's surface. The linear speed of the flight of the satellite must equal 3,076 meters per second. It has been calculated that it must stay at a height of 35,000 kilometers above the equator.

It is possible, the scientist continues, that when a certain level of development of stratoaviation is reached, the stationary satellite launched into stellar space may be used as a changing post, to which it will be possible to fly at any time without waiting for it to take up a definite position in relation to the flying field on earth. By launching three stationary satellites and placing them at distances of 120 degrees from each other along the orbit, it will be possible to observe the entire globe except for the polar zones, because the satellites will be placed in the plane of the equator.

Mr. Hays. I would like to ask you about the situation with reference to other nations, including the Iron Curtain countries. What do you know about the activities in Red China, for example, in this field?

Dr. Berkner. We know relatively little about the activities of Red China. We have some information which indicates that they are entering into a program of observing the Soviet satellites in cooperation with the Soviet scientists.

The Red Chinese originally adhered to the International Geophysical Year. Then for political reasons, probably because of the adherence of the Nationalist Chinese to the IGY, the Red Chinese decided to withdraw.

They are the only nation which has withdrawn for political reasons. All other nations have laid politics aside on the grounds that adherence to genuine scientific enterprise should have no political implication of any kind.

Mr. HAYS. Then in the free world association of scientists you have, perhaps, complete congeniality and free discussion. Is that correct?

Dr. BERKNER. That is correct, and to a substantial extent with respect to the Soviet Union and to the Soviet satellite states.

I think the discussion of unclassified scientific information has been rather full and complete with all nations excepting only Communist China.

Mr. HAYS. Mr. Durant got down to specifics on the United States taking a lead in the establishment of an international agency in this field. I assume you share his views. The tone of your statement would indicate you are in full accord with him.

Dr. BERKNER. We might debate the detailed character of such an agency, but I do not think that is important at this time.

The objective is one on which we certainly agree. It is quite evident that only a few nations, perhaps only two, the United States and the Soviet Union, can afford to enter into operations in space. It is clear that there will be great frustration on the part of individual scientists of other countries if they find it impossible because of their nationality to enter into some sort of space activity.

We certainly have much to benefit by encouraging such scientists to join into our activities.

Mr. DURANT. I am pleased to have Dr. Berkner's support on my suggested program. The method of implementation is secondary.

Mr. HAYS. Do you share his views that the cost will be insuperable without some help from other nations?

Dr. BERKNER. I do not believe the cost will be insuperable without help, but it would be less and, of course, we are all taxpayers.

Mr. HAYS. I do not recall he said they were insuperable, but you do share his concern about the cost of an adequate and comprehensive space program?

Dr. BERKNER. Yes. Certainly one can look at this two ways. Either the cost of a given program can be substantially reduced by accepting the cooperation of our fellow scientists in other countries, or to look at it on the other side of the coin, it will be possible to do much more space research than would be possible by trying to do it alone.

Mr. DURANT. I believe, Mr. Hays, that the term "insuperable" is not correct. I did refer in my closing statement to the fact that at some time in the future long-range, large-scale astronautical exploration will take place. At that time the costs of such programs probably could not be supported by one nation. From the standpoint of efficiency international cooperation would be highly desirable.

However, in the meantime, cooperation with tracking stations in scientific research can be done.

Mr. HAYS. We will use the words "substantial cost."

Mr. DURANT. Very good, sir.

Mr. HAYS. I would like to ask you both to comment on this:

I was in Moscow last week. While I gathered no information in this field that is not available to the general reader of documents coming out of Russia, I was interested in a side comment by one of the Russians as we passed a very imposing building. It was evident there was great pride in the fact that this building was one of their academies of science and the Russian added proudly, "We have several."

There is no question, is there, about the great interest being taken in the Soviet Union in this field?

Dr. BERKNER. There is no doubt about this, Mr. Hays. We must remember that the very foundation of Marxist ideology rests on the belief that science, and the materialism emerging from science, exploited by a Marxist government, would bring about the results for which they hope.

Therefore, from the very beginning of the present Soviet regime they have put tremendous emphasis on science. This is now beginning to pay off. This year, I believe, they passed us in the total number of scientists and engineers active in the Soviet Union. As nearly as we can estimate, these men are very well trained, extremely capable men in every sense.

Mr. DURANT. I concur with Dr. Berkner's views.

Mr. HAYS. Of course, we in the free world have a valid point in reply to that in this international competition, namely, that it is at expense of moral and spiritual values.

In other words, in applying our judgment of value to the Soviet world, we are saying that this great divergence of interest and this neglect of the moral and spiritual values has brought them that advancement at great cost. That is a philosophical observation.

Dr. BERKNER. Yes, Mr. Hays. I think our attitude among American scientists would be that an equivalent effort in the field of science will be necessary to maintain our position in the world competition. But that this certainly can and must be done with the full recognition of the other values that Americans hold highly—freedom, the spiritual values, the moral values, the ethical values—values that western culture generally regards very highly.

Mr. DURANT. I concur with Dr. Berkner.

Mr. HAYS. I have never detected in the disciplines of the American scientists, and I am speaking of physical scientists, any other feeling than that, that our progress in the field of science, physical science, must be matched by a comparable appreciation of the purpose of life and the purpose of discovering truth.

I mention this not because anyone needs convincing, but in the record it seems to me it should bear reiteration that our excitement over the great new field of endeavor is not to overshadow our appreciation of these basic purposes of life.

Dr. BERKNER. This is certainly something to which all Americans could subscribe.

I might add that I would hope and believe that the satellite and space exploration generally adds not only to our technical knowledge, but will add considerably to our philosophy, art, literature, poetry, humor, and to appreciation of human endeavor generally.

I see that my old friend, Mr. Fulton, is reading a book on exploration of space by Clarke which incidentally was written in 1951. It still is an entertaining and useful book on this subject.

Mr. FULTON. I hope that our perspicacity that you commented on in this committee equals your perspicuity.

Mr. HAYS (presiding). Mr. Natcher.

Mr. NATCHER. The bill before the committee establishes and creates a National Astronautics and Space Agency. Under the provisions of this bill we have a Board of not to exceed 17 members. The Director is to be named by the President and confirmed by the Senate.

There are a number of other important provisions in this bill.

What suggestions do you gentlemen have concerning any matter or any portion of the bill that should be changed in order that we can carry out the purpose that we have in mind?

Dr. BERKNER. Mr. Natcher, I have given the matter of organization a great deal of thought in preparing this testimony. It seems to me that we must remember that the Agency will be primarily concerned with research.

The operations that it conducts will be operations which are conducted primarily in support of research.

Therefore, I have asked myself the question whether I thought a commission form of administration, such as that of the Atomic Energy Commission, or the present Board-Director type of operation, such as that now used in the NACA, would be best.

First of all, it is my feeling that if the Agency becomes ingrown—primarily a monopolistic type of Government agency—the United States would lose very badly by such arrangement. It is quite clear, from experience gained from our present satellite programs, that science from universities, from industry, and from American institutions generally, must join with the Space Agency if its operations are to be effective.

I would very much doubt that one could ever assemble a sufficient staff within the agency to be competent to carry out all the research needed to keep America on the forefront of space science.

Therefore, I reach the opinion that in order to maintain close contact with what I would call the academic side of space activity, so that we can reach the scientists and the engineers and the men who are most likely to contribute most creatively to our progress in space, that it would be best to have an advisory board of the kind we have in the National Science Foundation, for example, with a strong director, very similar to the present form of administration in either the Science Foundation or the National Advisory Committee for Aeronautics.

Mr. NATCHER. Mr. Chairman, at this point I yield to Mr. Feldman.

Mr. FELDMAN. I just wanted to clarify something. Dr. Berkner, under the administration proposal the Board itself becomes an advisory board where previously it was the executive board. Now, the only thing it can do is advise. The Director does not have to take that advice.

Would that, in any way, modify your last answer?

Dr. BERKNER. I rather think that a wise Director, one which would be confirmed by the Senate, would be a man who would heed the advice of the Board very carefully. One would suspect that if there were sharp differences of opinion between the Board and the Director that these would be examined most carefully.

On the whole, from a policy point of view, I prefer to see the type of organization that we traditionally have in American industry and

in American education over which one has, if you like, a board of trustees and a president or managing director.

Mr. FELDMAN. Would you make that Director a member of the Security Council?

Mr. BERKNER. I would leave this, I believe, to the discretion of the President.

Mr. NATCHER. Am I to understand that you gentlemen agree with section 4 of the bill providing for a Board of not to exceed 17 members? Do you agree that that type of setup in this particular legislation is proper?

Dr. BERKNER. I would recommend it, sir, as proper.

Mr. NATCHER. Do you both agree?

Mr. DURANT. I do not believe I would object, in principle, to the way this is written at this time. If I might interject one thing here, I think it has been clearly brought out that the all-important person is the Director and if he is a wise man, a knowledgeable man, he will draw from wherever he can find strength and technical competence in this country.

Mr. NATCHER. I would like to have you describe to the committee the type of man that the Director should be. What should be his qualifications? If you selected him, what type of individual would you select?

I have this in mind, and I would like you to start with this premise. Should he first be a scientist? Should he be a man with a lot of administrative ability, with proven qualities? What type should he be? How do you feel about it?

Dr. BERKNER. In my opinion, Mr. Natcher, he must be a scientist because the major decisions he must make involve the evaluation of the recommendations of subordinates concerning matter of scientific research and engineering.

In addition, he must also be an administrator. After all, we have in the United States at the present time a very substantial number of men with excellent scientific training, many of whom have made original contributions, who also are proven administrators. I am sure that such men will be found.

Mr. NATCHER. Now, I would like to hear from you, Mr. Durant.

Mr. DURANT. The only other point I would make, before I comment upon the type of person required as Director, is my opinion that in whatever way the bill is written, the Director, if he is the right man, will draw from the strength of this country with respect to those rocket research and development teams which have a sound record of achievement. There are also many individuals who have distinguished themselves over the past 5 or 10 years, who have worked very hard in studies, mostly on their own time, and at considerable personal effort and risk to their own reputation. These individuals have worked hard and contributed greatly to the science and technologies of space flight. These teams and individuals, somehow, must be used in any national space flight program.

I presume that when any United States space agency evolves that rather than building up a tremendous colossus, which within itself would perform all space flight research, development, and production, that much of the work would be contracted to individual teams no matter where they are, whether they are in industry or are in various arms of the services.

For instance, we have a powerful team at Huntsville, Ala., we have another one at the Naval Research Laboratory, and others in the aircraft and missile industries. I hope sincerely that these people will have the opportunity to contribute in this work.

Now in regard to the director of a national Space Agency, it seems to me that we need a strong voice at the top, a civilian—without doubt a scientist—and one who has a distinguished record not only in administration but also in knowledgeability of the subject he is about to direct. You cannot learn the business of space flight overnight. One of the major reasons why many of the former German nationals are so competent is the 10 to 15 years head start on our scientists and engineers in thinking on and working on rocket developments.

The CHAIRMAN. Above all, he has to have the respect of the scientific community.

Mr. DURANT. The respect of the scientific community and also, I believe, the technical people, the engineering community which will be involved.

The CHAIRMAN. I meant to include them. He does not necessarily have to be a scientist, but the fact that he is a scientist should not bar him?

Mr. DURANT. No. I think, undoubtedly, he would be a scientist, one who has had a significant amount of academic training.

The CHAIRMAN. Is Dr. Killian a scientist?

Mr. DURANT. I think he is a scientist.

The CHAIRMAN. He testified he is not.

Mr. DURANT. I think it is a matter of education and training. One can substitute years of responsible work and achievement for some academic training.

The CHAIRMAN. Is it not hard to locate in this field the administrators that have the respect of all elements that make up the activities, particularly in the scientific field?

Mr. DURANT. I would like to suggest, for example, that Dr. Wernher von Braun is not generally considered a scientist, yet he has a doctor's degree and has outstanding proven experience. In the final analysis you come down to the man himself. It is imperative that the qualities of leadership, enthusiasm, and humility backed by sound experience and a successful professional record.

The position of space agency director will carry a tremendous responsibility. Whoever is chosen, the results of his endeavors, in the next few years will affect the future strength of this country in a most vital way.

The CHAIRMAN. If the director form of agency is decided upon, the sum and substance of the testimony of both of you is that the President should be very, very careful in his selection?

Mr. DURANT. Indeed, sir.

The CHAIRMAN. Do you agree to that, Admiral?

Dr. BERKNER. Yes.

Mr. NATCHER. Gentlemen, what suggestions do either of you have that will be of benefit to the committee in strengthening this bill and putting it in better shape? Do either of you have suggestions?

Dr. BERKNER. I would say, Mr. Natcher, that in my opinion the bill is in fairly good shape at the present time. Now, I have had no legal training and there may be many of you who can turn a legal

mind to the bill and can see language that must be clarified to make its intent unambiguous.

The CHAIRMAN. For example, the bill states: "The Congress further declares that such activities should be directed by a civilian agency * * *." "Should" is a kind of cloudy word. Should it not be "shall be"?

Then there is the question of the liaison committee between this agency and the Defense Department and the AEC which is not provided for. There is a question of what position will the Congress take in connection with a committee, joint or otherwise. There is nothing on patents in here protecting the Government.

Of course, we do not expect you gentlemen to have knowledge of all those aspects. Of course, some individual largely drafted this bill. We know who drafted it and he did a pretty good job, sufficiently so that I introduced it.

Ordinarily, if I did not agree with the bill, as chairman of the committee I would put the words "upon request" on it, but I did not do so. I think the bill provides a very good basis for the committee's consideration.

So there are many improvements here that can be made although the bill is a good basis to act upon.

Dr. BERKNER. I must say with respect to your comment on the joint committee that I have always had a great admiration for the effectiveness of the Joint Committee on Atomic Energy of the Congress, and particularly the searching studies of my old friend, Senator Anderson.

The CHAIRMAN. He is a House-trained member, you know.

Dr. BERKNER. So I recall. Certainly, this committee has demonstrated one thing for atomic energy in the legislative branch because of its joint character that would be very valuable if carried over into the space work; that is, because of its joint character, the committee has been able to devote a great deal of time and effort to the single hearings. It has covered very much ground of a kind which I think the Congress has a right and duty to cover. The same kind of thorough studies should be covered with respect to the Space Agency by Congress.

I think it would be certainly worth your careful consideration to think in terms of a joint congressional committee for this important future activity.

The CHAIRMAN. I refer to these because we have them in mind, but there may be some suggestions from the scientific angle that you gentlemen might make.

For example, you might consider the declaration of policy, whether it is broad enough, whether it states the intent of Congress. That has great importance. I would level on that.

And from the scientific field I, as one member, would like to get some opinion, not confining it to the declaration of policy, but I would suggest that interested parties in the scientific field level on that declaration of policy and transmit their suggestions to us.

Mr. DURANT. The declaration of policy is really very well written. I would turn to item 6 of the declaration of policy. I would assume that this permits the cooperation of this agency with the scientists of other nations as well as those of the United States.

The CHAIRMAN. You may be right, cooperation of the other nations or groups of nations. That means on the level of nations, not

individuals. Both of you have stressed that. That is just one illustration where I think the intent is to improve that.

But suppose that language is in the bill and it becomes law and you are the director or administrator—I think director is too limited a term for this important activity. The thought enters my mind, I noticed that before, would that allow them to engage in the exchange of information, talks, and so forth with individuals or groups within nations? That is something to think about.

Mr. DURANT. Mr. McCormack, I think you very clearly pointed out something that I did have checked here also. I feel this might be amended to say "or organizations within these nations as appropriate." But I think, coming back to the bill itself and with respect to the policy as stated, it is well written and I think there will be opportunity for amendments and clarifications later on.

But with the proper director and with the spirit of the bill—the spirit is excellent—I believe that these matters will sort themselves out. I think you are quite right with respect to discussions only at the national level, we will not accomplish what Dr. Berkner and I hope will result from the future cooperation of scientists and groups of scientists on an international basis.

The CHAIRMAN. I asked the question only in connection with my original suggestion that you gentlemen and others in the scientific community make suggestions to the committee. I hope it will be soon, because we are going into executive session in the not remote future.

This committee as you know has taken the lead. We have been devoting our time 5 days a week, which is unusual, morning and afternoon, and all these members are all members of other important committees and I happen to be a majority leader, yet I am very proud of this committee, their devotion to their duty, their mission, their task.

We have been devoting our time and it is important to get any suggestions within the reasonably near future because we are going into executive session for the purpose of writing a bill some time after May 7.

Dr. BERKNER. Mr. Chairman, in the declaration I would take a look at one more point, point No. 7, which says:

> The most effective utilization of the scientific and engineering resources of the United States and the avoidance of duplication of facilities and equipment.

One must read these words very carefully to determine whether this means the Agency feels itself obliged, under the definition of policy, to accept the participation of scientists in the universities and institutions where many of the greatest skills for space research will be found.

You will note in my testimony on page 3, I emphasized the point that this language should permit any qualified scientists to plan and prepare a useful space experiment at his university or in his laboratory with the expectation of getting it into space with the cooperation of space agencies, of course within the restrictions of the funds and technology available.

I think this is very important because one would hate to see a Government monopoly set up in this Agency; I would assume that the legislation should be quite clear on this point.

The CHAIRMAN. In other words, you think we should say something about the power to make contracts?

Dr. BERKNER. Certainly to encourage the Agency to cooperate with American science generally in the achievement of its objectives.

The CHAIRMAN. I think that is the intent.

Mr. DURANT. Mr. McCormack, turning to line 23, page 2, item 6, "Cooperation by the United States with other," and then if it was "appropriate organizations and individuals of all nations and groups of nations," some wording of this sort would indicate that it would be possible and desirable.

The CHAIRMAN. That could be worked out. Level on it and give us your suggestions.

Mr. DURANT. Again on item 7 where it talks about the avoidance of duplication, I think it is the standard military phraseology in bills to say "avoidance of unnecessary duplication," because again it is sometimes desirable and prudent to have parallel programs in important developmental work.

The CHAIRMAN. I would think this is more in respect to governmental technical avoidance of duplication of facilities and equipment. That is a very desirable objective.

Mr. DURANT. Yes, sir, but it does not necessarily mean any necessary duplication would be improper.

The CHAIRMAN. Again you have to apply the rule of reason.

Mr. DURANT. Correct. This, then, comes back to the director.

The CHAIRMAN. And it comes back to the matter of administration. You cannot write every little thing. If you wrote every detail, you would put a man in a straitjacket. You have to have some confidence in those who administer it. I have, until it is proven to the contrary.

Mr. Natcher.

Mr. NATCHER. Mr. Durant, I would like to direct this question to you. The Soviet Union has a crash program underway at the present time in the missile and satellite field. How do you feel about a crash program in this country after enactment of this legislation?

Mr. DURANT. Mr. Natcher, that is a loaded question. I think the problem is one really of defining what you mean by "crash program."

Mr. NATCHER. Let us put it on this basis, Mr. Durant: Should our program be speeded up considerably from the program that is now underway? Let us start there.

Mr. DURANT. I would certainly answer that question in the affirmative. In fact, I might comment that our efforts have been rather slowed down on a national basis during the past 6 months while awaiting action upon such a bill such as you are considering and authority and funds to go ahead with space-flight research.

The military, particularly the Air Research and Development Command, and the Army Ballistic Missile Agency and the Naval Research Laboratory, all have advanced projects which are awaiting approval. Likewise, industry has worked up proposals for substantial space-flight programs.

Now, it is going to take a while for this proposed organization to get underway and I certainly presume that the Advanced Research Projects Agency (ARPA) will continue in being and given authority and funds to go ahead for the time being.

However, I do not like the term "crash program" because unless you know exactly where you are going to go, as we did in the atomic energy work during the war, which was a crash program, I do not believe that such a program is desirable until it is known clearly who

is going to administer the program. It should then be funded on a long-range basis. At that time full speed could, and should, be applied.

I believe that space research is of tremendous importance to the future of this country. To that end I believe that due recognition of this should be given by the highest levels in the country, with communication to the President, and certainly with the National Security Council. I am convinced that such action will be approved by the citizens of this country.

Mr. NATCHER. Thank you very much.

The CHAIRMAN. Mr. Fulton.

Mr. FULTON. I am glad to have you gentlemen here and I think you have contributed a great deal to the development of this science and to this committee.

My question first comes up, how should we in the United States approach space? Shall we do it in the context of a race with Russia, or shall we do it on our own under a national policy that is instrumented by a national space agency?

I happen to be the Republican side at this point, but I make up in interest what I lack in numbers.

Dr. BERKNER. In my opinion, Mr. Fulton, we cannot ignore the effort that Russia is making in this field in the establishment of any program.

Mr. DURANT. I concur with Dr. Berkner.

Mr. FULTON. So in relation to Mr. Natcher's question, you would speed up our programs, broaden them on many fronts, and continue basic research and study, as well as an implementation program?

Dr. BERKNER. I would say it like this:

I think if we were to try to match their achievements one by one, we probably always would lag.

It seems to me we must set up a program looking to a reasonable distance in the future, perhaps 5 years, programing our effort so that we will have a reasonable expectation of staying parallel with them in most fields and ahead of them in some.

Mr. FULTON. So that we choose our own course rather than always try to match and be a close second.

Dr. BERKNER. Yes, sir.

Mr. FULTON. Would you comment, Mr. Durant?

Mr. DURANT. Mr. Fulton, I think that whenever this bill, in some form, is authorized or someone is given the authority to go ahead and plan and program space research, the first action should be to stop for a month or 2, and for the key individuals to study and decide upon; first, a short-range program, which would be on the order of 2 to 5 years, and secondly, a longer range program, 5 to 10 years.

I believe that the Agency's programs inherently should be drafted with confidence, show initiative, and a certain boldness.

As Dr. Kantrowitz has suggested, "a spirit of adventure" should be built into the planning and administration of the United States program.

Such an approach does not necessarily mean extraordinary cost. On the contrary, a bold program will result in more rapid advancement and greater scientific benefits in the long run.

I think that the suggestion of the "plateaus of capability" made by Mr. Ehricke are really significant. These plateaus of capability in-

clude within each "plateau" the ability to carry out many research projects. The decision to conduct a particular project may be decided upon at a later date in the light of subsequent events.

We certainly do not want to, in fact could not afford to, perform all of these various projects that have been suggested to date. There have been some very, very poor suggestions put forward publicly to date, in addition to some very fine programs.

If we attempt to match the Soviets or if we attempt merely to do spectacular things without a clear appreciation of the scientific and technical potential, then we are going to lag in the race. And it is a race; we will be, in the vernacular, in the Russian rocket exhaust for the indefinite future if we do attempt simply to match their accomplishments.

The U. S. S. R. commission on astronautics has a program, they have authority and funds, they are in motion.

In the case of the United States, we are still trying to get into motion.

Mr. FULTON. Your comments as a scientist have interested me because the question then comes up, what happened in science in Russia historically?

For example, in 1927 it was Tupelov who said that the Lenin method of scientific concentration and centralized control should be dispensed with.

So in 1927 the Russians changed their system and got decentralized science. Likewise, they moved it from one person into a vice minister who is on the Council of Ministers and then put the Academy of Sciences separately under a science secretary who is really not political, but largely scientific. Is that not right?

Mr. DURANT. From my understanding of the organization of the U. S. S. R. Academy of Sciences, you are correct.

Mr. FULTON. The question comes up when you in your statements have been complimenting the Russians on their fast progress. As a matter of fact, in the statement of Mr. Durant, he says in the second paragraph regarding the Commission on Astronautics, Academy of Sciences, U. S. S. R.:

> This body had the responsibility to organize the program, to assign the appropriate research tasks and to see that this work was carried out. Their job was to identify the basic problems which had to be answered before scientific research could be launched, and obtain the answers. They were eminently successful.

Now, remarkably that is a specific recommendation for a commission type of approach to the astronautics and aeronautics field because it has worked for the Russians.

Actually, it has done better, in some minds, than the United States has been able to do.

Now, my question is this: If the tried and proven methods that have been used have resulted in an eminently successful result in Russia in this very field and likewise when the tried and true commission form has been used on the Atomic Energy Commission, why should not this committee in recommending policy to the Congress and the country recommend a commission form of five members?

My point is this: Instead of having one man who is in charge, as General Groves was in the Manhattan project, which we quickly left in the United States and then moved over to a civilian agency,

why do we not in the aeronautics field start originally with a civilian agency that has the primary responsibility of making a national space policy for the United States overall? Why do we not just start with that?

Dr. BERKNER. Mr. Fulton, was it not true that the Soviet Union used a single overall director for its planning for the satellite project? That was General Blagonavov, starting in 1950.

Mr. FULTON. May I comment on that?

On the matter of implementation I would assume, when it comes to specific programs, they should have personal direction.

For example, on this Commission I would probably put as the Chairman of it Dr. DuBridge, the president of the University of Cal Tech. I would put on a man in charge of nuclear and atomic research, and to conform it to space use, a man like Admiral Rickover.

I would put on, maybe a person who is interested in the far reaches of development, a man like Admiral Hayward, head of research and development in the Navy.

Likewise, because the good Dr. Dryden has been head of the NACA and has done an excellent job in aeronautics, I might put him on the job as an aeronautics member.

Mr. DURANT. Mr. Fulton, might I suggest that you might also have as a representative in such a commission a space medical man?

Mr. FULTON. My other recommendation would be a person who has a military background, but who is a civilian, and that would be Dr. York, head of ARPA, the agency for advanced research programs.

If we did that we would be doing something like Russia has done because on the Committee on Astronautics right now there is, first, a man who is a straight military man, an ordnance representative and secondly, a man who is one of their academy men, more of a professional type, but interested in the military. Is that not right?

Dr. BERKNER. Mr. Fulton, I would be very much afraid of this organization. I am sure it would have great brains, but it could not possibly have the singular purpose of the kind that was deliberately used by the Soviet Union in directing their present program.

We must remember that our program lagged, not because we had a single director (which we didn't) but because we were slow in organizing our rocket research. Starting way back in the 1950's and running right down to 1955, when we were told to go ahead with the satellite program, there had been two serious breaks in our rocket program.

Mr. FULTON. Were you scientists not at fault, because my interest began in 1945 and I have been interested ever since? Were you not at fault in not trying to stir up public opinion in this country to back you on a broader basis, and, secondly, were you not at fault in not telling us that the Russians were aiming at a faster program than we were and were going to outstrip us?

Dr. BERKNER. I suppose we tried to do this. I think we might find statements to the point. Because we did not have the kind of agency we are discussing now, there was no one to defend the two great cuts that took place. I think these are equally distributed, one under the Republican and one under the Democratic Congress in the Naval Research Laboratory program, which is the direct antecedent to the present Vanguard program.

Mr. FULTON. I might add that I voted against all cuts, straight through, in the military research program.

Dr. BERKNER. My point is the following: That our delay in getting the Vanguards up, I think, if it can be traced to anything, was the general slowness of getting started on our rocket program generally.

Mr. FULTON. Were we not trying to instrument too much when the Russians were just going to shoot a cannonball out of a cannon? We were trying to put on an instrument for solar energy and to go ahead with it as a project under the International Geophysical Year, while the Russians suddenly decided they would get ahead of us.

Dr. BERKNER. It is my view, if you will read this announcement of their scientific accomplishments, that they were pretty well instrumented. I think we would have looked very foolish, indeed, just to shoot a ball out of a cannon without trying to do the scientific job. I think that the intellectual people in the world are a bit too sharp to be taken in by the mere propaganda of having a shot landing on the moon with a great big splash, but with no scientific meaning.

Mr. FULTON. There was opinion in the United States that we were doing a lot of research. We in August 1957 had the Russians come here and visit our facilities and talk with our scientists on the earth-satellite program. Then there is a feeling in many quarters that it was like the canary that jumps on the eagle's back. When the eagle flies high as it can and then just as it reaches the top the canary jumps 30 feet higher and it has the record.

Dr. BERKNER. Certainly at that time we did not anticipate the dates of launchings of the Soviet satellite.

The thing that held up our program was not the scientific work that was done on our satellites, but it was the rockets. Now, just yesterday there was another failure of the rockets. Every satellite that we have been able to put in orbit has worked successfully from the very beginning in the scientific sense.

So the difficulties that we had did not stem from the work that we have done on the scientific side of the satellite program. Certainly every bit of this work was justified.

But our failures have come from our failures in making good rockets.

Mr. DURANT. I merely want to concur very strongly with Dr. Berkner. First, for the record, if I might comment on the Commission on Astronautics of the U. S. S. R. and the suggestion that we might follow a similar commission in this country.

Mr. FULTON. No, not a similar commission; our own type, such as the Atomic Energy Commission.

Mr. DURANT. I think we should examine that from the point of view of how well it worked with AEC, not with respect to how well it worked in the U. S. S. R.——

Mr. FULTON. I think we should be openminded and look at both. Here we have two tremendous advances made by the commission type, one the AEC in this country, the other the commission in Russia, under the Academy of Sciences.

Mr. DURANT. One reason they did accomplish so much, of course, is that they got off to an earlier start.

Mr. FULTON. What is wrong with the commission form in this country? What do you see as the defect?

Mr. DURANT. I believe that either would work. It is a matter of the spirit with which it is gone about.

Mr. FULTON. May I ask Dr. Berkner that?

Dr. BERKNER. I will point out that the great advances in this country, which first started with atomic energy, took place under a single direction. We must remember that the major advances, the proving out of atomic energy both in reactors and in nuclear weapons took place when General Groves was the czar, if you like, of the program.

Likewise, I would point out only this week in the journal Science that Mr. Ginsberg made the remark that under the direction of Dr. DuBridge, who was the single director of the radiation laboratory at MIT during the war, 50 years work was done on radar in 5 years. That is the kind of progress we need in space research and exploration.

Mr. FULTON. That is why I have recommended Dr. DuBridge as the chairman because he not only has had previous experience and has compressed tremendous research into a short time, but he has organizing and administrative ability and has administered the university pretty well. Besides, he can raise money.

Mr. DURANT. Mr. Fulton, I think you mentioned something about the extremely complex instrumentation of our Vanguard program. As Dr. Berkner pointed out, this did not affect in any way our launching dates. The launching dates of the Vanguard program itself, its troubles, have been completely concerned solely with launching vehicle reliability. Since I had some connection originally with the Orbiter program, I feel strongly about this.

Mr. FULTON. The members of the Astronautics Federation are all free countries, except the U. S. S. R., Poland, and Yugoslavia?

Mr. DURANT. Those are the Communist countries represented by member societies of the IAF.

Mr. FULTON. In the International Astronautical Federation, did they deal with other coutries as units, as if they were delegations, by country, or did they divide off by scientists and disagree among each other, even though they were from the same nation?

Mr. DURANT. As individuals, sir.

Mr. FULTON. Do you agree on that?

Dr. BERKNER. Yes; very much so.

Mr. FULTON. Let us ask about the International Geophysical Year, as to how it was handled there. It is not clear from the statements whether these scientists were disagreeing among themselves or were acting as country teams. On your meetings with them at the various conferences and in this country, did they deal, for example, as Soviet teams, or did they disagree among themselves?

Dr. BERKNER. Both. If purely scientific matters were under discussion, one always dealt person to person, one scientist to another.

However, in the International Geophysical Year there was involved the commitment on the part of each nation for the expenditures of large sums of money for certain planned national programs which must dovetail together. When one deals with the expenditures of money and the commitment of nations to such expenditures which, after all, comes back on our side to the Congress and their side to the Soviet Ministry, then their delegations dealt as national delegations.

Mr. FULTON. The question comes up: How shall we fit this into our structure of government? Where does space begin and sovereignty end? We in this country have the sovereignty of the Fed-

eral Government and we likewise have the individual sovereignty of the 48 States.

I am from Pennsylvania. Each State owns above it to infinity. How will we work the national space policy so that we do not get involved, first in a question of Federal sovereignty and, secondly, in 48 State-sovereignty questions? Where do those sovereignties end to you?

Dr. BERKNER. This, of course, is a question that might best be answered by someone who is legally trained. My own view has always been that winged vehicles travel from point to point on the surface of the earth, travel in a space which is certainly controllable by the nations of origin and the nations of destination and, perhaps, the nations of overflight. But when one goes beyond this limit, we certainly already have established the precedent, to which no nation has objected, that satellites for scientific research can fly overhead.

Mr. FULTON. A plane goes 100 miles in the air that would possibly be a security matter to us and something that we would want either to control the method of the type of instrument or the destination, if it was over the United States, would we not?

Dr. BERKNER. This certainly includes, of course, our ability to police any regulations that are established.

Mr. FULTON. That brings into question what our basic view should be. Are we looking at space, as has been mentioned here many times, in the light of the freedom of the seas, as Grotius spoke about it, or are we looking at space the way England looked at it when John Seldon said in 1665 that England must obtain dominion of the seas to maintain its freedom? They had the power to control the seas, and they used it for a good many years.

Or should we start through the United Nations and try to draw up some law on use of outer space. Or, should we go beyond the United Nations? Should we steer away from the politics of the Security Council and the limitations of the General Assembly, where all nations do not assemble, and do as they did in 1899? You will recall that in 1899 the United States joined in the first Hague Conference, and that included every interested nation.

The question then would be: Should we again take the lead, as we did in 1899, or should we let Russia take the lead, as she did in the second Hague Conference when, in 1907, the United States accepted Russia's invitation to a conference at The Hague to talk about the World Court and international questions?

You see, we have once taken the lead and Russia has taken the lead once, on an international conference on a broader basis than just the United Nations. Now, I have favored the latter one. What do you favor? I think it should be first taken up in NATO in a preparatory meeting and then it should be dealt with by the President on a wide area, similar to the Hague Conference.

Dr. BERKNER. You have gone to the very heart of the basic legal problem that underlies the whole space situation. Certainly, something must be done about this very soon, because we all can see problems coming up very rapidly. Let us be specific about these problems. First of all, the very fact that we are launching a series of satellites, each one with a radio transmitter, in itself, will produce a certain amount of radio interference. This interference may deny the use of

the same channels for other purposes. For example, it is likely that the Vangard rocket, with its solar batteries and its small transmitter, will be heard on the frequency of 108 megacycles by your grandchildren. It is said it will stay up from 100 to 200 years.

Now, if large numbers of satellites are launched in a totally unregulated fashion, both by the United States and by Russia and, perhaps, by other nations without thinking ahead of the problems that will be created just because of this interference, we could deny ourselves a substantial communication potentiality.

Mr. FULTON. The same goes for States. Suppose the Commonwealth of Pennsylvania said it was going to put a satellite into orbit, and then each one of the 48 States felt it had to go along, and each college says, "We cannot let the other college get ahead of us, so we will put our own up." Then you get the other fellows down on Y Street who have a rocket club and they decide to put a satellite into space. Wouldn't we have a congestion, a traffic problem and, actually, an outer-space garbage dump?

Dr. BERKNER. I would doubt very much if the States would launch independently because of the interstate interests that should be properly controlled by the Federal Government.

Mr. FULTON. Should we make it exclusive, so that you would require a permit, license, or passport either to go into outer space or to project anything beyond what we would call the ordinary aeronautics channels?

Dr. BERKNER. This is absolutely imperative, but it should be done through international agreement, using some mechanism very much like the one we use in the allocation of radio frequencies.

Mr. FULTON. So, you would not let private citizens do something in outer space without Federal Government approval?

Dr. BERKNER. Or even a nation, without the approval of an agreed-upon international body.

Mr. FULTON. When you come to the international approach, when we set up a space agency, we would have to have a foreign section of the Space Agency just the way the Soviets have a foreign section of their Academy of Sciences, would we not?

Dr. BERKNER. Perhaps, working with a section in the Department of State similar to that which we now maintain to carry on our international negotiations in the field of communications.

Mr. FULTON. The trouble with the Department of State on its sciences attachés is that they are under the Department of State, while the Department of Agriculture has been wise enough to make its agriculture attachés directly responsible to the Department of Agriculture. Would you have these science attachés moved over and be made responsible to a new space agency?

Dr. BERKNER. No, sir; the Department of State must be in a position of negotiating treaties and agreements. I believe this is something that should not be delegated to other agencies of the United States Government.

Mr. FULTON. But the International Geophysical Year was set up, operated, carried out, and is being carried further with no international agreement at all by the United States Government?

Dr. BERKNER. By all governments concerned through a nongovernmental agency; yes.

Mr. FULTON. But it has only been by nongovernmental agencies and not by a treaty, nor by an executive agreement. Is that not correct?

Dr. BERKNER. That is correct.

Mr. FULTON. Then it has been done already.

Dr. BERKNER. Yes; but when it comes to launching large numbers of satellites we are asking for real difficulty if we do not have an international agreement on the control of launchings. Let us look at a specific example. It seems quite clear in the very near future that we shall launch a small number of satellites, perhaps 3 or 4, to an appropriate altitude. These will be either of size sufficient for reflection of radio waves, or with power enough to permit the relay of radio waves, to provide for the equivalent of the whole ionosphere for a new worldwide communications system.

Now, the value of those satellites aloft for communication purposes will be somewhere between $1 billion and $10 billion. This is an objective worth looking at.

The point is that Russia can do the same. Any other nation can do the same and there are strong financial motivations for them to do so. Quite clearly these could interfere with one another, each one negating what the other is doing.

Consequently, it will be desirable for intricate negotiations to be carried out whereby these can be erected and used internationally. Then, far from interfering with one another, they provide each nation with certain measures of communications capability.

Mr. FULTON. You are really rebutting what you have said at the bottom of page 3, last paragraph, about freedom of enterprise in outer space. You say this—I agree with you now but I disagree on the statement that—

I interpret this language as meaning that any qualified scientist can plan and prepare a useful space experiment at his university—

Who would decide what is useful? "At his university" or in his laboratory with the expectation of getting it into space with the cooperation of the Space Agency within the restrictions of the funds and technology available.

This means that the best of American science, wherever it is found, can have access to space through the means and cooperation that its Government provides. This provision insures the healthy growth of space science and avoids a governmental monopoly on one of the important scientific activities of the future.

You see, if it is going to be completely free for the boys in Pittsburgh to put their satellites up as long as they have the cooperation and the use of certain facilities, that is one thing. But if we are going to put in this bill that it shall be a Federal jurisdiction exclusively and deny them access to space, it will have to be on an agency that has a licensing power so that we will, in the Federal Government, issue either licenses or passports for operations or for moving into outer space.

Dr. BERKNER. In my statement, Mr. Fulton, I had assumed that no one except the Space Agency and the Department of Defense would have the privilege of erecting a payload. I had interpreted the legislation as restricting the erection of payload into space by other than the military and the Space Agency.

When I made this statement in my testimony I interpreted the legislation to mean that the payloads would be provided by the Space Agency on which these experiments could be mounted.

Mr. FULTON. Could you make a further statement in the record? We are going to have to go at 12 o'clock. Would you put a statement in the record on that?

Dr. BERKNER. Yes, sir.

Mr. FULTON. I want you to amplify on page 4 that the Space Agency shall have full authority to initiate its own space research directly. That means that we will have the next Columbus go out under the guidance, direction, and authority of the National Space Agency and that is a required authority to be effective.

Secondly, I would like you to have an amplification of the necessity of a new agency to supplement the agencies already there so that we will not be uselessly spending taxpayers' money.

Next, I would like the viewpoint of each of you on the programs that are practical at the present time and that should be pushed promptly. Likewise, the basic research programs that we should be engaged in with study continued for the next 3 to 5 years.

Would you also, please, put in the record the books and pamphlets that you feel are necessary for this committee to study and, secondly, what you would recommend for the layman reader in the astronautic and space field so that we have a good bibliography?

Dr. BERKNER. Yes.

Launching of satellites and space exploration will be a difficult and expensive procedure for as long in the future as we can foresee. In return, such activities will be very remunerative and productive in their results to American science and industry.

Space activities will fall into three general categories:

(a) Scientific research and space exploration;
(b) Commercial activities such as communications systems;
(c) Military activities such as reconnaissance and intelligence.

It seems evident at this time that some forms of international regulation and control of space launching should be adopted to avoid a number of serious problems that are certain to arise. Such problems include:

1. Optimum use of satellites for research to reduce the numbers of satellites in flight to the number necessary. This should be done to avoid unnecessary radio interference between them, and between satellites and the ground;

2. Maintenance of international orbital scheduling to avoid alerts of early warning systems;

3. Effective utilization of satellites for world communications systems;

4. Avoidance of improper use of satellites that may produce deliberate radio interference or other undesirable consequences that might lead to punitive action;

5. Encouragement of international cooperative activity and space research and exploration.

Such regulation and control should be in addition to present activities of the International Council of Scientific Unions in planning specific international space activities and experimental programs.

In view of the cost, the regulatory problem, and the potential international problems introduced by space operations, I believe that

all launchings into space by the United States must necessarily be carried out directly under governmental control and sponsorship. Under this bill, such launchings could be made either under the Department of Defense or the NASA. But I do not visualize anyone else with the money or authority to launch payloads for space science, to direct space stations, or to carry on space explorations.

However, to enjoy the full cooperation of American science, the NASA should cooperate closely with the National Academy of Sciences and individual scientific groups in determining which experiments should be done and in what order of priority. Moreover, qualified scientists should be given the opportunity to carry out their experiments in payloads offered by the NASA so that American science generally has access to space. My original statement was directed to this point.

The NASA is essential to full exploitation of the potentialities of space science. The military applications are necessarily specialized and limited, and the military agencies do not have as their first objectives, the full development of space activities. Moreover, the military agencies should not be overloaded with activities not directly related to national defense. They already have more than enough responsibility to do their job well and efficiently.

In my opinion, the present bill assigns the whole nonmilitary responsibility to the NASA under conditions that will lead to the most efficient, economical, and productive exploitation of space science and the industry emergent from it.

To assess the most useful and effective programs, the NASA might best ask the appraisal of the present situation by the National Academy of Sciences. The NAS by law has the broad responsibility to recommend to the Government at its request, those scientific and technical measures deemed in the best interests of the country. It has access to all American science and engineering. From an appraisal by the NAS, a sound and effective space program should emerge. Such an appraisal should be made immediately and followed by continuing reviews and reappraisals. Guidance of this kind can be of the greatest aid to the NASA.

Mr. Durant. In my opinion the next space flight research project of real significance is not more or larger or more highly instrumented satellite vehicles. Nor is it the lunar impacting and telemetering rocket, nor the circumlunar rocket, nor even the planetary "probes." All of these projects are mere extrapolations of today's satellite achievements.

The next really significant step in the development of astronautics is the manned satellite. This first step of man, himself, into space in a satellite vehicle followed by his safe return to earth will be an achievement of many orders of magnitude greater than any instrumented space flight vehicles even if they carry television cameras.

There is much talk of what man will eventually do in space, on the moon, and so on. However, all manned space flight is contingent upon the achievement of two important developments not yet undertaken, namely:

1. The determination of man's physical capabilities in space, under conditions of prolonged weightlessness.

2. The proof of the technical feasibility of a satellite recovery system which will return man to earth safely to a specified area on its surface.

No plans for manned space flight can go forward without these achievements. This is why I say that a manned satellite flight looms clearly as the next truly significant space flight project. As to a bibliography on astronautics, it seems to me that the one listed on pages 168–174 of the March 1958 issue of magazine Air Force, published by the Air Force Association, is splendid. The February 1958 issue of Sky and Telescope contains an excellent survey of national and foreign periodical literature of astronautics by Frederick I. Ordway III.

There is now a wealth of space literature—perhaps too great—for the newcomer. There are specialized bibliographies, too, for those with particular interests; such as, space medicine, astronomy, propulsion (liquid and solid propellent), philosophy, law, amateur experimentation.

Mr. McDonough. Mr. Durant, I appreciate your contribution this morning. You have given us a great deal of information. As I remember, your statement concerning the possibility of an independent agency for developing basic science for practical application to space technology would be under the jurisdiction of the Space Agency that we are establishing here, as I understand it.

Mr. Durant. Yes; I did not propose another agency of any sort. What I meant in my statement was to delineate certain programs that I believe should be incorporated into our national program.

Mr. McDonough. In other words, I understand you to say that anyone, private citizen, university, or individual equipped with such knowledge that develops any basic information that will be valuable, before it can be implemented and actually shot into space or put into practice, it should be referred and cleared through this Space Committee?

Mr. Durant. Yes, as appropriate.

Mr. McDonough. And the kids in the backyard up in Pittsburgh are not going to shoot rockets into space without the approval of this Agency?

Mr. Durant. Well, I am quite certain there will be no satellites launched by any young people's rocket club although I have, and my record shows I have, given a great deal of time to the encouragement of youth in the study of the subject.

Mr. McDonough. Yes; which I agree with and I think we should have encouragement at the high-school level in the science class to understand the geometry and physical sciences necessary to promote space technology.

Now, in reference to your review of the organization in Russia, you have provided us with a lot of valuable information about the names of those who are members of the interdepartmental commission on interplanetary travel of the Aeronautics Council of the Academy of Science of the U. S. S. R. Do we not have, or do you know whether we have, the counterpart of such scientists in the United States, if we need to coordinate and marshall our scientific resources under such an agency?

Mr. Durant. I am convinced we have not only counterparts but in some cases better scientists. On the whole, I'd say we have the equivalent scientists.

Mr. McDONOUGH. I am glad to hear that. Now with all the implementation of basic scientific law that Russia has been doing since the establishment of their organization since 1955, up to the present time they have shot two satellites into space. They have shot a ballistic missile the full range, so-called; at least we hear they have.

We have shot three satellites into space. We have had a few failures. We have made several advances. We have shot a ballistic missile the full range. For the length of time that we have been at it, as compared to the length of time Russia has been at it, how much further ahead of us are they?

Mr. DURANT. The United States has been engaged in the development of long-range ballistic missiles a shorter time than the Russians. Large size rocket vehicles are the sine qua non of any satellite launching program. The Russians completed the development of reliable big thrust engines earlier than we did because they started earlier.

The Russians put satellites into space because they started earlier and they are ahead of us now because they set up a program earlier, not because of any great technical superiority.

Mr. McDONOUGH. That does not mean that we cannot catch up.

Mr. DURANT. It does not mean that we cannot catch up. I think it is vital that in our planning to catch up that we do not simply duplicate what they are doing.

Mr. McDONOUGH. In other words, even if their scientific organizations do provide, and they of course are studying these matters under the same basic physical laws that we are, there is not any change. They cannot repeal the law of gravity, the cannot magnify it, they cannot change the distances between the planets nor can they change the distances in outer space. So we are following along the same road with any new application of space technology.

Are they better equipped, in your opinion, or do you know whether their industrial capabilities are any better than ours if we had the same information and were attempting to make the same kind of hardware.

Mr. DURANT. I would say our industrial capabilities are greater at this time. These capabilities have not been directed toward space flight. With the type of government that exists in the U. S. S. R. it is possible to bring tremendous effort to bear on specified projects.

I believe the Russian achievements of the fission bomb, nuclear fusion bomb, the MIG–15, and satellites are clear evidence that they can perform important technological feats. To match and exceed such ability, as I have suggested, positive action, creative thinking, a well organized program and powerful leadership are necessary.

We can certainly catch up and we can pass them, but we must organize and plan for it and utilize the best talent willing and interested in such work.

Mr. McDONOUGH. Thank you very much.

Mr. BROOKS (presiding). Mr. Keating.

Mr. KEATING. No questions.

Mr. BROOKS. Mr. Feldman.

Mr. FELDMAN. Dr. Berkner, in response to a previous question you mentioned the fact that it might be desirable to have a joint congressional committee similar to the Joint Committee on Atomic Energy, is that not so?

Dr. BERKNER. Yes, sir.

Mr. FELDMAN. Would that not more nearly function like a board of directors or trustees because they would, in effect, oversee the activities of a commission, an administrator, or director, as the case may be?

Dr. BERKNER. It has been my observation that the Joint Atomic Energy Committee on the whole has looked carefully at all the functions that Congress should properly perform and has had the opportunity under the circumstances to inform itself very fully and very effectively so that the AEC has had the strong support of the Congress.

Mr. FELDMAN. And has assisted it not only on congressional matters but on matters of the budget?

Dr. BERKNER. Certainly. Above all, there have been produced by the Joint Atomic Energy Committee a number of volumes of information which are extremely valuable to the country as a whole.

Mr. FELDMAN. This next question is not particularly pointed to you, because you are not legally trained, but the Administration's bill, in its declaration of policy, has several substantive provisions.

For example, on page 2, beginning with line 7, where it provides for exception insofar as activities may be peculiar to or primarily associated with weapons and so on, that is a substantive provision, of course, that does not belong in a declaration of policy.

I am not going to ask you to agree or disagree with that because that does involve legislative drafting and it is a legal problem primarily.

Dr. BERKNER. I would only comment, Mr. Feldman, that I think without regard to the provisions of this item that whatever would inevitably emerge from the Space Agency, because of its research and ideas, might also have great military value.

Mr. FELDMAN. What would the payoff be in dollars and cents from such a program? I have in mind, for example, the question of payoff in weather predictions, communications, and so on. Would you care to make a statement in that connection?

Dr. BERKNER. In my opinion almost anything you spend on space research will without doubt be repaid within a period of 10 or 20 years. Thereafter, of course, the research will be producing revenue to the Treasury, and income to our citizens.

Mr. FELDMAN. We have had testimony from the head of the Weather Bureau. He said that the cost to the Nation, because of the lack of precise weather prediction, is in the neighborhood of several billion dollars per year, and that could be avoided if we were able to have the proper weather instrumentation through satellites in order to get adequate weather preduction.

Dr. BERKNER. There is very great hope, as I said in my statement, that instrumentation in satellites will give us a new order of magnitude of understanding of meteorology.

Mr. DURANT. I concur very strongly, not only with the possibility of weather prediction but also of worldwide communications. But in a larger sense our minds are simply deficient, our imaginations are too deficient to try to guess the payoffs of things that we have not yet discovered.

Twenty years ago $E=mc^2$ was of no practical value. But this mathematical relationship was the basis, of course, on which we were able to prove nuclear fission.

Mr. BROOKS. I did not get that statement. Would you mind repeating it?

Mr. DURANT. Our imaginations are deficient, sir, with respect to what we can expect to achieve economically from things that are not yet discovered. I point out that Einstein's equation $E=mc^2$ was of little practical value 20 years ago, but appreciation of this relationship, proved in the laboratory, led to atomic energy which has a tremendous economic potential today.

Mr. McDONOUGH. Will the chairman yield for a question?

Mr. Durant, you say that $E=mc^2$ was a formula known 20 years ago and was not implemented until recently? At the time that it was announced, did we do anything about it except work a few arithmetical formulas out of it?

Mr. DURANT. I would rather have Dr. Berkner answer this question. It was essentially a matter that required research to prove and appreciate. The point is that the economic potential of nuclear energy could not be envisioned 20 years ago any more than we can fathom the potential space research today.

Dr. BERKNER. The equation, $E=mc^2$, has been known through most of this century, but it was not until 1938 that Hahn and Strassman doing some experiments at the Max Planck Institute in Berlin discovered the application of this with the fissioning of uranium. Within a few months after that it was announced that an experiment had been repeated in Washington.

Very quickly the thinking developed. You know the history of the organization, of the work under the National Defense Research Committee in 1939 or 1940 which led to the Manhattan project.

Mr. McDONOUGH. Did the original formula have any reference to a possibility of a detonator ballistic missile or object?

Dr. BERKNER. No, one could not visualize at all from that formula what its particular application would be.

Mr. McDONOUGH. But its first application was in the form of a ballistic object?

Dr. BERKNER. Its first practical application was realized in fission of just a few uranium atoms—fission that could be measured and then grew to the application in the atomic bomb and in the nuclear reactor.

Mr. McDONOUGH. Mr. Durant, do we have, as the meteorologists and astronomers have, a charting of our galaxies? Is it charted similar to the chart of the world on meridian and on longitude and latitude?

Mr. DURANT. The astronomers have been charting these things for hundreds of years. I believe astronomical charts are quite excellent for our immediate needs. Naturally, astronomers have searched ever deeper into the heavens since the time of Galileo.

Dr. BERKNER. The charts are reasonably good except half our galaxy is obscured by dust. We are now charting it with radio astronomy which can see through the dust. However, astronomy has been limited to a narrow band of light wavelengths which can penetrate the atmosphere.

This has restricted our understanding of the universe seriously. As soon as telescopes can be mounted in satellites or in space vehicles or on the moon, which is another satellite, it will be possible to see the stars in the full range of the light which they radiate. It is

25973—58——68

anticipated that this step will give a tremendous boost to our understanding of astrophysics and probably lead us to many practical applications on the earth.

Mr. McDONOUGH. But there is an established charting of our galaxy as far as we can see it?

Dr. BERKNER. As far as we can see it there is.

Mr. KEATING. I would like to follow that up. Practical applications on earth of what kind?

Dr. BERKNER. Just as astronomy and other observational sciences on the earth led Einstein to this formula, $E=mc^2$, which in turn led us to atomic energy, certainly as we learn to understand the physics of the stars, we will develop more formulas representing theories that will lead to broader understanding of nature which in turn will lead to more practical application.

Mr. BROOKS. Proceed, Mr. Feldman.

Mr. FELDMAN. I think that Congressman Keating, when he is talking about practical application, has the same feeling I have. We would like to have that translated for us into something real.

Mr. KEATING. That is right. These formulas are not going to do me any good unless I see them with my eyes.

Mr. FELDMAN. I know that we did not anticipate when the Manhattan project was undertaken that we might get a tremendous payoff in the form of isotopes and other things that we do not know about at the moment but which will certainly come.

We know that we have spent over $14 billion on the atomic energy program so far, and that the payoff in isotopes alone has been more than that and will be considerably more in the future.

Now, when you speak of practical application, can you give us some additional information on that?

Dr. BERKNER. In the field of meteorology, which I have already mentioned, through use of earth satellites, we certainly can see the possibility of understanding the physics of meteorology far beyond what we can possibly comprehend from methods previously available. As we learn to understand the physics of the atmosphere, if it turns out that the atmosphere reacts by the multiplication of very small changes, that is, if small instabilities multiply to form the great weather patterns, then we should be able to get large-scale weather control from the physics of that process.

If, on the other hand, it turns out that the great weather patterns do not originate from these small instabilities which trigger the larger effects, then we should get very high probability of prediction—very high prediction effectiveness.

Therefore, one can almost say with certainty that as we understand the physics of the weather, we either will be able to greatly improve prediction or to get some measure of control of the weather situation. One of these alternatives is almost a certainty.

You will get it one way or will get it the other. One cannot say today which way the situation will go—we must await detailed examination of the physics of the situation which modern instrumentation such as instrumented earth satellites now permits.

Mr. KEATING. That is exactly what I was getting at. Of course, if this could result in weather control, it would be the greatest boon that mankind has ever seen within recorded history, I should think.

Dr. BERKNER. Mr. Keating, I think if it turns out that control is impossible to get but that we can get a high rate of prediction, this also would have a value of many billions of dollars a year.

Mr. KEATING. Yes, it would. I was thinking, comparatively, perhaps the control would be greater unless the control, of course, could be used for destructive purposes as well as constructive. It could loose the greatest weapon that man has ever used in warfare, if you got the wrong parties in control of weather.

Dr. BERKNER. The Russians recently published a very interesting paper in which they calculated that if the Arctic Ocean melted at the present time it would not permanently freeze again.

Now, it is not impossible to conceive of melting the Arctic Ocean in one way or another, perhaps through the scattering of lamp black over the ice so that the reflection of sunlight did not occur from the ice and the sunlight were absorbed instead. It is quite evident that if the Arctic Ocean were melted that the heat interchange between the air and the ocean would be completely different than it now is between the air and the ice which now covers the Arctic Ocean. Under these circumstances one could anticipate that there would be a complete change of weather of the Northern Hemisphere. This is an example of how large-scale change of weather patterns might be brought about.

Mr. KEATING. And they say if it melted it would never refreeze?

Dr. BERKNER. It would not refreeze.

Mr. KEATING. How did it freeze in the first place?

Dr. BERKNER. Because the earth was colder in earlier times. We are just now coming out of the ice age.

Mr. FULTON. It would also submerge New York, San Francisco, and London; would it not?

Dr. BERKNER. It would not if the ice in the Arctic Ocean melted, because the ice in the ocean is floating. Only if the ice on land melts would it submerge the cities.

Mr. McDONOUGH. Only the floating ice converted to water would go in the oceans rather than on the lands?

Dr. BERKNER. If the ice on the Antarctic Continent would melt, then it would raise the water level some hundreds of feet.

Mr. FULTON. And it would be a military capability for the person who could do it?

Dr. BERKNER. Of course.

Mr. BROOKS. Is that a Russian theory you are giving us or is that your own?

Dr. BERKNER. This was a paper published by the Russians recently in which they reach the conclusion that if the Arctic Ocean were melted it would not refreeze.

Mr. BROOKS. Does that have any backing by our own scientists? Does it have any support among our own scientists or is that purely Russian?

Dr. BERKNER. This is purely Russian. The matter has not been examined by our own scientists so far as I am aware.

Mr. BROOKS. Mr. Feldman.

Mr. FELDMAN. We realize now that there is a quid pro quo for any expenditure that we may make in this field. Do you believe that the programs that you recommend are related to the military space programs?

Dr. BERKNER. No, sir, quite to the contrary. I think if the military are not burdened with need of carrying out space programs which are of nonmilitary character that they can get along with their own job better. I think, further, that a research establishment of the kind inevitably visualized by this bill would produce many products which would have military utilization and which the military could use.

I see nothing in this bill which would prevent the military from exploiting any discovery in the field of space which had any military implications.

Mr. DURANT May I interject here that I believe that an extremely close relationship between the military and the civilian scientists must evolve in space-flight research. This teamwork, as characterized by the National Defense Research Council (NDRC) and the Manhattan project of World War II must somehow be repeated in a National Space Agency.

Mr. FELDMAN. One of the most bothersome problems in connection with this bill will be the question of security. I notice that you testified before the House Information Submittee headed by Congressman John E. Moss of California on the question of classification.

Have you any observations or any comments you care to make in this connection?

Dr. BERKNER. It is my feeling that we have already established a sensible pattern in the International Geophysical Year. In the IGY we are exchanging full information with respect to payloads. These are the scientific experiments that are being conducted by means of the satellites. We have certain restrictions with respect to the characteristics of our launching rockets both on the side of the Soviet Union and on the side of the United States.

I would anticipate that within 10 years these restrictions would gradually fall away as rocket technology becomes as standardized as aviation has become over the last 2 decades.

Mr. DURANT. I concur in it Dr. Berkner. There is a vast amount of research to be conducted that, at least at the present, has no security implications.

Mr. FELDMAN. Have the Russians undertaken any declassification of this scientific material?

Dr. BERKNER. Yes, sir. I gave you an illustration of a very considerable declassification of their scientific material in the material that I entered into the record earlier this morning. Moreover, they have declassified the details of some of their rockets.

Mr. DURANT. Five excellent scientific papers on astronautics were presented at the VIII IAF Congress last October in Barcelona.

Mr. FELDMAN. Are you acquainted with any of the details concerning military classification and declassification in the United States?

Dr. BERKNER. Yes, I am quite familiar with many.

Mr. FELDMAN. Have you any comments to make in that connection?

Dr. BERKNER. I believe that insofar as possible one will gain by declassification of both Soviet and United States rocket details. It must be quite evident to all of us that it would be useful to know in greater detail how they made their launchings of their very heavy satellites.

Mr. FELDMAN. Would it help the scientific community to have greater declassification or greater exchange of classified material?

Dr. BERKNER. With respect to the launching of vehicles I would refer this question really to Mr. Durant. But with respect to the pay loads, I think we should keep these entirely unclassified in the space work as they are now.

Mr. DURANT. My comment on that would be that with respect to security on the rocket launching vehicles of our Vanguard satellites, it was pointed out in the President's announcement that all the details concerning satellites, instrumentation and the results obtained therefrom would be made freely available to the international scientific community.

It follows logically that the launching vehicles, because of their close relationship to ballistic missiles and other types of rocket weapons, might be in a security classification status.

Scientists generally would expect in satellite research to be concerned only with the altitude, velocity, g-loading weight and cubic content of the satellite (within which to place instrumentation) and the measurements to be performed, not how the satellite was placed in orbit.

Dr. BERKNER. I think Mr. Durant would agree that there are some forms of launching that would have no military value and can be declassified in the future. For example, launchings which would take place from space platforms might be of the ion variety, or something of this sort, in which they would be very different from military rockets and could be completely declassified.

Mr. DURANT. I agree with that.

Mr. FELDMAN. What is your view as to world opinion regarding United States leadership in astronautics?

Mr. DURANT. I would say that the world opinion at the moment is that the United States is not leading. In fact, I think there is rather a vacuum. The United States led from July 29, 1955, until October 4, 1957. At that time the U. S. S. R. clearly established their leadership, which they underlined on November 3. Since that time of course there have been no launchings by the U. S. S. R. of satellites or announcements, but I think we may expect them in the next few months.

But I believe that this leadership which they still enjoy is dwindling unless they take further positive action. This is the sort of positive action that I recommend to the United States.

Dr. BERKNER. If I could add to this, I would hope that before the end of this year in the field of obtaining scientific measurements in space that the United States might achieve leadership.

Mr. FELDMAN. Earlier in your testimony I believe both of you, Dr. Berkner and Mr. Durant, alluded to the fact that we should not try to match the Russians but to program this thing separately. Would you say that we should try to leapfrog them to the extent of trying to develop a missile—well, first, try to catch up with them in the field of large powered thrust engines and then leapfrog them by developing a spaceship or space vehicle?

Dr. BERKNER. Certainly large thrust engines will be useful in the future and should be developed and as reasonably quick as economics will permit. With respect to a space station, I would prefer withholding comment until this could be given more thorough technical study than has been given to date.

I think there are some serious technical questions which have not yet been completely solved. Certainly Wernher von Braun has given

serious consideration to this matter. There have been a number of other proposals, but I would prefer an independent critical examination of this whole matter before committing the United States to what might prove to be too large an expenditure at this moment.

Certainly we should get on with the study and with all of the research necessary to make the study definitive as quickly as possible.

Mr. DURANT. The development of reliable rocket engines, larger than any we have now, will be required in a few years for space flight. Contracts should be let now for this development.

Mr. FELDMAN. Are scientists of the United States contributing adequately to space-flight research?

Dr. BERKNER. My attitude is that you cannot hold them back. They need only the money and the means to get on with the job.

Mr. DURANT. I would like to comment, purely for the record, on the history of how the satellite experiments were originally judged and chosen for the Vanguard program. Those satellite experiments came out of a meeting which was called in January 1956, at Ann Arbor, by invitation of the Upper Atmosphere Rocket Research Panel, in conjunction with the IGY National Committee.

There were some 30 or 35 experiments proposed by a selected number of invited guests. By no means was the scientific community widely solicited.

Take one example, the area of cosmic radiation. There were many excellent cosmic ray physicists who were never invited or given an opportunity to participate. The same is essentially true of the other scientific disciplines in which experiments were to be made.

I would say that to date, in my opinion, it is simply a matter of modus operandi and an invitation to participate and they certainly would jump at the chance. I think it would be wider.

Mr. FELDMAN. Can you tell us something about the history and aims of the International Astronautical Federation?

Mr. DURANT. This is contained, sir, in the brochure which I believe is to be made a matter of record.

Mr. BROOKS. Let me interrupt the proceedings at this point to say that the bells have just rung. May I ask you two questions at this point. I noticed recently in the Southwest a statement made by Frederick G. Saurma, who is assistant to Von Braun. He said the Russians have fired 16 shots at the moon recently and apparently failed.

Do you have anything along that line?

Dr. BERKNER. I have no information.

Mr. DURANT. I have no information at all, Mr. Chairman. You say he is identified as an assistant to Dr. von Braun?

Mr. BROOKS. That is what this dispatch says—

> Rocket scientist Frederick G. Saurma said last night reports coming out of Russia indicated that the Russians had fired 16 shots at the moon and failed. The assistant to Dr. von Braun at Redstone Arsenal, Huntsville, Ala. * * *

Dr. BERKNER. I have no information. I would refer you to our intelligence agencies.

Mr. BROOKS. Mr. Ford.

Mr. FORD. Mr. Durant, I noticed on the last page of this paper, Commission on Astronautics, Academy of Sciences, U. S. S. R., the listing of the members of the Interdepartmental Commission on In-

terplanetary Travel of the Astronautical Council of the Academy of Sciences, U. S. S. R., some 27 individuals.

Generally, are these men in the older age group or are they in the relatively younger age group?

Mr. DURANT. I would merely guess their average age is in the order of about 40; 35 to 40.

Dr. BERKNER. These extend over this age group and up to the age perhaps of 62 or 63.

Mr. DURANT. As well as down to perhaps 28.

Mr. FORD. In other words, a substantial portion of them have come in the more recent years into the hierarchy, so to speak, of the scientific community through their own accomplishments, as indicated by their appointment?

Mr. DURANT. Yes.

Mr. FORD. Dr. Berkner, on page 3 of your statement you mentioned chromaticity. What is that?

Dr. BERKNER. The range of light which can be seen through the atmosphere. We can see only about one octave of light. If we were above the atmosphere we could see all of the wavelengths radiated by a star or any astronomical body.

Mr. FORD. We could see them with instruments, not with the naked eye?

Dr. BERKNER. That is correct. The naked eye only responds to this one octave that passes through the atmosphere.

Mr. FORD. That is all.

Mr. BROOKS. Any further questions?

Mr. FULTON. I have one question.

Mr. BROOKS. Mr. Fulton.

Mr. FULTON. You commented on the value that further research would have on measurements in space. Actually in addition to weather the measurements of the earth would be a very great gain, would it not, so that we would know the circumference of the earth as well as the location of various points on the earth?

Dr. BERKNER. That is correct.

Mr. FULTON. At the present time, there is no adequate mapping of the earth, nor is there anything in the United States, other than a triangulation system from a point in Kansas, to determine our distances, is that not right?

Dr. BERKNER. That is correct.

Mr. FULTON. We, as a practical matter in science, do not know yet whether there is a drifting of continents and we might be able to determine from a point in space whether these continents are drifting?

Dr. BERKNER. It is very probable that the operation of Vanguard 1 will tell us that in a century.

Mr. FULTON. We also might be able to remove one point of friction and that is how far Washington is from Moscow because we do not know that yet. The Russians think it is one distance and we think it is another.

Dr. BERKNER. We think we know this distance to better than a mile.

Mr. FULTON. But we are not sure?

Dr. BERKNER. We are not sure. With the satellites we soon should know it to about 30 feet.

Mr. FULTON. The Russians think it is closer and we think it is farther?

Dr. BERKNER. We should be able to agree on this.

Mr. BROOKS. May I ask this question: In reference to the control of weather you have stated, as I recall, that is a long-range basic situation. If that is the controlling influence, it would give us an opportunity to better predict further weather, whereas if weather is determined by local vagaries, then it would furnish us a possibility of controlling the weather.

Down in the lower Mississippi Valley I have worked with the Weather Bureau very closely and weather information is vital to us. We just had a 10- or 12-inch rain down there.

Could you elaborate a little bit on that?

Dr. BERKNER. Yes. To try to make it clear, we do not know now whether very small disturbances in the weather tend to multiply and become the main disturbances, or in the event that this happens, which of the small disturbances do this.

Now, should this growth be the case, that is if certain kinds of small disturbances can multiply to cause the real big disturbances, then control should be possible by exercising control of these small disurbances or perhaps generating disturbances of the kind you may want to grow. If, on the other hand, this turns out not to be the case, namely that the atmosphere is not unstable in this way, then we should be able to bring our prediction capability to nearly 100 percent, but we would then find our control more difficult.

Mr. BROOKS. Over a very long period of time you might extend your predictions in the future?

Dr. BERKNER. That is correct.

Mr. FULTON. Mr. Chairman, I should like to insert in the record at this point an article by Dr. Berkner entitled "Man's Space Satellites", which was printed in the Bulletin of the Atomic Scientists.

Mr. BROOKS. Without objection that may be inserted in the record.

(The document follows:)

[Reprinted from Bulletin of the Atomic Scientists, vol. XIV, No. 3, March 1958]

MAN'S SPACE SATELLITES

Lloyd V. Berkner[1]

"Saturday, November 16—Key West 2:55, Savannah 2:57, Atlantic City 2:59, Presque Isle 3:01, Van Horn, Texas 4:40, Dodge City 4:42, Minneapolis 4:44, Pierre 13:40, Fort Smith 13:43, New Orleans 13:45; San Francisco 15:25, Los Angeles 15:27, * * * (the New York Times schedule of Soviet Satellite II).

Thus we are daily reminded that on October 4, 1957, man made his first escape from his imprisonment on the surface of planet earth Even more than nuclear energy, the satellite symbolizes the cohesive force of science in bringing together and cementing political, social, and economic elements of man's civilization. For it shows us science, not as a thing apart from man's daily activities but as an all-pervading force that influences every aspect of human existence—not just man's material welfare, nor his political and military posture, but his humor, literature, and poetry as well. In acquiring his newly won, three-dimensional freedom he is reminded that he enjoys greater opportunity than the simple material existence of the anthill—an opportunity for curiosity, exploration, and comprehension—the intellectual power that makes man more than the ant.

---

[1] Lloyd V. Berkner is president of Associated Universities, Inc., among whose activities are the Brookhaven National Laboratory and the National Radio Astronomy Observatory. He is president of the International Council of Scientific Unions president of the International Scientific Radio Union, and vice president of the Special Committee for the International Geophysical Year, as well as IGY reporter for rockets and satellites.

What is a satellite for?

But just what is this satellite that has hurtled into our view What does it mean to our immediate future? As a simple scientific tool the instrumented earth satellite is a device of superb potentialities, comparable to such other great scientific instruments as the telescope, microscope, or nuclear accelerator. It provides access to secrets of our environment that can be acquired in no other way. For of all the planets, the planet earth on which man lives is one of the most difficult to observe. This is because of man's limited visibility of the earth's surface and his relative isolation. We are sandwiched between an insulating atmosphere above and an impenetrable earth beneath The protective atmosphere above admits but a single octave of light and a few octaves of radio waves from the heavenly bodies. The result is an almost monochromatic view of the universe.

The artificial satellite now permits us to see the universe for the first time in its full range of "color," in the special sense that the satellite broadens the range of our vision from a narrow spectrum of vision to the whole spectrum of nature—from the shortest to the longest wavelengths, from the lowest to the highest particle energies.

But above all, the manmade satellite provides the first step toward man's dream of interplanetary travel, a dream that is now almost realized. Over and above the adventure itself, and quite apart from the unevaluated advantages of occupying other planets, the scientific knowledge to be acquired in such exploration is prodigious. That there are some forms of life on Mars, for example, seems quite certain. The difference in evolutionary patterns under presumably independent circumstances could easily provide basic keys to the origin of life itself. This is but a single instance of a wide range of extraordinary scientific vistas that will be opened to the interplanetary voyager.

What is it?

The satellite itself consists of a polished metal sphere that houses the elements necessary to its successful scientific performance Among these elements is, first of all, the experimental apparatus. Second, the satellite contains a means of recording the results of the experiments. The experimental data recorded and accumulated during each orbit around the earth are best stored in the form of electrical impulses describing these results. The satellite also contains a radio receiver to advise it when to release its stored information and a radio transmitted to convey the information to the ground upon request. This means of storage, interrogation, and transmission is known as the telemetering system. To conserve electrical power, the telemetering transmitter may be designed to act only when properly interrogated by an appropriate radio station on the ground, and, upon interrogation, to transmit its information to a station on the earth for permanent recording. Third, the satellite must contain a radio beacon so that it can be seen in the radio frequency spectrum by appropriate radio receivers on the ground.

Of course, the satellite can be seen visually under certain circumstances—for example, an hour or two before sunrise or after sunset—while it is still illuminated high overhead by the sun. This luminosity can be increased by trailing a large reflecting balloon filled with a breath of gas, or by retention of the final launching rocket. But the latter produces an orbit that will generally deteriorate more rapidly because of the greater resistance of the attached bodies to the surrounding air. Visual observations may, moreover, be obscured by clouds, and, at any rate, are not frequent enough to provide the information needed about the satellite's exact track across the sky. With its radio beacon, the satellite can be seen at any time of the day by suitable radio stations.

The United States version of the satellite is a little more than 20 inches in diameter and weighs approximately 21½ pounds. But compression is only one difficult element of the design of this satellite It must operate in space where, in the shadow of the earth, its temperature may drop toward absolute zero, but, when exposed to the full glare of the sun's rays, may rise toward the melting point. It is extremely difficult to design apparatus for a satellite which can be kept at a temperature at which its components will remain operable Gold has most suitable radiative properties, so that many of the internal components are plated with gold.

What sort of orbit?

The first satellites of both the United States and the Soviet Union travel in a generally easterly direction to take advantage of the earth's rotational energy At the altitude nearest the earth's surface—the perigee—the satellite can be a little more than 150 to 300 miles overhead. (The maximum height at perigee of Sputnik I was reported to be 156 miles.) But the orbit will be usually rather elliptical, reaching distances at apogee usually rather more than 600 miles and for some orbits reaching perhaps 2,000 miles or more overhead. (Sputnik I reached 586 miles at apogee.) In these orbits the satellite will circle the earth once each 90 to 100 minutes—that is roughly each hour and a half—so that it will complete about 14 or 15 round trips each day.

Since information must be repeated back to interrogating stations during each round trip, the earth will receive the scientific information from each satellite about 15 times a day. The earth rotates 15 degrees each hour under the satellite, so its surface advances something more than 20 degrees or about 1,000 miles as the satellite completes a round trip. Consequently, the whole surface of the earth is scanned each day, for a satellite at 300 miles can scan a band more than 1,000 miles wide. In later satellites, as altitude is increased, the period of rotation around the earth will be lengthened. Of course, our only natural satellite, the moon, which is 240,000 miles above the earth, circles it about once each 28 days. It is conceivable that a satellite could be launched at just the right location, altitude, and velocity to cause it to hover almost stationary overhead. Such a satellite would be a few earth's radii overhead. Other possibilities included a north-south orbit passing over the poles so that a satellite would need only 1 interrogating station at 1 of the poles: though without internally imposed correcting forces it would slowly precess from such an orbit. Alternatively, a satellite might be made to follow an orbit along the sunrise-sunset path so that it would be easily visible at all times and could view the sun continuously.

The range of the orbit north and south of the Equator cannot be less than the latitude of the launching site, though it can be more. Thus, the selection of the launching site puts some restrictions on possible orbits. The United States, in launching its satellites from Cape Canaveral, Fla., provides an orbit that scans the earth from about 40° north and 40° south. On the other hand, the Soviet Union is launching its satellites at about 55° north on an orbit that scans the earth approximately between the Arctic and Antarctic circles. But the satellites of either nation could eventually be made to scan the whole of the earth by selection of suitable launching azimuths, though of course some additional launching energy would be required for a north-south or more westerly launching to compensate for the loss of the earth's rotational energy.

What do satellites mean to meteorology?

We learned in high school that the earth's atmosphere can be regarded as the gas of a kind of heat engine that receives a net gain of energy from the sun, mainly from midlatitudes to the Equator. The equatorial region is the firebox and stores much of the energy in water vapor that is evaporated. The atmospheric gas suffers a net loss of energy by radiation poleward from midlatitudes. Thus, the polar regions are the condensers of this great heat engine. The earth's atmosphere is perhaps the only great heat engine that uses a radiator as a condenser.

The transfer of heat from firebox to condenser involves the circulation of the energy carrying gas in the connecting space—the circulation of the atmosphere that brings us our weather. The circulation of a gas over a rotating sphere in this way involves coupling of several successive circulation cells and tends not to be very stable. Unfortunately, the heat input and the output to the engine are not constant. The input changes as variation of equatorial cloud-cover reflects more or less of incident heat from the sun back into space; the output depends on the reabsorption of radiated heat in the atmosphere, as the space-distribution of gases within the atmosphere that reabsorb the heat radiated from the surface is modified. Furthermore, a small change in rate of overturn of the oceans can change the heat supply to or from the atmosphere locally.

Finally, the energy collected by the trade winds and fed into the troposphere through the huge equatorial thunderstorm cells near the meteorological equator—of which perhaps 5,000 normally occur each day—may fail to form locally or may direct energy into the wrong hemisphere to produce temporarily hemispheric unbalance of stored heat All of these localized changes in input and output tend to upset the already doubtful stability of the atmospheric flow.

The circulation of heat from the equatorial regions toward the poles is not as simple as it would be through a series of pipes. Instead, the heat is conveyed through couplings between a series of vertical circulation cells successively in the equatorial regions, in the temperate zones, and in the polar regions in each hemisphere. Sometimes these cells do not transfer heat from one to another as expected, with a resultant delay in the heat transfer and consequent buildup of unusually hot and cold spots, or a rerouting of the ordinary flow patterns. The delay may extend for a considerable time, but when the breakdown does occur, the effects on the weather may be radical or even catastrophic. Such gross effects cannot be traced or understood until the whole earth is observed at very frequent intervals with appropriate measuring devices

The satellite holds promise of revolutionizing our powers of observation in the field of meteorology. Among the early satellite experiments will be the attempt to measure the heat balance of the earth and the variation of the heat balance from place to place by a method designed by Professor Soumi, of Wisconsin This will implicitly involve measurement of the albedo of the earth and the input and output radiation. Not far behind will come experimental mapping of the cloud and storm systems over the whole earth by the method developed by Dr. Stroud, of Fort Monmouth Signal Laboratories This involves delineation of changes and movements of storm systems at frequent intervals, and the observation of cyclogenesis. The location of the hot and cold spots in the sense of excessive input to or output from the atmospheric heat engine is certainly feasible with the earth satellite. It should not be difficult to count thunderstorms or even flash-frequency of lightning on the dark side of the earth or "radio-static" discharges produced by lightning on either the sunlit or dark hemisphere, and to map development and movement of active frontal areas. Moreover, the capability of the satellite to scan the earth quickly, and to store and transmit a large quantity of data on request, will suggest many other powerful experiments critical to meteorology. To what extent do meteoric dust particles of microscopic size vary in density from place to place as they are swept up by the earth as it courses along its orbit? Are such particles of meteoric dust of the kind and numbers that can influence rainfall, as Prof E. G. Bowen has suggested?

What about solar radiation?

We usually think of the sun as a fixed star. In fact, the visible radiation from the sun is defined in the terms of a solar constant based upon radiation transmitted through the atmosphere. But radiation of short wavelengths, the ultraviolet and X-radiations from the sun, are absorbed in the high atmosphere and cannot be seen even from the highest mountaintop. Fleeting rocket observations have shown very large variations in solar radiations at such short wavelengths, variations that are more than 100 to 1 even when the sun appears quiet. With only minor visible manifestations such as small eruptions in the sun's chromosphere, the IGY rockets have found an immense increase in ultraviolet and particularly X-radiation, so that X-ray wavelengths as short as 1 Angstrom penetrate deep into the atmosphere and can be seen only 35 miles overhead. Clearly, it is important to understand the character and variation of these otherwise invisible radiations from the sun. This the satellite can do superbly with spectroscopes or simple telescopes with banded filters. By continually recording the radiation of the sun from a vantage point outside the absorbing atmosphere, the satellite can provide us with a complete story of the character and intensity and variation of solar radiation in the whole radiative spectrum. Where this knowledge will lead no one can say

What can we learn about the exosphere?

The exosphere is the region of the atmosphere extending outside the level of the outer or F-region of the inonosphere more than 250 miles overhead Ordinarily, radio observation of the exosphere is not possible because of the shielding of the intervening ionosphere. Yet there is increasing evidence from many sources that the exosphere plays an important and interesting role in our general environment. It is a region traversed by primary cosmic rays where they are deflected by the geomagnetic field. It is the region of first impact on our atmosphere of streams of solar corpuscles ejected by the sun that produce geomagnetic disturbances and auroral displays when intercepted and deflected by the magnetic field of earth. It seems very likely that the sun's corona extends through the earth's orbit, so the exosphere is actually the region of coupling between the corona and the earth's atmosphere.

Quite aside from these classical examples of the influence of the exosphere upon our environment, recent studies of that strange phenomenon known as "whistlers" have greatly stimulated our interest in that region. Whistlers are electromagnetic waves of a very low frequency—a few thousand cycles—that were first heard on telephone lines in the Alps in 1886. Whistlers arise from lightning flashes whose resultant field appears to travel through the exosphere far into space. In the presence of tenuous ionization of the exosphere, they are propagated along lines of force of the earth's magnetic field, following the field down to the opposite hemisphere where they are reflected back over the same path to the point of origin. Thus, they are heard sometimes with many successive multiples, spaced by a second or two of time, as they bounce back and forth between one hemisphere and the other. As many as 15 or 20 successive multiple reflections have been observed. Strangely enough, a late multiple, perhaps the 5th or 10th, is often stronger than the original whistler, as though the wave were amplified as it traveled. Particle streams from the sun, acting as a cathode and intercepted by the earth, are focussed in the earth's magnetic field to form a kind of traveling wave tube amplifier. It happens that whistler waves traveling in the exosphere are propagated at the proper velocity to acquire energy from the incoming particle streams, and seem thus to be actually amplified as the solar streams of particles enter the exosphere. Moreover, the impact of fronts and irregularities of the particle streams themselves on the exosphere appear to generate low frequency radio noises that are identified as "hooks" and "hisses."

The whistler is only one example of the influence on our environment of the exosphere where the atmosphere and magnetic field of our rotating earth is coupled to the contents—the fields and particles and debris—of surrounding space. The satellite provides us with means of studying this external region. By means of proton magnetometers or similar devices, it is possible to measure the strength and direction of the earth's magnetic field at great heights. It should be possible to ascertain directly whether this field is distorted at great distances above the surface as it is coupled to the particles traveling through the space of the earth's orbit. It will be possible to ascertain whether the deflection of incoming streams of particles, under the influence of the geomagnetic field, form ring currents that may encircle the earth, and to measure the intensity of such ring currents when they appear. The role of incoming particle streams in forming the aurora can be studied at first hand and the changing spectra of the aurora extending into the X-ray spectrum can be observed as aurorae develop. It should be possible to carry out experiments in the very regions where the traveling wave amplifier is operative

The satellite can make direct measurement of the energy and intensity of incoming particles and particle streams including both soft and hard primary cosmic rays The cosmic ray experiments contemplated for the satellite experiment involve continuous recording of cosmic ray counts. For this purpose a magnetic tape recorder, weighing only about 6 ounces, has been devised to register this information and to repeat it back to the interrogating telemetering station

What else can satellites tell us?

At this point we should consider some of what might be called the "free" experiments that can be done by the satellite These are experiments that require no special instrumentation, but only observation of the satellite orbit and its perturbations The first of these is the measurement of atmospheric density at the great heights at which the satellite will travel. Density can be derived directly by measuring the rate of acceleration of the satellites along their orbits. As a satellite loses energy to the surrounding tenuous atmosphere, its height diminishes, but of course its orbital rate increases in the smaller orbit. As it slowly descends into more dense atmosphere, it will distort and heat behind an ever enlarging air-cap until its burns out brightly in a slowly descending path. Atmospheric parameters are of the utmost importance to the life of the satellite, since the higher the density the shorter the life The uncertainty of atmospheric parameters at the levels of proposed orbits makes it difficult to predict what the life of a particular orbit will actually be until more experiments have been completed and evaluated But it now seems safe to predict that with the perigee of the initial orbit above 300 miles, the lifetime will be several years.

A second free experiment involving observation of the successive positions of a satellite relates to geodesy. Here, two distinct aspects of the orbital motion must be considered—the dynamical and the geometric. The dynamical observations involve observation of the perturbations of the satellite orbit on successive

rotations to deduce something concerning gravity anomalies. In connection with other information, these observations can tell us a great deal about the distribution of matter within the earth. By the geometrical method, that is the accurate observation of the satellite in a number of positions along the same or successive orbits, we can derive direct information concerning the shape of the geoid, and the precise location of the points over the surface of the earth with respect to one another. The accuracy foreseeable by these methods should permit us to establish within a reasonable space of time, perhaps less than a century, whether movements of the earth's crust or continental drifts actually occur. In this way, direct evidence relating to convection in the earth's interior can be derived.

Another "free" experiment relates to the determination of total ionization in the exosphere between the ionosphere and the level of the satellite. At low altitudes in the sky, while the satellite is rising, the waves from its radio beacon must pass through the ionization of intervening space in such a way that they will be refracted toward the zenith. Therefore, near the horizon the satellite will appear to the radio receiver to be higher in the sky than it appears by direct visual sighting. Near the zenith, this difference disappears. When the angle between the radio and visual position is measured at a known altitude, the total ionization between the earth and the satellite can be readily computed, since refraction of the radio waves by ionization has caused the radio sighting to be elevated. If one subtracts the ionization between the earth and the level of maximum ion density of the ionosphere—which is known from other radio measurements—we shall have remaining the total ionization between the ionosphere and the satellite itself. At a given station on successive orbits the satellite will appear at different heights ranging successively from 300 to perhaps 2,000 kilometers with the precession of the nodes, so that such a succession of measurements should provide the numerical distribution of ionization through the exosphere.

Some of these measurements have not been possible on the early Soviet satellites because of the low radio beacon frequencies of 20 and 40 megacycles. The strong and unpredictable refraction of these low wave frequencies in the ionosphere do not permit sufficiently precise measurements of location to establish the orbit with the needed precision. But on the other hand, since the 20 and 40 megacycle wave frequencies are near the initial penetration-frequency of the ionosphere, and since the sputniks plunged through the F-region of the ionosphere when they approached perigee, interesting new properties of the ionosphere have been deduced.

Among other possible experiments is the measurement of the gravitational redshift. This general kind of experiment is mentioned in the paper on the Russian satellite transmitted to me by Academician Bardin. In the study of many basic aspects of science it is of vital importance to determine whether the gravitational redshift is observed as supposed from theory. The whole question of the properties of time as it enters dimensionally into our theories depends on the outcome of such a test. One way of undertaking this test, being considered in the United States, would be to compare the relative time kept by two atomic clocks—one in the gravitational field on the surface of the earth and the second one high above the surface where the gravitational field is significantly weaker. Using the atom of cesium, Professor Zacharias of MIT recently has developed an atomic clock which is potentially capable of keeping time to at least one part in 10^{12} (a billion billion). Although this precision has not yet been fully achieved (present clocks keep time to a part in 10^{11}, a hundred billion), the realization of a light-weight atomic clock of the required quality seems feasible within the next few years With such precision of time made possible by the atom, the erection of one such clock in the earth satellite would permit the direct conduct of the redshift experiment by measurement during a single, or at least a few complete orbits.

A second experiment involves the mounting of optical telescopes on the satellite itself. This was suggested to me some years ago by Professors Spitzer and Schwarzschild at Princeton. The satellite is actually a highly stable base that can be rotated through tiny angles on the quite frictionless bearings of the surrounding vacuum and controlled with the greatest precision by a mere breath. Not only is such control not difficult when referenced to positions of fixed stars, or points on the earth, but it is generally easier than the control of conventional telescopes on their awkward mounts. Such telescopes can work over enormous frequency ranges, or spectra, of "light," compared to our vision from the surface of the earth where the width of spectra now observed through the

atmosphere is very restricted. This possibility of looking at distant stars, and galaxies, and galactic groups in their full range of color opens a whole new vista to the astrophysicist in his study of the processes of the creation and ultimate destruction of matter. Within relatively few years, telescopes of a size equivalent to the largest telescopes on the earth can be arranged on instrumented earth satellites so that the full information that the universe provides will become available to man.

What about space technology?

In view of the satellite's great significance the question of the organization and administration of space technology becomes a matter of crucial importance. Specific plans for scientific satellites are now projected only during the Geophysical Year. Looking to the future, the United States must make a number of clear decisions of policy. First, will it press forward in space technology as a matter of policy? If it does, will it do so in isolation by within national limits, or will it join its space efforts genuinely with other nations through joint laboratory and launching efforts? Since not many nations can sponsor an independent space effort, a policy of isolation would exclude the opportunity for capable and energetic scientists of smaller nations from their aspirations to contribute to space technology. If international effort is undertaken, should the United States sponsor such effort under the auspices of a group of friendly nations, or as a complete world effort in which all nations are involved?

Whatever international courses are chosen, the character of our internal organization is of vital concern. One might argue that space technology should be developed under the wing of the military services Undoubtedly, the satellite has military implications of its own, quite apart from the military capabilities implied in the ability to launch it. Moreover, the great rockets required to launch heavy satellites are available from the military stockpile, and at the moment the greatest skills in rocketry are under the supervision of our Department of Defense. Consequently, it might be thought that greater economies of effort could be achieved in this way. Certainly strong arguments can be advanced for military control of future satellite development. But these arguments have a certain superficiality that misses the significance of the satellite as a social development The extension of geography into space should be a peaceful project, as President Eisenhower has advocated Just as the initial planning for satellites for man's benefit was conducted in the friendly atmosphere of international scientific circles, so the future international discussions of space programs should be free of the rigid domination of the uniforms of the world

This is not to say that the military organizations should not play their part in the conquest of space. Certainly, they have many skills and facilities that are needed, and they have a legitimate interest in the subject. But space conquest should be primarily for intellectual and social rather than military ends. We must recognize our conquest of space as a superb manifestation of man's control of his environment that far transcends its incidental military relevance to the interrelationships of men and nations.

Who should control United States space plans?

Our Nation faced a similar decision in planning the future of nuclear energy. Nuclear development has a relation to military strength at least equal to that of space technology Yet our decision, and I believe it was right, was to place its direction under a civilian agency, the Atomic Energy Commission. For nuclear energy had civil and peaceful as well as military implications. Whatever the defects of that organization, no one would suggest that it has in any way hampered the growth of United States military strength On the contrary, our nuclear military strength is in the unquestioned vanguard of our national scientific achievement At the same time, a civilian AEC provides the mechanism through which "atoms-for-peace," and other friendly international activities sparked by the atom can aid in breaking down international tensions.

Similarly, the full scientific and social potentialities of space technology, in my opinion, can best be realized under a civilian Federal agency. The direct consequences of carefully designed space researches will react on every aspect of man's existence and will radically influence his adjustment to his environment. The purely scientific problems involved are complex and their solution can be best achieved under civil auspices closely related to the academic atmosphere, because they transcend the normal limits of military technology. Even the advanced rocket techniques that are needed must presently far outstrip the military

needs, and in fact, will often differ radically from military designs. Certainly great laboratories will be required, and these should enjoy the intimate relationship to university activities that grows out of broad civil direction of national programs.

In the present state of unstable military equilibrium, it is natural that we should be concerned for our military strength and effectiveness. With the gravest consequences at stake, no nation can afford to tip the balance adversely by weakening its military strength. But in facing the future of space technology with a biased emphasis on its military aspects, there is danger that we may fail to grasp the real opportunity for world leadership that space technology offers. Militarization of broad problems such as space technology that affect all elements of our national community suggest a considerable danger of our Nation succumbing too completely to a psychology of military direction and control Instead, a more balanced approach is needed through which all elements of our society—including the military—have an equal opportunity to contribute. We must not forget that it was the Soviet Academy of Sciences and not the Red Army that negotiated the plans for the launching of the first earth satellites.

The challenge of the earth satellite will not be simple to meet, nor can it be met by passing off responsibility on some special group, or by seeing the challenge solely in military terms. It is an instrument that enables man to view his problems in new perspective and provides him with incalculable advantage. Space technology represents a broad intellectual challenge that must be met with an equally broad response from all elements of our national community. We must plan so that wisdom rather than expediency dictates our course.

NOTE.—This article includes material drawn from a special convocation given at the University of Maryland, December 11, 1957, and from the IGY Manual on Rockets and Satellites, Annals of the IGY, Pergamon Press, 1958, edited by L V Berkner, et al.

Mr. BROOKS. If there are no further questions, the committee will adjourn until 2:30 o'clock this afternoon. I want to thank you gentlemen for coming before this committee and giving us the benefit of very fine testimony.

Dr. BERKNER. Thank you.

Mr. FULTON. I join in those thanks.

(Whereupon, at 12:20 p. m., the committee recessed to reconvene at 2:30 p. m., the same day.)

AFTERNOON SESSION

Mr. McDONOUGH (presiding). The committee will be in order.

The next witness is Dr. Walter R. Dornberger, technical assistant to the president, Bell Aircraft Corp.

Doctor, we are very happy to have you appear before us. It is a pleasure to welcome you.

STATEMENT OF DR. WALTER R. DORNBERGER, TECHNICAL ASSISTANT TO THE PRESIDENT, BELL AIRCRAFT CORP.

Mr. McDONOUGH. You may proceed, Doctor.

Dr. DORNBERGER. Mr. Chairman, and members of the committee and counsel:

I feel privileged to have this opportunity to talk to you about my ideas on space flight and to present my conception of the organizational requirements this country needs for the coming space age. These are subjects with which I have been concerned long before a sputnik appeared.

As you may be aware, I have had some experience in this general field, gained originally in Germany during the years 1930–45. I am

also aware that an organization such as operated during that period in Germany could not be applied here and would not work in the United States today.

I would like to begin by telling you something of the German operations, then explain my thinking on approaching the program of utilization of space by the United States for man, and finally, I will offer suggestions for a space organization effectively encompassing the interests of the scientists and military and other Government agencies. For the purpose of time, let us say that my remarks will be confined to what may transpire in the next 20 years.

The German interest in space flight was strictly military. That meant the Germans wanted to use very high altitudes and very high speeds in order to stay outside the effective range of conventional defense weapons. The German scientists and Government agencies, for the most part, were not interested at all in anything beyond the atmosphere.

When the effort was begun in Germany by the military establishments, all the tools available, such as powerplants and guidance systems, were primitive and of no use. There were many ideas and theories.

Ideas—we had lots of them, but everything else was missing. Since military importance was recognized, secrecy was our main concern. With the Treaty of Versailles in force, and the close international connections of our industry a fact, it was impossible to start such a project in public.

It had to be done in military establishments in all secrecy.

In 1930 at a time when I was a captain in the German Board of Ordnance—I was put in charge of what we call presently in the United States ballistic missile program, but at that time, was called rocket development. I was in charge of rocket development for the army and air force. The navy was not then interested.

The only one military requirement I ever got from my superior was very short, in all, eight lines. I received full responsibility and at the same time full authority to do the job as I saw fit. For the first years, I had to report only to the Chief of the German Board of Ordnance; from 1943 on, to the Chief of the German Military High Command, and from 1944, only to the Chief of the German Reich.

During World War II, the interest of the air force and the navy grew rapidly in this field and each started its own projects, but after a short time of what can be best described as highly organized confusion, a different approach became obviously necessary.

The first step was my assignment to what we could call in this country a guided missiles czar. All army, air force and navy departments associated with our projects were placed under my command. My field of operation was wide and included research and development, production, training of troops and supply of all three armed services. And, gentlemen, since we in Germany were then living under a dictatorship, there was never any question of the complete unification of the armed services.

Regardless of their basic service, all military and, for that matter, civilian personnel reported directly to me and I had the authority to promote, demote or fire them. There was no such thing as one of my organization reporting directly to a former superior.

By this concentration of effort on the part of all military services, any possibility of a duplication of effort was avoided. My entire staff, which had the responsibility for all missiles and solid and liquid fuel rockets, never numbered more than 150 men.

Our aims were weapons and weapons systems. Almost all research was applied research. Only approximately 10 percent of the research effort went into basic research. Since I did not have to ask anybody about what to do, decisions could be made fast and redtape was reduced to a minimum.

There was only one office in all the military establishments responsible for the entire program. That was my division; and since I gave trustworthy people enough authority to act, I was free for technical decisions, for planning and organization.

Since I remained in this position without even a thought of rotation for almost 15 years, the necessary steadiness in the development of such new weapons systems, which comprise in their design all branches of science and technology, was guaranteed.

Development work in the German guided-missile program was handled by the industry, which is the case in this country also, with one exception, the long-range ballistic missile. Here, research and development was done at Peenemunde, a strictly military establishment organized along the lines of a private enterprise. Salaries and wages equaled those paid by industry and the administrative setup was the same as in any private factory. Only a few officers held the key positions.

For the research and development done at Peenemunde, I should mention the fact that the military alone had the very expensive, the most appropriate and most modern facilities to get the job accomplished.

While most of the component development was done in the industry, Peenemunde did the preliminary design work, the weapon system work, the coordination, the assembly, testing, and firing.

In the research field, we first believed we should do everything on our own for security reasons. And only when time became an important factor did we call the scientists in to help us in the solution of specific problems.

It may be of interest to you to learn how this military establishment handled the ever-delicate question of relationship between the military and the scientist.

Frequently, at Peenemunde, it was necessary to obtain answers to problems encountered during the development phase of a weapons system planned for military purposes. We defined precisely, and in as few sentences as possible, the particular problem.

The scientists were requested to solve that problem and only that problem. They were never allowed to argue about it or to philosophize about the project in its entirety. An answer, clear-cut and to the point, in the shortest possible time, was what was wanted—and provided.

Scientists did not run our program, they just helped us.

Another facet which ran smoothly was budgeting. Since I was my own superior, a very unique circumstance, to be sure, this problem was much easier to solve then similar problems in this country.

25973—58——69

I was commander at Peenemunde and at the same time, division chief of all rocket development in Berlin. In this latter position I was also superior of the Peenemunde establishment and authorized to grant any amount of money needed.

It was easy for me to sign the annual check for Peenemunde, after I had argued with the people in Peenemunde about the amount.

Whether at Peenemunde or any other place, it is of the greatest importance for the success of advanced technical programs which run for periods of 5 to 10 years, or even longer, to be assured of sufficient funding on a sustaining basis. The yearly fight for the budget takes too much energy and time from key personnel who should be concentrating on technical matters and not devoting efforts on basic administrative problems.

Progress in any program recognized as necessary and vital should not be interrupted.

I hope that these preliminary remarks demonstrate that there can be no comparison between the status of a high priority project in Germany under a dictatorship during wartime conditions and the present situation here in the United States.

The beginnings of the space age at Peenemunde certainly have had tremendous influence on this subject by all governmental agencies, the industry and the military in this country.

But here in 1958, the problems of how to organize effectively for this technical new era are not simple by any means. However, I believe certain fundamental ideas can be well adapted for our present-day use.

First, and in my opinion this is mandatory, we must have a plan for what must be done first. Second, we must define how space can be best utilized for the national interests of the United States.

Let me cover the second problem first. Since 1942, when the first V-2 was launched, there has existed a fourth medium of travel, in addition to ground, air, and water.

A medium which can be used by man for different peaceful and military purposes. I refer, of course, to the medium of space.

I don't think I have to take time to enumerate the various ways in which space travel can be utilized. But, briefly, for the military, space flight means the expansion of the field of operations of the Armed Forces more and more into the vertical dimension; for our Government and for our Nation, space flight means prestige; for the scientists, a vast increase in knowledge in many exciting fields.

I believe that at present, and for the time period I am talking about, cislunar space will be the only new additional field of military operations. To really conquer, occupy, keep, and utilize this part of space during the coming 20 years should be the military's main interest and objective in space.

Anything beyond that, for the same time period, is only of political (prestige) or scientific interest.

I believe by accepting this thinking about the zones of interest, the areas in which each one should concentrate becomes easier to define. Cislunar space, which will become of tremendous importance for our national defense within the next 20 years, should be the main realm of the military, translunar space that of the scientist. When prestige is involved, the Government should decide which one should take the lead.

When the scientists have the responsibility, the military should help, and vice versa. No duplication of effort and facilities should be necessary or tolerated.

It is my personal opinion that space will be conquered and utilized by man and man alone—and not by automatic machines. Certainly, automatic probing devices have to precede manned flight into space. But only to obtain the scientific data necessary for later manned space flight operations.

We have to balance very carefully the high cost of automatic space devices with the gains reasonably to be expected.

Looking at space flight and the utilization of space for our national interest, I think we should be aware that three fundamental prerequisites are necessary:

(1) The question is no longer one of sending several thousand pounds into orbit or several hundred pounds to the moon, but rather to get 20,000 or 30,000 or more pounds at a particular spot in cislunar space. In order to achieve this, we urgently need the development of high thrust powerplants, able to deliver substantial tonnage into space. High energy propellant and nuclear powerplants should have top priority. And to expedite quick results we should make up our minds what type of high energy propellant is the most desirable and concentrate on it.

(2) Space will be ours only when we are able to maneuver in it. That means the ability to change our course and to increase or decrease our speed at will. In order to avoid excessive takeoff weights and highly complicated overall systems, we need:

(*a*) a lightweight space engine for which the necessary energy will be taken out of space, for example ion rockets. Ion rockets are still in the laboratory stage, but we need them urgently.

(*b*) we need an on-board navigation and guidance system by which we know at any time where we are, where we are going and at what speed. We cannot wait during a flight until ground stations or a system of artificial satellites tell us where we are. This navigation system has to be coupled with a sub-miniaturized computer, so that the necessary corrections can be made according to the reasoning power of the man. Up to now, this navigation system does not exist.

(3) We must solve in practice the problem of a safe return to a predetermined landing strip after a flight through space. I think it is foolish to start with a flight to the moon and then try to come back. We should use a step-by-step approach, going higher and faster every time and making sure that our crews will come back safely to earth. We have theories enough, but have none proven yet in practice. This problem area should be another main concern in the coming years.

All other problems of space flight are of relatively minor importance and will be solved without requiring any additional major scientific or technical breakthrough.

Now, may I discuss some basic principles for our planning—planning which will give us a clearcut, expeditious program for the conquest and utilization of space.

In 1942, the Germans had conceived by a step-by-step approach, and many of its aspects are still valid today.

A certain overlapping in the development of different steps will be necessary, especially in view of the increasing time for development

of each succeeding step. Applying this realistic step-by-step approach to usable space vehicles as a guide, all necessary research effort and the development of needed component parts can be initiated on time, and all more or less fancy and premature projects can be eliminated.

Now as to my conception of a step-by-step plan for space flight, I must acknowledge that some preliminary phases are already under way. But for the purpose of illustrating what I consider an orderly plan, I would like to list these steps:

1. Automatic single-stage ballistic rockets, as for example the V–2 and the Redstone.
2. Automatic single-stage rocket glider, such as the A–9 in Germany.
3. Manned single-stage rocket gliders such as the German A–9B and the United States X-series, the X–1, X–2, X–15, and so on.
4. Automatic multistage long-range ballistic rockets such as the Atlas and Titan.
5. Manned multistage, long-range hypersonic rocket gliders like the Dynasoar series.
6. Automatic satellites, such as the sputniks, Explorers, and Pied Pipers.
7. Manned ferry rockets to a satellite orbit, extending up to the moon.
8. Manned satellites, recoverable or permanent.
9. Automatic space vehicles.
10. Manned space vehicles.

I think we are well on our way to the automatic satellites. First prototypes are up in space, bigger ones will follow. I am quite sure we will soon solve the problem of accuracy, but since these bigger satellites will stay in space over quite a period, months or even years, and spaceships will be on their trips for weeks and months, we may not be able to solve the problem of reliability. No automatic, complicated, unattended device such as a large satellite will work satisfactorily in space for the operational time we are talking about.

With the high costs of these satellites, we have to get human beings up to adjust, repair, and to exchange the equipment, and we have to get the crew back. The same problem arises when we have to use the moon as a satellite. Therefore, the next natural step after the big satellite is a ferry rocket to deliver the crew and the material to any permanent satellite orbit and get the crew back.

Other problem areas which should be included in our planning is our armanent in space. This will be of major importance since many weapons used in the atmosphere won't work effectively in space.

Another problem will be space technology. Our equipment is built most of the time for terrestial use. In space, there is a different environment in which this equipment has to work. All conditions in space cannot be simulated on the ground. We have to get up in space with a kind of flying testbed or flying space laboratory, to make our investigations conclusive.

In my opinion, the Dynasoar program, which the United States Air Force has under consideration now, will help us tremendously in this respect. It merits all the support it requires.

Space flight is of the utmost importance to the future of our country. And in our efforts to conquer this medium of travel, we must not let ourselves be panicked into undertaking new projects before we have solved the challenges of the preceding step.

I do not mean to say that development of main components has to be on a concurrent basis. But I am opposed to "wild blue yonder" schemes which could divert us from the more vital business at hand.

I am also opposed to setting up an all-out crash program to conquer space with spaceships right now. Too many unknowns are still existing. We have to create first of all the tools we probably need. A realistic step-by-step approach is better than rushing ahead forcefully and then later having to retrace our steps.

Now, how can we organize for the coming space age here in this country?

Two main principles should govern us:

(1) Any duplication of effort must be avoided.

(2) Someone, preferably an individual, has to make the final decisions.

Several groups are concerned with space conquest.

There is the interest of the scientists, who want to explore space in order to increase scientific knowledge, there is the interest of the Government, for example, the Department of State, which wants to increase our national and international prestige, and there is the interest of the military, who may have to fight wars in and out of space.

These interests are bound to collide.

There must be an agency with distinct power for decision on the very top, even at the Presidential level.

Such a Space Agency could perhaps be directed by another Vice President. I am told that the President might use more Vice Presidents to help him run the country and a Vice President of Space could be a good office to start expanding the second level of our national administration.

Of course, you understand I say this to help illustrate how important and how high in the administration I think my suggested authority on space matters should be.

This Agency would give the green light for any major space project, would decide who should run projects which may be needed, for instance, only needed for national prestige reasons.

This Presidential Space Agency would also coordinate the efforts of any or all other agencies interested in space. These would include the Secretary of Defense, and if you will permit me to envision for a moment, perhaps even a Secretary of Science.

According to my ideas, a Secretary of Science could effectively and justifiably be the organizational head of the National Science Foundation, National Academy of Science, and other scientific establishments.

The Space Agency at the Presidential level would have the full authority of decision making, not just an advisory function alone. It could be small in size, since no studies should be made by this group.

Research facilities should not be duplicated. I think that the plan to expand the field of the National Advisory Committee for Aeronautics to take care of space research also is an excellent idea. But this new National Aeronautics and Space Agency, as recommended by the President, should not try to develop its own space vehicles or to run projects. NASA should serve as a basic and applied research facility only, and should serve the scientists as well as the military. It should have no authority to decide about a project.

Direct and close cooperation between the two main scientific and military agencies and the expanded NASA is mandatory. But any difference of opinion between these agencies which are to lead the United States into the space age, should be straightened out by the Space Agency on the Presidential level.

In their field of interest, the Secretary of Defense, as well as my suggested newly to be established Secretary of Science, should have full authority.

And as just a word of caution—or precaution. In each department, that of defense and of science, there will be dozens of subdepartments and suboffices which will want to have an important word on the space age.

These departments and offices should be held to a bare minimum, if not eliminated from a voice at all.

Time and well-conceived action, not words and paperwork, are the main considerations now.

I am convinced that with close cooperation between the two main participating agencies and the NASA, duplication of effort can be avoided, and steady progress made toward a dominant role for the United States in the space age.

Thank you.

Mr. McDONOUGH. Doctor, judging by questions and comments made by members of the committee during the hearings that have been held to date, it is evident to me that quite a few of the members, if not all—though I am not speaking for all—appreciate the significance and importance of your recommendation about a Department of Science.

Any bill that is reported that does not provide for the establishment of a Department of Science will not be because the members failed to recognize the significance of your testimony and others in that respect, but due to the separation of powers that we have under the constitutional government.

While Congress could force through a law establishing a new department, it would be a matter of wisdom whether that should be done until a President, whoever might be in the White House, was willing to recognize the fact that such a department, or any new department, should be established.

You understand that.

Dr. DORNBERGER. Yes.

Mr. McDONOUGH. Profound consideration by Members of the Congress should be given to the views of the President in all matters, particularly with respect to enlarging the President's Cabinet. Even without the Cabinet status by law, the President can invite one to sit in with the Cabinet and to occupy what, in effect, would be Cabinet status. So, if we report out a bill that does not go that far, we would not want you or other witnesses to think that we are ignoring your views and your opinions in that respect.

However, there are other factors that face us under our constitutional setup which you appreciate, I am sure.

Dr. DORNBERGER. Mr. Chairman, I am 100 percent with you. My proposal basically is merely to put an organization within the organization that we have. An additional and special organization to concentrate on space. It matters little what name this organization

bears as long as its function is clearly defined. I am not suggesting changing the constitutional organization in this country.

Mr. McDonough. I think, in my mind, it is just in the future, it is just a matter of time, when there will be a Department of Technology or some similar department.

Mr. O'Brien.

Mr. O'Brien. Doctor, I want to compliment you on your very fine statement. I understand in the fraternity, you are considered to be the "elder statesman," so we should regard carefully what you have said. You have made it clear that you believe the director of this Space Agency should hold an exalted position, very high in the Government. Do you have any ideas as to the type of man who should fill that exalted posititon? Should he be a scientist?

Dr. Dornberger. Not necessarily. He doesn't have to be either a military man or a scientist.

He should be a man with a lot of experience, a lot of commonsense, a man who is able to understand the language of the scientist, to set goals to the scientist and to supervise scientists, a man who is able to run, administratively, very difficult jobs, and a man who understands and can fulfill fiscal requirements and can secure essential funds.

Mr. O'Brien. He would have a great deal of authority over the military, too?

Dr. Dornberger. Yes. The man I propose in my organization should have complete authority. Since we will have different departmental interests, such as the military, scientific, commercial and communication, we must have a man at the very top able to make decisions when and if interests collide or duplication of effort is evident.

For instance, the Secretary of Defense is primarly interested in military applications. The Secretary of Science, or the scientific departments, are naturally concerned only with scientific achievements or those achievements which contribute to national prestige. Serving both of these organizations, purely from a research standpoint is the NASA. The scientific and military interests unquestionably would collide. NASA should not have the authority to intervene except in research matters. There must be a higher authority, someone on top to make the final decisions. There could be no efficient setup for a space agency which does not have authority at the Presidential level.

Mr. O'Brien. I notice you stated that in the project which you headed, approximately only 10 percent of the research effort went into basic research.

You saw the urgency of the problem at that time as being a military problem.

But it would be your idea that the director would be the one to decide at a given time as to what percentage went into basic research.

Dr. Dornberger. Yes.

Mr. O'Brien. I would assume that times being as they are now, that 10 percent would be probably a small percentage. It would probably be something larger than that.

Dr. Dornberger. Before answering the question, I think we should define what is basic and what is applied research.

Personally, I think when our problem is primarily to get into space, then all research work for this purpose is applied research.

Mr. O'BRIEN. I notice that you mentioned that you remained in your position for 15 years, or almost 15 years, without any thought of rotation. Do you believe that this high official should have a long term, too?

Dr. DORNBERGER. Yes. I think so. As an example, I refer you now to Gen. Bernard A. Schriever, commander, Air Force Ballistic Missiles Division. General Schriever has been in his position for about 4 years and it is reported that he is eligible for reassignment. A man barely gets acquainted with the problems of a position such as his in 4 or 5 years. Abruptly we transfer all of his experience and substitute a man who can be completely new in the field. He may have new ideas, a new philosophy and may change many things detrimental to smooth progress. In such an important job, tenure is almost as important as experience.

Mr. O'BRIEN. Our primary job here, as I understand it, is to get this Space Agency off the ground. I think that we are concerned with the powers that it would have. But would you not think that first we should create a strong agency, with a responsible man on top or a man with full responsibility at the top? Then, on the basis of their first year of operation, perhaps, consider your other point concerning the continuity of appropriations?

I noticed you made quite a point of the hit-or-miss business on appropriations. You would not suggest that we try, in writing this legislation, to cover that whole subject at this time; would you?

Dr. DORNBERGER. Well, not necessarily. However, we must keep in mind that the projects we are talking about can run into decades before they are completed and continuity and funding is a prerequisite.

I would like to make a further comment about NASA, which is the only logical research organization in the Space Agency, as I see it. NASA should be the one and only research organization, with the best and most extensive facilities available. But it should be a research organization only and should not do development work of its own.

If NASA were to do its own development work, as proposed in this bill, there is a possibility it could concentrate its efforts entirely on its own conception of space travel. This conceivably could eliminate its consideration of the projects of other interested agencies. If NASA is to be a true research organization, it should stick to research and provide research for all the developmental agencies—a big enough job in itself. Otherwise, we will find ourselves in the position of having the developmental agencies doing their own research as well as their own hardware.

Mr. O'BRIEN. I have one other question. We have had some discussion from time to time about the desirability of feasibility of sending a manned rocket into space for 150 miles. It has been suggested. I notice you said you think it is foolish to start a flight to the moon and then try to come back, but you should use the step by step approach. I am inclined to agree with you. Do you think it would be a stunt like shooting a woman out of a cannon to experiment first with sending a man in a rocket, say, 150 miles in the air and getting him back?

Dr. DORNBERGER. No; I think not. In an effort such as this we may secure some data which can be used later in the conquest of space or

for establishing systems in space. However, this seems to be of a one-shot matter and we should do it only under the condition that the costs are reasonable. That means that if we can use available hardware, with a cabin of some type for the man, we might try it. But to develop an entirely new device just for that purpose, and unquestionably spend millions of dollars, I think, then, this would be a waste of money.

Mr. O'BRIEN. I have one final question. I notice you are technical assistant to the president of the Bell Aircraft Corp. The president of the organization is a very close and old friend of mine. I was wondering, is industry, as represented by such corporations, ready to move step by step with this proposed agency when they outline their recommendations?

Dr. DORNBERGER. I think so.

Mr. O'BRIEN. Is it not a fact that in many phases of this space problem, industry is farther along than many of us realize?

Dr. DORNBERGER. With ideas, yes.

Mr. O'BRIEN. With ideas? I understand; yes. But you feel that industry can perform any function that this Agency will handle?

Dr. DORNBERGER. The whole question of space, in my opinion, is no longer a scientific question. We don't need any major scientific breakthrough. It is basically now an engineering problem, and I think our industry is capable and willing to make a realistic approach to the problem. Furthermore, I think we can do it.

Mr. O'BRIEN. Thank you very much, Doctor.

Dr. DORNBERGER. You are welcome.

Mr. O'BRIEN (presiding). Mr. Metcalf.

Mr. METCALF. You have based your whole statement upon the creation of a Secretary of Science. The chairman has discussed with you why it would not be feasible at this time to create a Secretary of Science. But we have this proposal to expand the NACA into a larger agency, the NASA. You say that this Agency should have no authority to decide about a project. Suppose we do not create a Secretary of Science. Who would have the authority to decide about a project?

Dr. DORNBERGER. The question of space is so important that all decisions should be made at the Presidential level. And this would apply whether we have a Secretary of Science or not.

Mr. METCALF. A director?

Dr. DORNBERGER. A director would be a good title. I am against committees and commissions and, if it isn't possible to set up a Secretary of Science parallel to the Secretary of Defense, with a Presidential space agency on top of this, then it may be necessary to give the Director of NASA authority to make decisions. But, as I have tried to explain, I am a little scared of what may happen in a couple of years when this Director might say: "I see no reason why there should be a manned reconnaissance satellite. As Director of NASA, I want top priority for a communications satellite which may reflect radar and radio signals. Furthermore, I want 3 television satellites established at an altitude of 23,000 miles so that we may service the entire globe and will be able to give the people of the entire world the TV programs of the United States."

This may be a little exaggerated example, but, if it should happen, we could not get research effort out of the NASA for military proj-

ects because the money available for the NASA would be used to do the jobs which NASA thinks should have top priority. Under such circumstances, I see the possibility of a collision of interests.

Mr. METCALF. You suggested that we are going to have to build in this step-by-step program, not too much to get machines or automatic devices into space, but to get men into space.

Dr. DORNBERGER. Yes.

Mr. METCALF. Have you ever made a proposal or a suggestion for getting man into space?

Dr. DORNBERGER. My proposal was the Dynasoar proposal, made in 1951 under a different name.

Mr. METCALF. Would you give us some background on that? To whom did you make that proposal?

Dr. DORNBERGER. That was made to the military, to the Air Force. It was finally accepted as a line proposal after 7 years. We could now fly with a man around the globe if we had started in 1951.

Mr. METCALF. Was NACA consulted, or the Director of the NACA consulted in that proposal?

Dr. DORNBERGER. NACA was working with us in doing some studies and research work.

Mr. METCALF. And concurred in this proposition?

Dr. DORNBERGER. They concurred in the proposition; yes.

Mr. METCALF. It was turned down by the military?

Dr. DORNBERGER. There wasn't money available.

Mr. O'BRIEN. Mr. Natcher.

Mr. NATCHER. Doctor, in your statement, you stress that research facilities should not be duplicated. I certainly agree with you, and I think every member on the committee agrees with that statement. You further state that:

> I think that the plan to expand the field of the National Advisory Committee for Aeronautics to take care of space research, also, is an excellent new idea. But this new National Aeronautics and Space Agency, as recommended by the President, should not try to develop its own space vehicles or to run projects. NASA should serve as a basic and applied research facility only, and should serve the scientists as well as the military.

Doctor, under the bill that we have before the committee, that we are studying now, on page 1 of this bill we have a declaration of policy. I want to read this to you, and see if you, in your mind, find any conflict with your statement and our declaration of policy.

That is on page 1, Doctor; Section 2: Declaration of Policy.

> The Congress hereby declares that the general welfare and security of the United States require that adequate provision be made for research into and the solution of problems of flight within and outside the earth's atmosphere, and that provision also be made for the development, testing, and operation for research purposes of aircraft, missiles, satellites, and other space vehicles, manned and unmanned, together with associated equipment and devices.

Doctor, is that vesting too much authority in the Space Agency?

Dr. DORNBERGER. No. I agree with it a hundred precent.

Mr. NATCHER. In other words, there if no conflict, then?

Dr. DORNBERGER. No. But I disagree with page 6, line 1.

Mr. NATCHER. Page 6, line 1.

Do. DORNBERGER (reading):

> Develop, test, launch, and operate aeronautical space vehicles.

Mr. NATCHER. In your opinion, Doctor, that should be stricken out?

Dr. DORNBERGER. Yes.

Mr. NATCHER. It should be stricken?

Dr. DORNBERGER. Yes.

Mr. NATCHER. In your opinion, you don't believe that the new agency should have that authority?

Dr. DORNBERGER. That is correct.

Mr. NATCHER. Now, I would like for you to explain to the committee a little more in detail as to why, Doctor.

Dr. DORNBERGER. A scientific research organization with the authority to develop its own projects will tend to back its own projects, exclusively. I saw the same kind of organizational setup in Germany fail dismally. There has to be unity between all interests, but a research organization is not the answer.

It is supposed to supply research, know-how, and facilities. Supposing the Secretary of Defense was concerned with getting a reconnaissance satellite up to an altitude of 100 miles, where he could get the type of information pertinent to the Military Establishment. Perhaps information even from behind the Iron Curtain. Conceivably, the NASA could say: "We are not interested in that. We are developing a communications satellite, and all our efforts and facilities are being devoted to that."

If we ever get put in this position, who is going to decide the relative importance of the projects? I say don't let a research agency do development work. They may help in the development done by others after a decision has been made at a top level. But the research agency should have no authority to make a decision.

Mr. NATCHER. Doctor, do you find any other provision of this bill that you would like to call the committee's attention to, that you disagree with, or do you have any advice——

The CHAIRMAN. Might I ask a question there?

Mr. NATCHER. Yes, Mr. Chairman.

The CHAIRMAN. I assume this is in connection with research and development that comes within the jurisdiction of this Agency. You would have some civilian agency have that power?

Dr. DORNBERGER. A civilian agency. I agree a hundred percent.

The CHAIRMAN. Who?

Dr. DORNBERGER. An expanded NASA should run the research facility.

The CHAIRMAN. What about "develop, test, launch, and operate?" You said you wouldn't put that there.

Dr. DORNBERGER. That is under my Secretary of Science.

The CHAIRMAN. Suppose we don't have a Secretary of Science?

Dr. DORNBERGER. That should be done by the National Science Foundation or National Academy of Science.

The CHAIRMAN. They have already testified that they would not.

Dr. DORNBERGER. They should, or another organization interested in space ships for scientific, commercial, or prestige reasons should handle the scientific phases.

The CHAIRMAN. There should be cooperation to some extent. Well, some civilian agency ought to have this power?

Dr. DORNBERGER. Yes. I agree.

The CHAIRMAN. All right.

Mr. NATCHER. Doctor, are there any other provisions in this bill that you would like to call to our attention?

Dr. DORNBERGER. I think when you strike No. 1 on page 6, then on page 7, line 7. If you do that, then you have to follow through.

Mr. NATCHER. Let's see, Doctor. On page 7, which line?

Dr. DORNBERGER. Paragraph (3), "To acquire, construct, improve, repair, operate, and maintain laboratories."

That is all right with me.

"Research and testing sites and facilities."

On testing sites, I would say "No;" "manned and unmanned aeronautical and space vehicles," that I would strike.

Mr. NATCHER. Doctor, assuming that this bill or a similar bill is enacted into legislation by the Congress of the United States, the NASA will take over the duties, powers, and functions of the NACA.

The NACA has about $500 million worth of property and 7,600 employees.

The provision there is a matter of taking over of the present existing agency. Do you object to that?

Dr. DORNBERGER. No; to the contrary. But the NACA up to now has not developed one single airplane. The airplanes were developed by the civilian organizations, by the commercial organizations, or by the military.

The NACA just tested some of them, did research work with some of them.

Mr. NATCHER. Thank you very much, Doctor.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. Doctor, I hesitate to take the time to go back over this. I would like to clarify, in my own mind, a little bit further, just who will have the authority to make the final decision. On the bottom of page 11, of course, as has already been called to your attention by the gentleman from Montana, you state that it should have no authority to decide about a project. You are referring to the NASA?

Dr. DORNBERGER. Yes.

Mr. SISK. On the top of page 12, you go ahead and state in the first paragraph that:

> Direct and close coperation between the two main scientific and military agencies and the expanded NASA is mandatory.

I think certainly we can all agree on that.

> But any difference of opinion between these agencies which are to lead the United States into the space age should be straightened out by the space agency on the Presidential level.

How you would differentiate between that and what you said at the bottom of page 11 is what I am talking about.

Dr. DORNBERGER. In order to clarify my opinion of the importance of decisions on space, I mentioned first that I thought of a kind of vice president of space, or space agency reporting directly to the President. This would be a court of last appeal on space questions. And when it comes to decisionmaking or execution, then the President or the agency at the Presidential level, should have the final word. There must be someone or some agency not directly related to the military, scientific, commercial, or research organizations who would make final decisions.

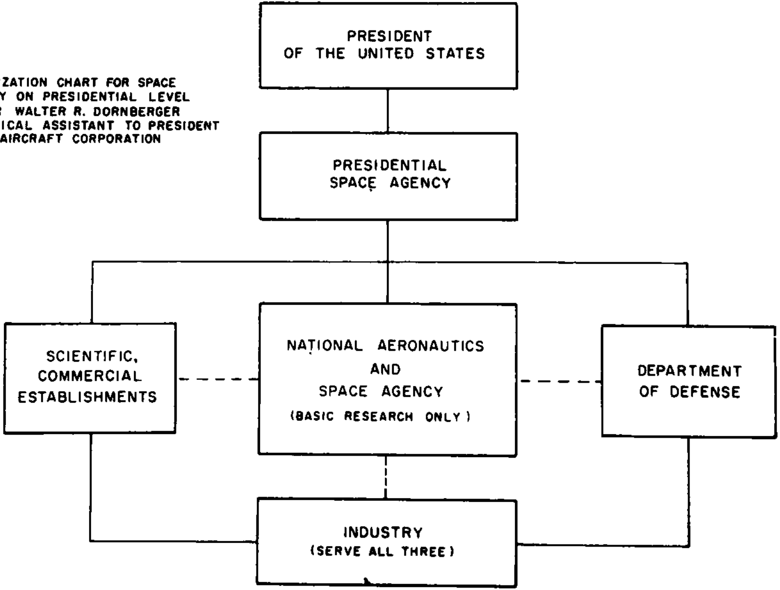
Mr. SISK. I understood your desire, of course, for either a vice president in charge of science or a secretary of science. In fact, frankly, Doctor, I have rather leaned in that direction myself at times.

But the only question, and I understood your recommendation is when you refer to the space agency on the Presidential level, I just wanted to get clear in my mind actually to whom you were referring in that instance.

Dr. DORNBERGER. May I draw you a sketch of my conception of a space organization.

(The chart referred to above follows:)

ORGANIZATION CHART FOR SPACE
AGENCY ON PRESIDENTIAL LEVEL
BY DR WALTER R. DORNBERGER
TECHNICAL ASSISTANT TO PRESIDENT
BELL AIRCRAFT CORPORATION



Mr. SISK. Thank you, Doctor. I think this certainly clarifies in my own mind your thinking. Then, as to how these various agencies will fit together. That was the thing that, frankly, I was having a little difficulty with. I think this certainly does clarify it. I thank you very much for it.

I might say, Mr. Chairman, that we might get the Doctor to place this in the record, along with his remarks, which I understand we will have an opportunity to expand and correct.

You have the right to edit your remarks, to go over them, in other words, and add or clarify them in any way you want to, Doctor.

The CHAIRMAN. Mr. McDonough.

Mr. McDONOUGH. Dr. Dornberger, you have had a vast amount of experience in this rocket propulsion. Your advice and counsel here are very welcome and very much appreciated.

You evidently believe in a straight line of command, with authority at the top, and with duplication held to a minimum, all of which is good management. We hope we can find a way to do that.

In your position in the Peenemunde project, do I understand from your statement here that you reported direct to the head of the German Reich?

Dr. DORNBERGER. Yes.

Mr. McDONOUGH. That was to Hitler?

Dr. DORNBERGER. Yes.

Mr. McDONOUGH. You had no limitation on the funds, you were given a free hand to operate and so forth?

Dr. DORNBERGER. Yes. I was further told: "If you succeed, we will place the highest decoration we have in Germany around your neck. If you don't succeed, you will have a noose around your neck."

Mr. McDONOUGH. What background did you have for such an appointment previous to this?

Dr. DORNBERGER. I was an active officer of the German Army, but I went to college as a captain in the German Army and studied for 5 or 6 years and got my degrees in mechanical engineering and my doctor's degree in engineering. Then I came back on the Board of Ordnance and I was asked to take over the rocket development, and I had to do it.

Mr. McDONOUGH. In other words, your mechanical——

The CHAIRMAN. You said you had to do it?

Dr. DORNBERGER. I had to do it; yes.

Mr. McDONOUGH. In other words, your education in mechanical engineering was a great asset?

Dr. DORNBERGER. Yes.

Mr. McDONOUGH. At that time you had nothing on astrology, meteorology, or astronautics?

Dr. DORNBERGER. No. As a military man, you have quite some experience in treating people, and you succeed as an officer only if you can put the right men on the right spot. It is the same in the industry. I think my studies at the technical university in Berlin helped me to put the right engineers on the right spot, and the right scientist on the right spot.

Mr. McDONOUGH. You were very fortunate. How many failures did you have in the V-2 rocket before you had a successful rocket?

Dr. DORNBERGER. We had two failures before we had the first successful flight, and then we had 36 before the next successful flight.

Mr. McDONOUGH. Two before the first and thirty-six before the second?

Dr. DORNBERGER. Yes.

Mr. McDONOUGH. Do you mean that after the 36th failure you were able to hit the target pretty accurately?

Dr. DORNBERGER. No; not accurately. At that time, the guided system did not work so good. After we started firing in the first year, we had an overall reliability of approximately 30 to 40 percent. When we went into operation, we had overall reliability of approximately 75 percent. At the end of the war, we had an overall reliability of the V–2 of 78 percent.

Mr. McDONOUGH. You studied only the project of propelling a rocket into space with a warhead on it to hit at a designated target?

Dr. DORNBERGER. Yes.

Mr. McDONOUGH. At what elevation did you shoot the highest rocket?

Dr. DORNBERGER. Usually we fired with 45° elevation at the burning cutoff point. With a shot fired vertically, we obtained an altitude of 125 miles.

Mr. McDONOUGH. 125 miles?

Dr. DORNBERGER. Yes.

Mr. McDONOUGH. Of course, you understand that your recommendation for a vice president of space would require a constitutional amendment in this country?

Dr. DORNBERGER. I don't think so. You have a Vice President. Why don't you give him this additional work to do?

Mr. McDONOUGH. Put him up in space, do you mean?

Dr. DORNBERGER. No.

Mr. McDONOUGH. He is covering a lot of territory right now on earth as it is. I don't know whether we can get him off the ground or not.

I noticed that in your statement you said whatever followed was over a period of some 20 years, and that you believed that the first objective was to develop the basic research on space technology and apply it as we go along.

Dr. DORNBERGER. Yes.

Mr. McDONOUGH. And that we should not do anything spectacular because, perhaps, on the other hand, the Russian people may do such a thing for propaganda purposes and we should not be disturbed about a thing like that.

Dr. DORNBERGER. We should not be. But, on the other hand, if, for prestige purposes, we need such a thing, and if we can achieve it by using available hardware, I would say yes, we should do it.

Mr. McDONOUGH. When you say 20 years, what, in your opinion, with a concentrated program, with the elimination of as much duplication as possible, in what period of time from now on could we put a man in space in a manned space vehicle to go into cislunar space and return to earth?

Mr. DORNBERGER. I think that a man can fly around the globe within 1½ years, but we are not quite 100 percent sure if we can get him back where we want him. But to get a man up in space, or even a

crew, to fly around the globe up to 7 times and land at a predetermined landing strip is the real problem. This will take approximately 4 to 5 years.

Mr. McDONOUGH. Do you think that we are making as much progress as we can make with the scientific manpower we have in this country and the industrial know-how?

Dr. DORNBERGER. I have no doubt that the scientific manpower needed is available. The problem is only that we lose too much time before we start something.

Mr. McDONOUGH. How long do you think it will take us to develop a half million pound thrust engine?

Dr. DORNBERGER. It will take 2½ years, to get it reliable.

Mr. McDONOUGH. We are working in that direction now.

Dr. DORNBERGER. Yes; but that is not enough.

Mr. McDONOUGH. No?

Dr. DORNBERGER. We need much more thrust.

Mr. McDONOUGH. Will it take 2½ more years to develop a million pounds thrust?

Dr. DORNBERGER. It will take 3 years or 3½ years to develop a 1 million-pound-thrust engine. But I only hope that the 1 million-pound-thrust engine will not be based on conventional propellents, but that we will immediately go to high energy propellents.

Mr. McDONOUGH. As I understand your recommendation here, you believe that this Agency should develop basic research, and approach up to the point of experimentation, and from there on cease to operate?

Dr. DORNBERGER. Yes.

Mr. McDONOUGH. It should go over to private industry from that point?

Dr. DORNBERGER. Yes.

Mr. McDONOUGH. They should write specifics, outline procedures, and inform industry what they want after they have thoroughly tested it and found that it is practical?

Dr. DORNBERGER. Yes.

Mr. McDONOUGH. That is a very good thought. Thank you.

The CHAIRMAN. Mr. Fulton?

Mr. FULTON. I will yield to Mr. Ford, who has been continually last.

Mr. FORD. The main thing I get from your testimony, Doctor, is that you believe there should be a strong director who will have very few restrictions on the administration of the program. That was your experience during World War II and that is what you think would be most effective for this kind of an organization. As I read the bill which has been submitted, in effect that is what is aimed at, although there is an advisory board composed of 17 members.

You do believe that in this kind of an agency, even though it does not coincide with the area that you are proposing generally, that there should be a director, such as is recommended here?

Dr. DORNBERGER. There should be a director. But the makeup of the man is the most important.

Mr. FORD. How do you feel about a board of directors as envisioned here?

25973—58——70

Dr. DORNBERGER. I think there should be a director. I think also there could be a board numbering 17 members as outlined in the bill. The board should act only in an advisory capacity. The authority would be selective, to make final decisions should be vested only in the director.

Mr. FORD. You prefer the director type in contrast to the commission type, where you have 3 to 5 to 7 members?

Dr. DORNBERGER. I certainly do.

Mr. FORD. Thank you very much.

Mr. FULTON. We are glad to have you here, and we think you have done fine work. I like your approach, going step by step with about 10 or 12 steps being proceeded upon at the same time, some of short duration and some of longer time. That is what you have in mind, is it not?

Mr. FORD. Yes.

Mr. FULTON. There are various projects, each of which would begin now, but which might have a longer time of fruition.

I was amused at the exchange between you and my good friend from California on astrology. Astrology, of course, is the science of the stars as to their effect on human beings, when they are born, when to plant, and when to do other things, while astronomy, of course, is more of the science of the stars.

I don't think either of you meant you were proceeding on any basis of astrology in the space field; did you?

Dr. DORNBERGER. No; I am not. I am a little bit more realistic. I don't know what will happen in space or for what we will use space. I am sure nobody knows. But I think we should go out and find out.

Mr. FULTON. There is this possibility, that we can use space to benefit mankind. For example, we have present circulatory diseases, diseases caused by air pressure, even heart diseases.

The hospitals of the future might be in outer space on things like heart diseases.

Dr. DORNBERGER. I agree with that. We may find things in space that are absolutely of no use to us. There may be other things which will be greatly to our advantage. But before we try to determine theoretically what exactly exists in space, I think we first should go up into space. We may find there are hazards whose existence we are unaware of and there may be other things which will prevent us from doing many of the things we believe now we can do.

Mr. FULTON. And we may find that the rate of cell development is controlled in some degree by the position you are in in outer space.

We may have various locations for various diseases, or for growth, or for young people or old people.

Dr. DORNBERGER. I agree.

Mr. FULTON. We might have an old person's home, then, in outer space.

I agree with you that nuclear propellents are the prime point to be considered on our development of space vehicles and space missiles. I think that is an excellent point, that you say it should come first as a prime factor.

You would stress that?

Dr. DORNBERGER. Yes; it should come first. As I indicated in my remarks, Germany had at least the same basic ideas about space as we have in this country but Germany at that time didn't have the tools until they developed a highly efficient powerplant and followed this with the development of the required guidance system. But even the tools they had were not sufficient to allow them to go into space. Despite the fact that we don't have in this country all the tools and all the knowledge, there is still considerable talk about space vehicles and how soon we will go into space. To expedite our entry into space, I think we should develop the tools and, of course, I mean propellents and guidance and so forth now, without even fully knowing for what purposes we would use them later.

Mr. FULTON. We have a man named Admiral Rickover who has adapted nuclear-power propulsion to submarines which operate in the medium of water.

It is fairly well along on development now, so that it is merely the flattening out of the curve of progress. Why not take a man like Admiral Rickover over into the Space Agency and say, "Look, get on the nuclear propellents in outer space."

He did a pretty good job on the submarines. Would you recommend such a thing immediately?

Dr. DORNBERGER. The type of directorship such as held by Admiral Rickover is what I would propose.

Mr. FULTON. But we would need the kind of a man who has perseverance to put a program over for outer space; would we not?

Dr. DORNBERGER. Yes.

Mr. FULTON. May I finish with this? I have often wondered, coming from a coal-mine country, when there were mines around Peenemunde, why didn't you put the Peenemunde installation in the coal mine.

Why was it so unprotected on the surface? If it had been around Pittsburgh, we would certainly have had it in a coal mine.

Dr. DORNBERGER. Well, that is a good question. However, you probably know the Secretary of the Air Force we had at that time. He made a statement that his name would be Meyer if there ever was an enemy airplane over the area. Of course, we began calling him Meyer in 1941. I think Peenemunde itself, along with the atom bomb, was one of the best kept secrets of the war. We started at Peenemunde in 1937 and even by 1945 American-British intelligence still didn't know the names of the leaders at Peenemunde.

Mr. FULTON. The Russians weren't able to get anything about Peenemunde, were they, but they were able to get some of our atomic secrets 6 months after they were told to get them? The Russians never got anything from Peenemunde, did they?

Dr. DORNBERGER. No.

Mr. FULTON. Thank you. You have been a good witness.

The CHAIRMAN. Mr. Ford.

Mr. FORD. Doctor, what is the definition of cislunar?

Dr. DORNBERGER. Cislunar space is the space between the moon and the globe, a distance roughly of 286,000 miles.

Mr. FORD. Anything from here to the moon is cislunar?

Dr. DORNBERGER. Yes; and beyond the moon is translunar.

Mr. FORD. Translunar?

Dr. DORNBERGER. Yes.

Mr. FORD. Thank you very much.

The CHAIRMAN. Mr. Feldman?

Mr. FELDMAN. Doctor, can you contrast the power to make decisions that you enjoyed in Germany and which you have described already with what you found in the military organization of this country?

Dr. DORNBERGER. Here in this country when the missile and rocket programs began to develop, too many offices, departments, and divisions, to say nothing of committees, sought to have voices in these matters. Already it is evident the same situation is developing in the field of space.

I think one office is sufficient. One person in one office in the Air Force, in the Army, and in the Navy should make preliminary and final decisions and should be able to handle all problems, big or small.

Now there are 20 or 30 offices in different locations in the country and when you propose a project, generally you have to run through all 20 or 30 offices. This can take a proposal 2 years to complete and then when you are through, you start all over again because officers in charge of the various military departments usually rotate every 2 years. This can be really frustrating.

Mr. FELDMAN. You stated also that you presented a plan for a space ship in 1951 and it was not started until 1957 or 1958—7 years later. What took place in between the time of your original proposal and 1958?

Dr. DORNBERGER. I can tell you what happened. I made 678 presentations about that project to all the different military offices involved in all parts of the country.

Mr. SISK. Will the gentleman yield? Did I understand that he made 678 presentations of this particular project?

Dr. DORNBERGER. Yes.

Mr. SISK. Over a period of how long, Doctor?

Dr. DORNBERGER. Seven years.

Mr. SISK. Thank you.

Mr. FULTON. During what period?

Mr. FELDMAN. 1951 to 1958.

You spoke of the fact that it would take 3½ years to develop a space ship which would circle the earth several times and then arrive at a predetermined spot. Did that contemplate a program which might be delayed through lag or the kind of barriers that you encountered previously?

Dr. DORNBERGER. No. I think the main reason is, you know, the shirt is always a little bit closer to the body than the jacket. At that time we were at the point when we had to fight the Korean war with the weapons we had, and the feeling was that we had to mass-produce these weapons, which were still superior to the Russian weapons. At that time money was spent in that kind of weapons systems and there was not enough money to start an expensive new project, such as putting a man in space. I can understand the attitude of the military. But with a little bit bolder approach, we would have been much farther now.

Mr. FELDMAN. I think you misunderstood my question. My question is this—I believe in response to a previous question, you were

asked how long it would take to develop a space ship now. You said to develop the kind of a space ship which would circle the earth several times and then land at a predetermined spot would take 3½ years.

Dr. DORNBERGER. Let me restate it. First, to send a man around the globe, without knowing exactly where he would come down, would take 1½ years. But to send a ship into space with a crew of two, which would circle the globe perhaps up to seven times and then come back to a predetermined landing strip so that the ship could be reused, will take 3½ to 5 years.

Mr. FELDMAN. I misunderstood you. But using that as a hypothesis to this question, does that contemplate a green light to go ahead and start on such a project at that time, or is such a project underway at this time?

Dr. DORNBERGER. We are waiting for the green light now. As far as I know, the decision will be made in the next couple of days.

Mr. FELDMAN. You feel confident that you can accomplish what you said you could accomplish?

Dr. DORNBERGER. I feel confident that such a project could be accomplished.

Mr. FELDMAN. How seriously do you regard this whole problem of conquering space?

Dr. DORNBERGER. I think it is very important.

Mr. FELDMAN. Would you call it a life and death struggle?

Dr. DORNBERGER. It is a life and death struggle of our Nation.

Mr. FELDMAN. Why?

Dr. DORNBERGER. We are confronted with only a single competitor and that is Russia. Russia is able and has the money, the raw materials and the intelligence to conquer space. We learned from sputnik what it means under the present international political situation to achieve something in this field first. We have to do it or suffer the loss of our prestige among the free nations.

Mr. FELDMAN. Is that the only reason?

Dr. DORNBERGER. No, there are many reasons. The development of high-thrust rocket propulsion will give us the means and the tools to expand our field of travel tremendously in a vertical direction. Space travel promises tremendous new knowledge, the understanding and use of which we may not recognize now but in the next 10 or 15 years space will be an area of vast importance for our country both scientifically and militarily.

Mr. FELDMAN. I have no further questions.

Mr. MCDONOUGH. Mr. Chairman?

The CHAIRMAN. Mr. McDonough?

Mr. MCDONOUGH. In your early developments in Peenemunde did you use the research and experiments of Dr. Goddard to any extent?

Dr. DORNBERGER. No, we did not. Dr. Goddard was almost unknown to us. At least 98 percent of Dr. Goddard's patents were classified. We had no access to them. We had some information about Dr. Goddard's work by the American Rocket Society Journals, and that was all we got. But at that time, when we got knowledge, and we learned about Professor Goddard's achievements, we were already ahead and far ahead of him. The development in Germany was parallel to Dr. Goddard's and not one after the other.

Mr. McDONOUGH. But you worked on the same basis, the same basic principles?

Dr. DORNBERGER. Yes. I am convinced that any nation in the world, with the same scientific background and the same scientific and engineering capabilities and capacities, when tackling the same problems, would finally come out with the same solution.

Mr. McDONOUGH. Why, in your opinion, hasn't Russia shot another satellite up since the last one?

They have not shot another one since the last one. They have only put up two.

Dr. DORNBERGER. I am not quite sure that they didn't try.

Mr. McDONOUGH. You think they did try?

Dr. DORNBERGER. Yes.

Mr. McDONOUGH. You have no knowledge of that?

Dr. DORNBERGER. I have no knowledge of it.

The CHAIRMAN. How far ahead of us are the Soviets in the field of intercontinental ballistic missiles? Have you an opinion?

Dr. DORNBERGER. We got information that the Russians shot one ballistic missile over a range of 5,000 or 6,000 miles. I don't know of any ICBM we have fired over that range yet.

The CHAIRMAN. Thank you very much, Doctor. We appreciate your appearance. We are very glad to have you before us. I, as chairman of the committee, and on behalf of the other members of the committee, wish to express our thanks to you very much.

Dr. DORNBERGER. Thank you.

The CHAIRMAN. The next witness is the Honorable Donald A. Quarles, Deputy Secretary of Defense.

STATEMENT OF HON. DONALD A. QUARLES,[30] DEPUTY SECRETARY OF DEFENSE

The CHAIRMAN. We are very glad to have you with us, Mr. Secretary. Have you a prepared statement?

Mr. QUARLES. I have not, Mr. Chairman. I have come here with the thought of answering any questions you might have in response to your request about our comments on the legislation. I thought I would, however, not do that in a comprehensive way at this time, but merely consider with you any questions that the committee might have.

The CHAIRMAN. What is your opinion as between a director or an administrator, whichever you want to call it, and a commission form of agency?

Mr. QUARLES. Generally speaking, I think an agency with a single effective head is a preferable organization. Of course, that is not to say that the effective head of the agency might not have firm policy

[30] Quarles, Donald A(ubrey), Deputy Secretary of Defense: b. Van Buren, Ark., July 30, 1894; s. Robert W and Minnie (Hynes) Q.; B. A. Yale, 1916; grad. study Columbia, 1920–24, m. Rosina Cotton, Oct. 27, 1939; children (by former marriage)—Carolyn Anne, Donald Aubrey, Elizabeth Whittemore. Engr. Bell Telephone Labs. (formerly engring. dept. Western Electric Co.), since 1919, v. p. since 1948; v. p. Western Electric Co., pres. Sandia Corp., since 1952; asst. secretary of defense (research and development), Washington, 1953–55, secretary of the Air Force, 1955——. Former mayor of the city of Englewood, N. J. Served as capt., F. A., U. S. Army, 1917–19. Fellow Am. Inst. E. E. (pres. 1952–53), Am Phys. Soc, Am. Inst. Radio Engrs.; mem. A. A. A. S., Yale Engring. Soc., Telephone Pioneers Am., Sigma Xi, Phi Beta Kappa. Republican. Clubs: Englewood; Knickerbocker Country (Tenafly, N. J.); Cosmos (Washington); Engineers (N. Y. C.). Address: 3041 Porter St, Washington 8. Office: The Pentagon, Washington.

guidance by what would be the equivalent of a board of directors or a board of trustees or something of that kind.

But I think from the point of view of directing the agency, it would be more effective to have a single head rather than to have a commission as head of the agency.

The CHAIRMAN. You are confining your reply to this particular agency?

Mr. QUARLES. To this particular agency; yes, sir.

The CHAIRMAN. You do not want to go beyond that agency.

Mr. QUARLES. So that I will not be misunderstood, there are some commission forms of agencies which are extremely effective. But for this purpose, I would think a single director or a single head of the agency would be sufficient.

The CHAIRMAN. Do you think he should be on a high level?

Mr. QUARLES. I would think so; yes.

The CHAIRMAN. On the level of the National Security Council, for example?

Mr. QUARLES. Not necessarily on that level.

The CHAIRMAN. You would not exclude it, would you?

Mr. QUARLES. I would not exclude it, but I think that the level that we are talking about is not necessarily a National Security Council membership.

The CHAIRMAN. Do you think the Administrator should be a member of the National Security Council?

Mr. QUARLES. I would not see a reason for that; no, sir.

The CHAIRMAN. I will ask some questions later. I will ask the members of the committee if they have any questions.

Before doing that, however, you remember the Riehlman subcommittee, do you not?

Mr. QUARLES. Yes, sir; I do.

The CHAIRMAN. Has that had any effect? I thought we did a pretty good job. I sat in on all those hearings.

Mr. QUARLES. I thought the committee did an excellent job, Mr. McCormack, of delving into that problem. I would say it has had an effect. Like many of these things, one has to look carefully to see just what changes have taken place over a period of time. But I believe there very definitely has been an evolution, and in the direction your subcommittee was seeking. I hope you will agree with me.

The CHAIRMAN. Since sputnik I have seen some evidence.

Mr. O'Brien.

Mr. O'BRIEN. Mr. Secretary, you say you do not believe necessarily the Director of this new Agency should be a member of the National Security Council. May I ask why not?

Mr. QUARLES. Well, I think, of course, that the President might see fit to call on him for advice when matters pertinent to his work were involved. But the great bulk of the National Security Council matters would not be of interest to him, and I would say it would be better to have him called in as the occasional adviser rather than having him sit as a regular member, in my understanding of the character of his work.

Mr. O'BRIEN. Do you believe, Mr. Secretary, from your reading of the President's proposal and the several other proposals, that enough authority is granted the Director of this new Agency to do the job which should be done, or do you think that in writing or rewriting this

legislation, we should spell out more authority than presently provided?

Mr. QUARLES. My feeling was that the legislation as it stands does establish very substantial authority in this Director.

I am not sure that I have analyzed that as closely as one should. But certainly my impression is that the authority as it stands is appropriate and adequate for his purpose.

In the final analysis, of course, his authority is really his appropriation, and this is something that the legislation is, of course, silent on, other than authorizing the appropriation.

I would say that given the appropriations to do the job expected, that he has the authority to carry out the job.

Mr. O'BRIEN. Thank you. That is all, Mr. Chairman.

The CHAIRMAN. I think it is a good basis for consideration. I agree with you, Mr. Secretary. Otherwise, when introducing it, I would have stated "by request," but I did not do that. But as a basis of consideration, I think it was a job well done.

Mr. Metcalf.

Mr. METCALF. I have no questions.

The CHAIRMAN. Mr. Natcher?

Mr. NATCHER. Mr. Secretary, the bill before the committee providing for the Space Board provides that the Board shall not exceed 17 members and at least 1 of the members shall be from the Department of Defense. You are acquainted with that provision?

Mr. QUARLES. Yes; I am, Mr. Natcher.

Mr. NATCHER. Mr. Secretary, in your opinion, should each branch of the service be represented on this Board? Should there be more than one member from the Department of Defense?

Mr. QUARLES. As a general proposition, I would say that of the 17 members it would be appropriate not only to have 1 from Defense, but to have 1 from probably each of the 3 military departments, certainly 1 or 2 additional members from the Defense Department. I believe it is provided that not more than 8, is it not, shall be from Government offices and, of course, this would permit the possibility of 2 or 3 being from the Defense Establishment. Whether it would be wise and appropriate to specify that more than one be from the Defense Establishment I think is debatable. As a matter of fact, I am quite satisfied with the present provisions of the bill in that respect, assuming that appropriate people would be appointed when the time came.

Mr. NATCHER. Thank you, Mr. Secretary.

The CHAIRMAN. As a matter of fact, instead of spelling it out in the bill, you would prefer that at least one should be appointed from the Defense Department? That would allow more and that then would rest with the President in conjunction with the Secretary of Defense and the head of this Agency.

Mr. QUARLES. I think I remember now it does say at least one.

The CHAIRMAN. At least one?

Mr. QUARLES. Yes.

The CHAIRMAN. And then if we put one from each department, in miniature we are repeating the reorganization fight, are we not?

Mr. QUARLES. I think, perhaps, if you required that there be one from each department in legislation you might be stepping on organization's toes there, but I have not thought of it in that sense.

The CHAIRMAN. I said in miniature.

Mr. QUARLES. Yes; anyway, I would like to leave it that the present provision of the draft bill in that respect seems appropriate to me.

The CHAIRMAN. Mr. Sisk?

Mr. SISK. Mr. Secretary, how do you visualize or anticipate the relationship between ARPA and the new Agency would be carried on? Do you propose, as I understand, that ARPA will continue to operate as part of the Department of Defense? Is that correct?

Mr. QUARLES. That is correct, Mr. Sisk, and we believe that there will always be advanced research projects in this particular space area, as well as perhaps in other areas.

There will be projects appropriate for military control and conduct, and these projects we would expect to continue to be carried on in the Advanced Research Projects Agency of Defense.

Just where that line will be drawn, and how the collaboration between Defense and the new NASA will be worked out, I think is the key question before us at this time.

Mr. SISK. That leads to my next question: Assuming that there arose a controversy as to a given project, or a given attempt to explore space, as to whether it has military significance or it should be exclusively under a military agency, who, in your opinion, should make the final decision? Should this Agency we propose to set up have authority vested in a Director to overrule ARPA, for example, and make that decision?

Mr. QUARLES. I would think that would not be appropriate, Mr. Sisk. I would think in final analysis that decision should be vested in the President and that the legislation should not attempt to draw the line too firmly and definitely because I believe administrative latitude will be valuable here in working out this relationship.

For example, I can well imagine that the line that one would draw initially when the new Agency is getting into this field might be somewhat different than the line one would draw after they had been in the work for several years and had become established in it.

In any event, I, myself, would like very much to see a continuation of the relationship—essentially the relationship—that has existed in the past in the aeronautics field between the Department of Defense and its military services and the National Advisory Committee for Aeronautics.

I do not mean to imply, by that, that in the space field the new NASA should not go farther and have its own projects—I think it should—but I think the main point here is to establish a collaboration between the two agencies, each drawing on the capabilities of the other, and each relying in confidence on the other in the way we have had it in the relationship between the Defense Department and its agencies, on the one hand, and the Advisory Committee for Aeronautics, on the other.

Mr. SISK I am inclined to agree with you; that is an idealistic setup. However, as a realistic setup, if there is an urgency, which we are told exists and which many of us believe exists, as controversies and disagreements arise, I understand you do say the President shall make the decision.

Now, I would assume you propose he would rely on Dr. Killian or his other scientific advisers. I am wondering if there would not be

rather lengthy delays because of the necessity of this third party, whether it be the scientific adviser to the President or another, making the decision. Apparently, you do not have that fear. Is that correct?

Mr. QUARLES. I do not have that fear, Mr. Sisk, for this reason: That I think, initially, there will be a determination by the President and, of course, when I say the President, I mean on his behalf and by him if he needs to make the determination, personally.

I think there will be a determination as between the defense agencies, let us say ARPA, and NASA, and that will establish a dividing line between them.

In line with that determination, they will each proceed on that program or on joint programs, as may be determined, and as new programs come along they will either fall into that pattern or, I think, can be promptly resolved.

I do not see that this would be a delay. In fact, on the contrary, it is the only orderly way you could carry on, and you might very well encounter delays if you did not have some orderly process like that for resolving the basic questions.

Mr. SISK. Do you think that should be spelled out in this legislation, then as to who might be called upon to settle these differences of opinion?

Mr. QUARLES. I think it is implicit in the legislation as it stands. It seems to me that it is quite clear that both the Defense Department and the new Agency are responsive to the President and, therefore, as in the case of all other executive-branch agencies, they would look to him for adjudication of any differences between them.

Mr. SISK. I believe that is all. Thank you, Mr. Chairman.

The CHAIRMAN. Mr. McDonough.

Mr. McDONOUGH. Mr. Secretary, do you think our immediate emphasis on space exploration should be for military purposes, or for peacetime purposes for civilian benefits?

Mr. QUARLES. I would like to say I think it should be both. I think one could not say it should be civilian to the exclusion of the military, because I think the national interest requires priority attention to the military and defense aspects of this program.

On the other hand, if one concentrated exclusively on these near-term military aspects and did not move vigorously into the longer range exploratory field to develop the science of this situation, then we might be grossly shortsighted and find ourselves outclassed as we get down the road further. I think it has to be both things, and both things in parallel, and both things with priority.

Mr. McDONOUGH. Under the many pertinent provisions in the bill before us is item 5 on page 2, which states:

> The making available to agencies directly concerned with national defense of discoveries that have military value or significance.

The National Space Agency that the bill would create, with at least 1 from the Defense Department in a board of 17, would, naturally, emphasize by its personnel and the limited number from the Defense Department more civilian investigation than the military. The bill, itself, states that the things discovered having a military purpose should be referred to the Defense Department.

The bill also provides that we should seek to cooperate with foreign nations and even enter into international agreements to bring about

peaceful settlement of how space should be used. What is your opinion about that?

Mr. QUARLES. I should not think it would be a function of this Agency to enter into international arrangements about the use of space.

Mr. McDONOUGH. I am wrong; I mean cooperate.

Mr. QUARLES. Yes, sir. Well, I would say that, with proper guidance as to the areas in which such cooperation should take place, it would be desirable and serve the national interest for this Agency to cooperate with other national bodies, or in international bodies, but that would have to be carefully considered in relation to those things that should be secured in the national interest.

I think it undoubtedly would be, but there certainly would be areas of general science in which it would be appropriate for this Agency to cooperate with the agencies of other nations just as we have in the International Geophysical Year.

Mr. McDONOUGH. Now, we are engaged in an International Geophysical Year at the present time. The purpose, of course, is cooperation and coordination between various nations on scientific exploration of space.

Suppose the International Geophysical Year terminates, and Russia then indicates that any attempt to use satellites for reconnaissance, surveillance, or investigation of outer space is an overt act. What position does that put us in, as a nation, in our military defense?

Mr. QUARLES. It is a little hard to see how they could take that position after their own experiments in this field, in which they seem to assume that there was no such question of international relationships.

Mr. McDONOUGH. Well, that was during the Geophysical Year. They did not shoot a satellite before. Neither did we. They did it during the Geophysical Year.

Mr. QUARLES. That is very true, but I think, from the point of view of international law and the rights of other nations, these were not changed by the International Geophysical Year, and anything that is proper to do in that year would be proper to do in the following year, from the point of view of rights of nations.

We ceded them no rights, and they ceded us none, although our scientists did enter into cooperation in this Geophysical Year program.

My only point is that I would not expect that they could take the position that an orbiting satellite would be an infringement on their national rights, but, if they do so, that would, of course, have to be a matter for our State Department to deal with and not for this Agency to deal with.

Mr. McDONOUGH. Suppose they release a satellite that we know is capable of reconnoitering the United States, and we have no such satellite in orbit. Would that be considered an invasion of our security?

Mr. QUARLES. I am not enough of a lawyer, Mr. McDonough, to answer that question. I can only express the Defense Department's view of it, that, if they did place in orbit a satellite that had such reconnaissance possibilities, we would consider that it was inoffensive in the sense that it was in outer space where it could do us no harm and we could not object to it.

Mr. McDonough. Of course, we do not know whether Sputnik II had such capabilities, because we could not decode the messages from it, could we?

Mr. Quarles. I think it is true that we do not know, definitely, what information either sputnik actually obtained and returned. There were intimations that information of that kind might be gathered. Whether such information was or was not gathered, I think, we do not know.

Mr. McDonough. Were they able to decode the messages from our satellites?

Mr. Quarles. The information gathered and returned by our satellites was in accordance with the international agreements and codes and freely available to all nations participating.

Mr. McDonough. That is all, Mr. Chairman.

The Chairman. Mr. Fulton.

Mr. Fulton. I yield to Mr. Keating at the present time, Mr. Chairman.

Mr. Keating. Mr. Secretary, this bill says that not more than one shall be from the Defense Department. There have been some recommendations here that we incorporate language saying not more than one each from the Army, Navy, or Air Force.

Would you be opposed to language of that kind?

Mr. Quarles. I would not oppose it, Mr. Keating, but I do not think I would advocate it on the theory that if the representatives of Army, Navy, and Air Force appeared to be the best-qualified members for appointment to this 17-man Board, we would certainly recommend their appointment, and I have every reason to believe that the recommendations would be given sympathetic consideration.

So I do not see the necessity for incorporating such language into the act.

Mr. Keating. Would not language of that kind be contrary to the spirit of the Defense Reorganization Act which has just been presented to Congress?

Mr. Quarles. One could say that it is and for that reason there might be some advantage in omitting it.

Mr. Keating. In other words, if there were to be 4 from the Defense Establishment, not more than 4, or not more than 3, or any other number, do you not feel they should be designated by the Secretary of Defense?

Mr. Quarles. I think that would be a good approach to the matter at this time; yes, sir.

Mr. Keating. There has been discussion here about spelling out the method by which liaison shall be maintained between the armed services and a civilian agency. Do you favor simply setting up the liaison requirement in general, or spelling out the details in legislation?

Mr. Quarles. I favor legislation which establishes the agency and defines its purposes and functions broadly and does not attempt too rigidly to establish a line between this Agency and the military agencies, for two reasons:

I think that this will be an evolving relationship as time goes on. I think that initially there might be one division between them and as the new Agency builds up there might very well be a somewhat different relationship.

Generally speaking, I think it would serve the national welfare best to have the flexibility which would enable the two agencies under the direction of the President to adjust this dividing line between them as time goes on and according to circumstances.

Mr. KEATING. Do you not think that if we were going to set up definite guidelines as to how that liaison should be accomplished, we could do it better after the Agency had been in operation for 2 years than at this time?

Mr. QUARLES. I think that is true; yes, sir. I would like to recommend that the legislation not attempt to establish prohibitions that, let us say, Defense shall not do certain kinds of things and that the Agency shall not do certain kinds of things.

I do not believe that is necessary. Both agencies should be working for the national welfare in their respective fields and there should be a possibility of adjustment between them under the direction of the President, I should say.

Mr. KEATING. Now, you gave an answer to Mr. McDonough on one question that rather surprised me, if I understood you correctly. He asked you about the Russians sending satellites with reconnaissance capabilities over this country.

I understood you to say that no harm could come from it, so we could not object.

Now, my understanding is that from 500 miles up you can take a picture of an object, or you can see an object 2 feet long on the earth.

Will you set me straight on it?

Mr. QUARLES. On the point that we could not object, I meant to speak here as a military man rather than as an international lawyer. I would not like to say that the State Department would feel they could not object. I do not know whether they would feel they could object, or not.

I know in a military sense it seems to me that objects orbiting in outer space have an international character by the very nature of their position there and that it would be inappropriate for us to take the position that what you could see from there of our area would be improper for them to see any more than it would be improper for a reconnaissance group stationed on the moon to use a spyglass to look at us.

I just think we cannot establish that kind of position that these are improper or objectionable or offensive.

So I would have the view that we would not seek to object to such reconnaissance.

Mr. KEATING. That is all, Mr. Chairman.

The CHAIRMAN. Mr. Ford.

Mr. FORD. Mr. Secretary, in the declaration of policy on page 2, there is this sentence:

> The Congress further declares that such activity should be directed by a civilian agency exercising control over aeronautical space research sponsored by the United States except insofar as such activities may be peculiar to, or primarily associated with, weapons systems or military operations, in which case the agency may act in cooperation with, or on behalf of, the Department of Defense.

In your opinion, does that declaration of policy in any way run contrary to or inhibit what you feel is the rightful area of the Department of Defense?

Mr. QUARLES. Again, not speaking as a lawyer, but in my own appraisal of the position, I would say that if the legislative history makes it clear that there is no intent in this phrase to imply a prohibition, then it would be all right because it can certainly be interpreted to give the latitude that I would think appropriate, the latitude of judgment as between Defense and the civilian agency.

However, if the legislative history tended to make you construe that phrase narrowly as a kind of prohibition against defense, I would find it not in the national interest, for this reason:

The Defense Department, it seems to me, must have the latitude to pursue those things that are clearly associated with defense objective as stated here. It must also have the latitude to pursue things that are potentially important to defense and to pursue those within the Defense Department or in cooperation with, for example, the civilian agency, if it is covering the subject matter.

I would think that a narrow construction which could be cited against Defense if they get just a little bit over the line here, would be not in the national security interest, and, therefore, not in the national interest, and I would recommend against such a narrow construction.

But I do not believe these words necessarily must be so narrowly construed

Mr. FORD. It would appear to me from a reading of that language that the Department of Defense is given more or less the authority to make such a decision. That is certainly the way I feel it should be construed. Any other construction would be a very narrow prohibitive construction, so far as words are concerned.

Mr. QUARLES. This is why, Mr. Ford, I hedged a little bit on your question because I am not quite sure how it would be construed in the absence of statements such as the one you have just made in the legislative record back of this legislation.

I think it is important to recognize that the agencies have been, or are being established by the Congress, to serve the national interest in their respective spheres and what the Congress and the people are looking for is the maximum national interest.

And too rigid a line between them would not in my opinion serve the maximum national interest.

Mr. FORD. It seems to me from the testimony we have had and the comments I have heard from the various members of the committee when we discussed this language, that there is no disposition on the part of this committee to restrict that language so that the Department of Defense is inhibited in any way whatsoever.

As a matter of fact, it is my recollection most of the members have expressed a desire that that language be crystal clear in this regard so as to give the Department of Defense certain latitude necessary to its operation.

Mr. QUARLES. Mr. Ford, I wonder if I might pursue that point a little bit further.

The CHAIRMAN. You will have the opportunity of reviewing your remarks, Mr. Secretary, when you edit them and you can elaborate or add thereto and we hope you will.

We realize when you are asked questions and you answer extemporaneously that it is a different proposition than if you were putting down in writing your reflective and mature thoughts.

Mr. QUARLES. I would only like to bring out, if I may at this time, the point that the President in Executive Order 10521 establishing basic research functions—and this, Mr. Chairman, you, yourself, are very familiar with—made it a function of the National Science Foundation to be the central point for the support of basic research in the Federal Government, but charged each one of the executive departments with such support of basic research as would be appropriate in the fields of basic research underlying their particular activities.

I think one should have this same general philosophy in approaching this matter as well as basic research more broadly.

Mr. FORD. Mr. Secretary, you have had a great deal of experience with research and development in the military and with funding problems. I presume you would concur in the language in section 9 (a) which gives this Agency no-year fund authority in contrast to 1-year fund authority.

Mr. QUARLES. I would very definitely, yes, Mr. Ford.

Mr. FORD. Would it be detrimental to the progress of the agency if it had only 1-year fund authority?

Mr. QUARLES. I would feel that it would either be detrimental to the agency, or would not make the best use of the appropriated funds.

Mr. FORD. Thank you very much.

The CHAIRMAN. Mr. Secretary, I am going to give you some questions in writing which I would like you to think over. It relates to the declaration of policy, page 2, point 6:

> Cooperation by the United States with other nations and groups of nations in work done pursuant to this act and in the peaceful application of the results thereof.

Further on, section 6, paragraph 4, on the functions of the agency, the bill states that the Agency shall:

> Arrange for participation by the scientific community in planning scientific measurements and observations—

and so forth.

One of the questions is: Should the power to cooperate with individuals or groups abroad be authorized?

You see, it is on a nation-to-nation level.

Furthermore, what is your definition of a "scientific community"? That is very important. How would you define "scientific community"?

Is it the scientific community of the United States, or whatever relationships might be entered into abroad? Would the new Director of the Space Agency disseminate an underlying policy of the department and the AEC?

In other words, foreign policy might be involved. That should be given consideration in connection with the drafting and reporting of the bill.

What arrangements will the new Space Agency make with other Government bodies in implementing cooperation with other nations in the dissemination of data? What would be its official relationship with the Soviet Union?

In answering these questions, will you also send me a letter so that I will have it directly?

Mr. QUARLES. Of course I shall be glad to, Mr. Chairman.

The CHAIRMAN. I wish you would look over the bill and see if you have any suggestions to offer as to why it should be changed or strengthened. We would welcome that very much.

Now, some of these questions that Mr. Ford asked you regarding page 2:

Except insofar as such activities may be peculiar to, or primarily associated with, military weapons systems or military operations—

we start out by establishing a civilian agency and say: "except," in which case they must be confined to activities which may be peculiar to, or primarily associated with, military systems.

Who is to judge? Suppose there is an honest difference of opinion, to whom would they go to make the decision?

Mr. QUARLES. Mr. Chairman, we have been working with this same general line of division with the National Advisory Committee for Aeronautics. I do not say that a legal definition has been the same, but the concept has been the same.

This has been going on for many years. To the best of my knowledge there has never been a need for referring a dispute to any higher authority, we have always agreed.

The CHAIRMAN. Of course, research and development has not been so intense as it is now. Because it was not so intense, the complicated questions did not arise.

Mr. QUARLES. Perhaps we are moving into a more difficult period and with more likelihood of a dissent arising. I only mean to point out that I think it is not too likely that we will be unable to reach agreements among ourselves about these matters as between the two agencies, but in the event that we cannot, it seems to me to be clearly a matter for Presidential determination; Again, of course, using his advisers to assist in that determination.

The CHAIRMAN. Of course, the President cannot pass on every question, but it would be the President or somebody designated by him. I assume that is what you have in mind?

Mr. QUARLES. In the last resort the President is always there to make the determination. It would be very poor administration if we referred each one literally to him, of course.

The CHAIRMAN. I am a great believer, under our constitutional setup, in preserving the rights of the President. We have over here provisions for reorganization in the next 3 years. Suppose the agency wants something to come under the NASA that is part of the Science Foundation or part of ARPA? Then it has to be approved by the Defense Department and the Science Foundation, there is a veto power there, and then it is subject to approval by the President.

Do you not think the President should be the top man? That should be a matter of phraseology. We can take care of that matter very easily, but I would like your opinion for the record.

Mr. QUARLES. I think he should be, and I must say I read the legislation as making him such.

The CHAIRMAN. It is a hard thing to draft. It is easy to examine a draft and pick out any weakness.

Mr. Fulton?

Mr. FULTON. I have several short questions.

Should we on this committee not see that ARPA has the right to do extensive basic research, as distinguished from weaponry programs?

Mr. QUARLES. I would say that we should not exclude ARPA from basic research, Mr. Fulton; that is right.

Mr. FULTON. Would you then for the record, rather than doing it now, give us the form of language which would make sure in legislation that ARPA would have the right to continue basic research which might eventually lead to weaponry?

The CHAIRMAN. Does not ARPA have the authority to make basic research?

Mr. QUARLES. I would say that it now does, but of course, it is conceivable that in this field of aeronautics and space research one might construe this legislation as excluding ARPA from it. I shall be very glad, however, to give you a suggestion along that line.

The CHAIRMAN. I am sure there is nobody in this committee who would think of that because we recognize the practical situation in the world today.

We must have our civilian agency and I am for it, but we must recognize the importance in the world today of a strong Military Establishment, up to date in all ways.

Mr. QUARLES. I think the important thing here is to see in NASA a research and exploratory development agency which would probably carry the great bulk of the load, of the research load in this field, and carry it equally for ARPA and for civilian agencies, but I would not think it wise, and I do not believe they would think it wise, to have any exclusion of ARPA from supporting research if that seemed to be appropriate, understanding that it would be coordinated with the program of NASA.

The CHAIRMAN. I do not think Mr. Fulton's question was on any theory of exclusion.

Mr. FULTON. You see, your point, Mr. Chairman, of the word "except" on page 2, line 7, brings into complete focus whether there is an exclusion of one from the other because when we read further:

except insofar as activities may be peculiar to, or primarily associated with, weapons systems or military operations—

it might exclude ARPA from basic research that has no immediate military application.

So that following on the chairman's point, if you could submit us language along that line, it would be appreciated.

The CHAIRMAN. I had not thought of that, but certainly there is nobody on this committee who is even remotely thinking of that. Will you give us some language on that?

Mr. QUARLES. I shall be glad to study that and report to you, Mr. Chairman.

Mr. FULTON. Of course, on advancing the national space policy, we should not in any way supersede or remove the present strategic security resources of the United States that are in the military forces, should we?

Mr. QUARLES. I certainly feel we should not, and in fact, great care should be exercised not to lose any momentum in the transition.

Mr. FULTON. And we, therefore, should have other programs developed rather than cut out programs that are now underway in ARPA and other agencies, if we can.

25973—58——71

Mr. QUARLES. Well, I think some of the programs we have started in Defense, we would consider quite appropriate for the other agencies to take over when they are ready to do so.

Mr. FULTON. That is right. We should not by this program start relying on space agency equipment and give up something that is now defending us basically.

Mr. QUARLES. I agree completely.

Mr. FULTON. For the immediate future, 3 to 5 years, the Strategic Air Command and its B–52's are just as necessary as we think the missiles might be.

Mr. QUARLES. They certainly are and I see nothing in that time period that could relieve the B–52 of its burden.

Mr. FULTON. You would not suggest that we change over to AEC directorship at this time, would you?

Mr. QUARLES. No, I would not make that suggestion. I perhaps was not too careful in phrasing my response.

When I spoke of the directorship I was speaking directly to this Agency.

Mr. FULTON. On a national space policy should that be established overall by a civilian agency, for everybody, including the military, with, of course, the right of operations in the military and the military planning to be done by the Department of Defense, its various organizations and services?

Mr. QUARLES. I would say not. I would say that the President as the Commander in Chief working with the Secretary of Defense, must preserve that line for the establishment of defense policy and there should be no other agency that in any sense could intervene in that line of policy determination of defense matters.

Mr. FULTON. A previous witness suggested that the exchange of information, through the translation of books, magazines and periodicals, should be under the United States Information Agency. I would question that because that happens to be a United States instrument of policy in foreign affairs and might have a relationship to a cold or economic war or a propaganda purpose.

Would it be possible for an outside agency to take over these functions, possibly part of the Space Agency? The Library of Congress could handle it.

Mr. QUARLES. As you know, Mr. Fulton, there is in the Library of Congress an agency of that kind. There is also such an agency in the Department of Commerce.

Mr. FULTON. We have Dr. Sheldon on our staff from the Library of Congress. I mean broadening the scope to take over the overall gamut of a national space program.

Mr. QUARLES. I would suggest that insofar as you are dealing with basic science and publishable scientific information, it would be well to either vest that in the new Agency or let the new Agency work with such an organization as the one already established in Commerce to carry on this interchange.

However, in respect to material that includes national secrets that should be secured under our National Secrets Act, whether they be restricted data or military secrets.

I think that the agencies presently responsible for security of that information and for the interchange of such information with for-

eign countries should remain responsible for it and that that should not be delegated to a new agency.

Mr. FULTON. I congratulate the United States Air Force on the publication in March 1958 of its glossary of scientific terms in the astronautics field. I think it is a good thing.

Mr. KEATING. Mr. Chairman, could I ask just one question?

Mr. NATCHER (presiding). Mr. Keating.

Mr. KEATING. We do have a program, do we not, for the development of an antisatellite missile or what we might call an antimissile missile?

Mr. QUARLES. We have a program for the development of an antimissile missile that I suppose could be construed as potentially a program for the development of an antisatellite missile, but that would be stretching the project pretty far, Mr. Keating.

I think it would be better to regard it as a project for an antiballistic missile system or missile.

Mr. KEATING. In other words, it is directed against a weapon and not against a satellite. Is that it?

Mr. QUARLES. That is right, and the distinction really is that the weapon is reentering the atmosphere and getting within range of a target that it may be attacking and the problem of destroying a weapon that is reentering the atmosphere is quite a different problem from that of destroying a satellite that might be several hundred miles away from the surface of the earth at all times.

Mr. KEATING. And it is not directed under our present program against satellites which might be flying several hundred miles up in the air over the country?

Mr. QUARLES. Our project as presently organized is not so directed, although there are people connected with the project who are thinking about the larger problem.

Mr. KEATING. That is all, Mr. Chairman.

Mr. NATCHER. Mr. Sisk, I believe you have one additional question?

Mr. SISK. Thank you, Mr. Chairman.

Mr. Secretary, I am asking these questions in the light of testimony just ahead of yours by Dr. Dornberger. The question is this:

If the Department of Defense has had the Dynasoar project since 1951, available for development, why is it that it just now is getting ready to move on that? Can you make any comment on that at all?

Mr. QUARLES. I can, Mr. Sisk, in this sense: The Department of Defense, in this case the Air Force was the responsible agency, has, of course, a great multitude of proposals that are made to them that are being evaluated by the Department as to either immediate value or long-range exploratory value. While, of course, the judgment in evaluating these things is not infallible, it is still the best judgment we can bring to bear on it. I can only say that this project was not authorized and prosecuted simply because it was not given values to justify such prosecution.

Mr. SISK. In view of recent actions on project Dynasoar by your Department, do you expect contract awards to be announced soon?

Mr. QUARLES. The project is with the Air Force and an Air Force recommendation has not come to Defense on it. So I would be getting ahead of myself to predict what the Air Force will do.

I believe I know that they are interested in certain preliminary work on this project, so I would not be surprised at a recommendation

that we pursue it, to limit it to objectives, but I have not received that recommendation yet, Mr. Sisk, so I really am not in a position to respond definitely.

Mr. SISK. Thank you, Mr. Chairman.

Mr. NATCHER. Mr. Feldman.

Mr. FELDMAN. Mr. Quarles, in response to a previous question, you said it was important to establish a continuous collaboration between the agencies. I assume you meant between the military and the new NASA setup?

Mr. QUARLES. That is right, Mr. Feldman.

Mr. FELDMAN. What is your understanding of liaison, the function of liaison?

Mr. QUARLES. Well, just abstractly, do you mean now, without any particular reference to this situation?

Mr. FELDMAN. Without any reference to this situation, yes.

Mr. QUARLES. My understanding is that when we have 2 organizations which have extensive dealings with each other, or important relationships between them, that it may very well be justifiable to set up a liaison agency which would be 1 or more persons charged specifically with moving back and forth between the 2 organizations to make sure that each to a maximum degree is informed of the operations and activities of the other.

Mr. FELDMAN. In other words, there is a flow of information between both organizations in order to prevent unnecessary duplication, so that the right hand knows what the left hand is doing?

Mr. QUARLES. I would say that is the fundamental and primary purpose of a liaison agency, yes.

Mr. FELDMAN. In order for liaison to be effective, it should be continuous. Is that not so?

Mr. QUARLES. Yes, I would say that is so, but I believe you are leading me into an implication there that I do not quite agree with, so I had better be more explicit.

In order for liaison to be effective it must be as continuous as the circumstances require.

Now, I can imagine organizations which would have such infrequent liaison that you would not justify setting up of a particular group charged with that purpose.

If you will allow me to define continuous as meaning there should be no interruption of it, then I agree.

Mr. FELDMAN. You have language in statutes which contain the exception that was read to you before, namely—

except insofar as such activities that may be peculiar to, or primarily associated with, weapons systems or military operations, in which case the agency may act in cooperation with, or on behalf of, the Department of Defense.

I continued to read from the memorandum for the Secretary of Defense and the Chairman of the National Advisory Committee for Aeronautics, dated April 2, 1958—I am now reading from the next to the last sentence in the third paragraph:

However, it is appropriate that a civilian agency of the Government take the lead in these activities related to space, which extend beyond the responsibilities customarily considered to be those of the military organization.

Now, those are terms and we know, of course, in this situation there is a good deal of overlapping and also a good deal of cointerest in many of the projects.

In other words, the military is as interested in weather as a nonmilitary agency. The military is as interested in communications as is a nonmilitary agency.

So a myriad of problems will arise and they will need direct scrutiny.

Mr. QUARLES. I think we would need direct scrutiny, yes.

Mr. FELDMAN. Are you acquainted with the liaison that exists between the military and the AEC?

Mr. QUARLES. I am well acquainted with it, Mr. Feldman.

Mr. FELDMAN. Has it functioned well?

Mr. QUARLES. I would say it has functioned well.

Mr. FELDMAN. Is it continuous?

Mr. QUARLES. Yes, because the military liaison committee is in continuous session.

Mr. FELDMAN. Would you object to the inclusion in this legislation of a provision similar to the one contained in the Atomic Energy Act of 1954, which is pretty broad in scope?

Mr. QUARLES. I would say in my best knowledge it is not needed as a portion of the act and that the act would be better legislation without it, in my opinion, for this reason, Mr. Feldman: Liaison is best accomplished where it is possible for the heads of the agencies themselves to have direct dealings and understandings with each other. Any time they have to set up an intermediary they are compromising. They are recognizing that they do not have time themselves to deal with each other.

Now at least initially, I believe that General Doolittle and Dr. Dryden, who are now on the NACA side, and Mr. Johnson and Dr. York here, who are now on the ARPA side, can to much better advantage establish their direct liaison relationships rather than having a statutory intermediary between them.

So I would recommend against the establishment of a statutory liaison agency between Defense and this organization. I do not say that we could not make it work, but I go along with the theory that in Government it is better to have as few agencies as possible and this is one I do not now see a need for.

Mr. FELDMAN. This would necessarily be a separate agency, but if a great number of these problems arise, that would be rather time consuming; is that not so? I know that in business the head of a large company would not undertake to do the labor-relations work of that organization.

I know from my own experience that whenever an attempt was made to have the head of a large company engage in labor relations it meant that for all times in the future he had to be the labor-relations representative for the company. It would be so time consuming that he would never have any time to do anything else.

Now, the same thing could arise here and the result, of course, would be that his time would be consumed along those lines. You do not see, for example, George Meany, who is the head of the AFL–CIO, or Mr. Reuther engaging in personal negotiations with labor-relations representatives of companies. They stay in the background. They let somebody else down the line iron out the details and then come to them with the big problems. I am just speaking now from the organizational point of view. I am not wedded to the idea, but I am trying to evolve something that will be effective.

That leads me to this question. Under the new proposed Agency setup the Board is to meet no more than four times a year. The Board must contain one military member. On that basis I think General Doolittle stated that liaison would be automatic.

Now, assuming that the Board met 10 times a year, do you think that that single member of the Board from the military or 3 members from the military meeting 10 times a year would be able to make that liaison automatic?

Mr. QUARLES. No; I do not think that liaison through the Board would be a proper concept, I agree, and a Board member would not in my concept be an appropriate liaison of the kind you are speaking of. Might I carry that point a little farther and say that I am sure that the heads of the agencies found they did not have time or as the relationships got more intricate and time consuming they could establish working relations between them without the need for any legislative instructions or definitions as to just how they should do so.

That would be my only point on the matter, Mr. Feldman.

Mr. FELDMAN. Well, then, we will have the heads of the different agencies occupied with continuous meetings. What harm would there be, then, in having that provision in the law?

Mr. QUARLES. I did not mean to say that I envisaged a specific liaison organization between the agencies. I do envisage a liaison arrangement between the agencies. I think to define it in the statue would be undesirable because you might very well want to start out with some very simple arrangement that did not involve a separate organization and you might later want to evolve toward the delegation of the function to some subordinate official of each organization.

I just think it would be better not to define it in the law. I do not see a statutory purpose that such liaison committee would serve.

The CHAIRMAN. Is it not almost certain, because of the general language I read to you before, that you will have to have some liaison setup?

Mr. QUARLES. I think you will have to have some liaison, but when you say set up you imply to me a specific organization solely for that purpose and that I would say I do not see the need for.

Mr. FELDMAN. Would you revise the Atomic Energy Act and not have the Statutory Liaison Committee?

Mr. QUARLES. From where we are today and knowing what has been involved in revising the Atomic Energy Act, I would not recommend such a thing. But I do not feel that you are dealing with an analogous situation here. There were certain principles in the original act primarily related to a sense of special security and special national interest in the security of atomic secrets that led to that whole organization and I do not think you have a parallel situation here, and I therefore would not like to argue by analogy that we should have a military liaison committee here because we had one there.

Mr. FELDMAN. I do not think that is the only reason that led to the establishment of that committee in law itself. I think one of the requirements was because the military had a pretty big stake in the program and they wanted to continue that stake. My own thought is that it might be better served by having such a liaison committee established in the law itself.

However, as I say, I am not wedded to the proposition and I am in the nature of a devil's advocate trying to find out.

Mr. QUARLES. Mr. Feldman, I have given you my best judgment on it.

Mr. FELDMAN. The President's bill provides, and I am referring again to section 2, for exclusive civilian control—

except insofar as activities may be peculiar to, or primarily associated with, weapons systems and military operations.

Now, approximately what proportion of the activities of the outer space agency do you anticipate would come within that exception?

Let us put it this way: Would it be a substantial part or small part?

Mr. QUARLES. To be sure I understand your question, of course those things that came within the exception would not come within the outer space agency. So may I answer in this sense, that what fraction of the total national space program would fall within the civilian agency and what fraction would fall within the military under this definition—may I answer it that way, Mr. Feldman?

Mr. FELDMAN. That is right.

Mr. QUARLES. Initially I would expect that the majority of the program in this field, the majority dollarwise of the program, would be military. Perhaps as much as 75 percent would initially be military. I would expect the civilian percentage to build up proportionately over the years.

I do not think I can look down the road very far in this matter, but at any rate I would say that as far as I can see, one would expect a substantial fraction of the project work to be military project work in the sense of this proposed legislation.

Mr. FELDMAN. Assuming the language were changed to read: "Pertaining to weapons systems or military operations," would you answer me the same?

Mr. QUARLES. My answer would be the same because as I discussed with Mr. Ford earlier, I am construing and I hope we may construe these words broadly in defining the areas of the two agencies.

Mr. FELDMAN. Now, assume, for example, that the outer space agency would take over the Vanguard and the Redstone projects under its contract and lease authority on page 8, subsection 6 (5), or its transfer authority, page 15, section 8. Should it do so, in your opinion, or should those projects remain under military control?

Mr. QUARLES. On the Vanguard project the answer would be solely a matter of timing. I think the Vanguard project as we visualize it now will not be one that enough is left of to make it appropriate for this agency to take it over when the Agency is ready to go as an operating agency. I am not quite sure I know what project counsel refers to in the Redstone project.

Mr. FELDMAN. I mean the whole Redstone project.

Mr. QUARLES. The Redstone project in my definition, Mr. Feldman, is a Redstone missile project which is entirely military and entirely inappropriate for the Agency to take over, but I may misunderstand it.

Mr. FELDMAN. The language says, "On behalf of the Department of Defense."

Mr. QUARLES. Perhaps you have in mind that the new civilian agency might take over some part of the Army Ballistic Missile Agency at the Redstone Arsensal. If that is what is meant by Redstone, then

I think that they could do that as soon as they are ready and as soon as they have projects that would be appropriate for the Ballistic Missile Agency to undertake.

Mr. FELDMAN. Well, there is a possible construction of those words, "on behalf of the Department of Defense" which would enable the civilian agency to take over.

Mr. QUARLES. If I construed "on behalf of" as meaning that if by agreement it looked best for them to take it over, would this not be a fair construction?

Mr. FELDMAN. Not necessarily. If you have those words inserted in the statute itself, it would obviate the need for that kind of interpretation.

Mr. QUARLES. I thought if a man did something on my behalf it was because I wanted it. I did not know he just could do it.

Mr. FELDMAN. If you give him the authority to do it on your behalf, he can decide that for himself.

Mr. QUARLES. Sir, you know better than I.

Mr. FELDMAN. In your opinion, to take a further example, what agency should have charge of developing a million pound thrust rocket, the outer space agency, ARPA, or the AEC?

Mr. QUARLES. That project today is a joint project in which NACA carries certain aspects of it and the Air Force is the contracting agency for contracting work in that field.

I would find that to be the desirable organization of the project for the time being, but I do not at all exclude a more positive control of the project by NASA when and if that organization is operating. Really today they work so closely together it would be hard to say which organization is controlling it.

Mr. FELDMAN. The President's bill contains authority to operate as well as to develop and test aeronautical and space vehicles. I refer to page 6, lines 1 and 2, page 7, lines 7 and 8.

In your opinion, does the Outer Space Agency need such authority?

Mr. QUARLES. I feel, Mr. Feldman, that they do need the authority to operate. I think, however, the language should not imply an exclusive authority to operate. As I say, again, I think, it can be presently construed as not being exclusive and if we may so construe it, then I agree with the language.

Mr. FELDMAN. But if it does not, why you would think it should be changed in that respect?

Mr. QUARLES. I do not think it should be given exclusive authority to operate in this field.

Mr. FELDMAN. Does not the NACA have authority to operate aeronautical vehicles now?

Mr. QUARLES. It does have. I have not examined the law, but I know in fact it does operate such vehicles so I am quite sure it has the authority to do so. And I think it should have although most of these aeronautical vehicles are joint projects in which one of the military services actually operate the vehicle in a joint enterprise with NACA.

Mr. FELDMAN. The NACA Board at the present time is the executive group within the Agency. The director serves under the Board. The new proposal makes the director the top executive and the board's function is primarily advisory. Do you have any thoughts in that connection?

Mr. QUARLES. I am frank to say that I was surprised when I read this part of the legislation and wondered just what was meant by it. I believe that the intent here was to be sure that there would be vested in the director the authority to proceed expeditiously with the work.

Of course, with that we are all in sympathy. I think, also, there was the intent that the director should be responsive to the chief executive and that there should be no intermediary board that could intervene between the director and the chief executive.

Also, with this I am in thorough agreement. I do think that the present NACA arrangement has been a constructive one in which a governing committee has in effect set policy for the committee and its operations.

Mr. FELDMAN. I have heard it said that one of the reasons for the creation of this new agency was because of the success of the sputniks and the so-called public hysteria which resulted at that time, and that there was no need for any high level agency to operate in the space field except to calm that hysteria.

Do you agree with that conclusion, Mr. Quarles?

Mr. QUARLES. I cannot say there was no hysteria at the time of the sputniks, but I do not agree that this legislation was based on such hysteria. I think that there is a sound need for a civilian agency in this field. I would say there is, and quite aside from sputniks, I support a civilian agency for an appropriate part of this work.

Mr. FELDMAN. And it should be on a high level, is that not so?

Mr. QUARLES. I think the level on which it is cast by this legislation is appropriate, yes.

Mr. FELDMAN. Not higher than that?

Mr. QUARLES. I do not think it need be any higher level than it is. I said earlier that I did not see a need, for example, for permanent membership on the National Security Council of the head or the director of that Agency.

Mr. FELDMAN. The Atomic Energy Act contains rather detailed provisions, referring now to chapters 11, sections 121 through 125, for international agreements on cooperation and provisions for indemnification up to an aggregate amount of $500 million and limitation of liability. I am referring here to section 170.

In your opinion, should the President's bill be amended so as to include similar provisions? I am not talking about any $500 million limit on aggregate liability, but some such provision.

Mr. QUARLES. Mr. Feldman, I would say there is not here a reason for indemnification in such large amounts that there was in the Atomic Energy case. I think that the matter of indemnification should be covered either in this or in general legislation. As you perhaps know, we have a bill, now pending before the House Armed Services Committee on this broad point as far as defense is concerned.

Mr. FELDMAN. Would it cover this civilian agency?

Mr. QUARLES. I am not sure of that, but I will be glad to go back and make sure of that. There is no doubt that broad legislation on indemnification should cover such an agency as well as defense.

Now, on sections 123 and 125 of the Atomic Energy Act that deal with agreements for international cooperation, these sections are addressed almost entirely, as I recall, to the problem of maintaining the security of restricted data and at the same time allowing enough

latitude, what the Congress deemed to be proper latitude, in making agreement with other countries in the handling of restricted data.

I would not see a reason for paragraphs of that kind in this act because, as I think I said to Mr. Ford, it would seem proper to me that we leave the responsibility for handling of national secrets where it now is and not vested in this Agency.

In other words, if they are national secrets in the restricted data area the responsibility would remain in the Atomic Energy Commission.

If they are in the military area other than restricted data, it would be in the Defense Department, and in respect to interchange with foreign countries or foreign nations, the State Department, of course, becomes one of the agencies jointly responsible for it.

We have regulations now that set all of this forth. I would think it would be well to let the handling of these secrets remain where it now is and leave this Agency in a field of unclassified work rather than have classified work as far as international agreements are concerned.

Mr. FELDMAN. I have no further questions.

Mr. NATCHER (presiding). Mr. Secretary, on behalf of our chairman, Mr. McCormack, and the other members of the committee, I want to thank you for the fine statement you have made and for your appearance before our committee at this time.

The committee will adjourn until 10 o'clock in the morning.

Mr. QUARLES. Thank you, Mr. Chairman.

(In response to various requests for information Mr. Quarles submitted the following material:)

THE DEPUTY SECRETARY OF DEFENSE,
Washington, D. C., May 19, 1958.

Hon. JOHN W. MCCORMACK,
Chairman, Select Committee on Space and Astronautics,
House of Representatives.

DEAR MR. CHAIRMAN: This is in response to requests made during the course of my testimony before the Select Committee on Space and Astronautics for additional information.

The question was raised as to whether the Advanced Research Projects Agency would have the right, under the proposed legislation, to continue basic research. I stated at that time it was my opinion that the language of the bill would preserve the right of ARPA to undertake required basic research. I understand that during subsequent hearings on the bill Mr. Dechert, our General Counsel, and Mr. Roy Johnson, Director of ARPA, submitted language which would make clear that activities peculiar to or primarily associated with weapons systems or military operations will be the responsibility of the Department of Defense. This suggested amendment, read in conjunction with Executive Order 10521 would, in my opinion, remove any doubt that might have previously existed as to the authority of the Department of Defense to engage in required basic research.

The indemnification legislation to which I referred is H. R. 11639, now pending before the House Committee on Armed Services. This proposed legislation would not specifically cover contracts of the proposed new Space Agency except in those instances where the proposed Agency and the Department of Defense entered into a joint undertaking with the Department of Defense acting as the contracting agency.

I am attaching hereto as a separate statement responses to your specific questions with respect to international cooperation.

Sincerely yours,

DONALD A. QUARLES.

ANSWERS TO QUESTIONS POSED BY HOUSE SELECT COMMITTEE ON ASTRONAUTICS AND SPACE EXPLORATION

1. In the declaration of policy, point (6) states that a policy objective is "cooperation by the United States with other nations and groups of nations in work done pursuant to this Act and in the peaceful application of the results thereof * * *"

Question. Should cooperation with individuals and groups abroad be authorized?

Question. How do you think the Director of the new Agency would implement point (6) in the declaration of policy? (The bill does not contain implementation of this policy on level of nations.)

Answer. The statement of policy objectives, including point (6), is interpreted as defining national objectives and not necessarily the functions of the new Agency. For example, it seems unlikely that cooperation with "other nations and groups of nations" would be carried out directly by NASA, except to the extent that the State Department had established channels for such cooperation. There would appear to be no need in the statement of policy to extend point (6) to include cooperation with individuals and groups in other nations, since this is implicit in cooperation "by the United States with other nations." The "work done pursuant to this Act and in the peaceful application of the results thereof" is interpreted to be work of an unclassified scientific character and is interpreted not to include national secrets either of a military or atomic energy kind.

2. In section 6 on functions of the Agency, the bill states in point (4) that the agency shall "arrange for participation by the scientific community in planning scientific measurements and observations to be made through use of aeronautical and space vehicles, and conduct or arrange for the conduct of such measurements and observations; and provide as appropriate for dissemination of data collected; * * *"

Question. How would you define "Scientific Community"?

Would the new Director of the Space Agency disseminate data in line with the policies of the State Department and AEC?

What arrangements would the new Space Agency make with other Government bodies in implementing cooperation with other nations and the dissemination of data? What would be its official relationship with the Soviet Union?

Answers. "Scientific Community" means all scientists interested in research in this particular field (aeronautical and space sciences) and organizations of, or representing, such scientists. "Scientific Community" would be international in extent unless otherwise restricted.

Dissemination of data by the new Director would be controlled by executive branch policy, presumably an Executive order. While such policy has not been laid down, it could well continue the present Defense Department and AEC responsibilities for the securing of their respective national secrets. In the disclosure of such secrets to other nations or foreign nationals, State Department would join Defense and AEC in establishing policies and procedures. Since the new Space Agency would be primarily concerned with research in the aeronautical and space sciences and not with those applications of military significance, the data which the Director of the Space Agency would disseminate would presumably be unclassified data. Whether the new Space Agency would disseminate such data to other nations and foreign nationals directly or through one of the existing agencies for such dissemination could be properly left for executive branch determination.

As regards official relationship of the new Space Agency with the Soviet Union, this again would be a matter for executive branch determination. As a generality, it can be said that the new Agency would have only such relationships with the Soviet Union or its nationals as might be arranged by the State Department in accord with national policy. Establishing appropriate policy and procedures would be a proper function of the Executive by Executive order or otherwise.

(Whereupon at 5:20 p. m. the committee recessed to reconvene at 10 a. m. Thursday, May 1, 1958.)

ASTRONAUTICS AND SPACE EXPLORATION

THURSDAY, MAY 1, 1958

HOUSE OF REPRESENTATIVES,
SELECT COMMITTEE ON ASTRONAUTICS
AND SPACE EXPLORATION,
Washington, D. C.

The committee met at 10 a. m., pursuant to recess, in the caucus room, Old House Office Building, Hon. John W. McCormack (chairman) presiding.

Present: Representatives McCormack, Natcher, Fulton, Keating, and Ford.

Present also: George J. Feldman, director and chief counsel.

The CHAIRMAN. The committee will be in order.

The first witness will be Dr. Joseph Kaplan, professor of physics at the University of California, and Chairman of the United States Committee for the International Geophysical Year.

We are very glad to have you with us, Doctor. Have you a prepared statement, or do you want to talk from notes?

STATEMENT OF DR. JOSEPH KAPLAN,[31] PROFESSOR OF PHYSICS, UNIVERSITY OF CALIFORNIA, LOS ANGELES, CALIF., AND CHAIRMAN, UNITED STATES NATIONAL COMMITTEE FOR THE INTERNATIONAL GEOPHYSICAL YEAR

Dr. KAPLAN. I would like to talk entirely informally. I think I am probably one of the few witnesses you have had before this committee who can say honestly he is glad to be here, considering the difficulty I had getting here.

The CHAIRMAN. I understand you were up in the air a lot; outside of your years of education and training and so forth, you recently have had an experience where you were up in the air.

Dr. KAPLAN. Actually, it proves dramatically once more the need for the IGY and for a better understanding of the weather close to the surface of the ground, which is perhaps a strange thing to say at a hearing on space, but one of the problems as always in a case of this sort, is accurate short-range weather forecasting and that is still with us, even in the age of space science.

[31] Kaplan, Joseph, prof. physics; b. Tapolcza, Hungary, Sept 8, 1902, s. Henry and Rosa (Lowy) K brought to U. S , 1910, B. S., Johns Hopkins, 1924, A. M., 1926, Ph. D., 1927, m. Katherine E. Feraud, June 24, 1933. Research fellow, Princeton, 1927; asst. prof. of physics, U. of Calif., 1928-35, asso prof., 1935-40, prof since 1940, chmn. dept. of physics and meteorology, 1938-44, director of Inst of Geophysics 1946-47; national Sigma Xi lecturer, 1948-49. On war leave with Army Air Forces since 1940, chmn. panel on geophys. research Sci. Adv. Bd. U. S. Air Force. Decorated for exceptional Civilian service, War Dept ; 1947, Achievement Award from Tau Delta Phi Discoverer of laboratory productions of auroral spectrum and light of night sky Chmn West Los Angeles Co-ordinating Council. Soc. of the Pacific, Soc. for Research on Meteorites, Optical Society of America, American Meteorological Society, Institute of the Aeronautical Sciences, Tau Beta Pi, Tau Delta Phi, Scabbard and Blade. Republican Jewish religion. Club. West Los Angeles Rotary (v. p. 1937, pres. 1938). Co-author: Physics and Medicine of the Upper Atmosphere, 1951; Across the Space Frontier, 1951 Contbr. articles to Phys Rev and other sci. publs.‡ ☆ [27]

I realize that in your previous hearings many things have been mentioned as far as the satellite program as proposed by the IGY is concerned, its further plans and so on.

I would like to stress one point that I think has impressed me most strongly in thinking about this problem and that is the point relating to the training and the proper use of the kind of young scientists whom we will need to carry out any kind of an effective program in the exploration of space

The related fields, particularly meteorology, upper atmospheric physics, ionospheric physics, and so on, are fields in which there are relatively very few people active.

I have had a recent experience, for example, of turning out one of the most brilliant young doctors of philosophy in this area, only to have him drafted by an applied laboratory at a salary which is approximately twice as much as he would get in any first-class university and, therefore, he was taken out of circulation insofar as developing himself or doing fundamental research is concerned.

The present proposal to expand the NACA into a larger agency appeals to me personally because of a long and pleasant association with the NACA. I know the quality of their personnel.

As a matter of fact, I have had personal experience of them in years past and was associated with them on some of the new problems of the high atmosphere, 20 or so years ago, and have seen the quality of their scientists and engineers.

I think one of the associated problems, however, is that associated with this proposal should be a thorough thinking and complete revision of the research structure and the use of Federal funds in this area.

I would like to specify as quickly as I can what I mean. I feel very strongly that the Military Establishment, the Air Force, the Navy, the Army, must have first-class research laboratories of the quality of NRL, the Geophysics Research Directorate of the Air Force and the Signal Corps Laboratory of the Army.

I think they ought to be as good as any university laboratory.

The military, the people in the Air Force, the Army, and Navy, ought to have available to them the best scientists in the country.

Now, this has been approximated to my intimate knowledge. Since I have worked at or with two of these institutions, the Naval Research Laboratory and the Geophysics Research Directorate in the past years, I think we have been somewhat close to it, but not close enough. Some of the first-class scientists today working on rocket and space problems at NRL and the Geophysics Research Directorate of the Air Force are men whom I would like to proselytize for the university, but I won't do that, because I don't want to hurt the military.

But there are not enough of them and they should be supported in the same sense that the best scientists in the Nation should be.

At the other end of the spectrum are the universities. It seems to me more thorough thought ought to be given to the kind of support the universities must have. We have so few people working in this field, in meteorology, for example, that we are going to be hard put to find first-class scientific talent.

I do not want to take too long in developing this.

In the university laboratories, the military, and industry, you must have first-class scientific talent. In these three areas the role of the

scientists is different. The university scientist trains men in absolutely pure research. The industry scientist works on developing problems, does research necessary there, and the scientist in the military does fundamental research which enables him to give first-class advice to the military.

There is one point I want to emphasize because without this it seems to me no program we have in the field of space, no matter how imaginative and how beautifully supported it is, can be successful.

In the past 10 years I have seen too many young men for whom we predicted great scientific careers picked off by industry, by laboratories other than industry, some of the nonprofit research laboratories, and lost, lost to those 5 or 10 years of dreaming, which produce people like Dr. Pickering, people like Dr. Whipple, and like Dr. Van Allen.

I know this, because I have watched them dream. We have lost them today. As far as I know, in spite of the impact of the first U. S. S. R. satellite, I, personally, have seen few signs of much having been done about it.

I shall be very happy to answer questions.

The CHAIRMAN. Doctor, do you see the need for some kind of agency on what might be outer space?

Dr. KAPLAN. Very definitely. I think that a single agency which will look over the entire program and which, I hope, will be in a position to consult with everybody in arriving at decisions is essential for this program.

In the IGY satellite program, the Department of Defense appointed the Naval Research Laboratory. The Office of Naval Research is manager for the program. They have gotten complete cooperation from the Army and from the Air Force.

You need a single-manager concept for anything that is complex, something that ranges from the problems of propulsion to the problems of, say, interpreting some experiment in outer space which has to do with magnetism or Einstein's theory of relativity.

The CHAIRMAN. Assuming we have a single management, whether we call him a director, administrator, or any other title, in the organizational setup as outlined in the bill which I introduced for the administration, what kind of man should be appointed to that position?

Dr. KAPLAN. I could name one very quickly.

The CHAIRMAN. What qualifications?

Dr. KAPLAN. I think the man who is presently Director of the National Advisory Committee for Aeronautics combines the entire range of qualifications.

The CHAIRMAN. What qualifications, is what I asked.

Dr. KAPLAN. He should be a first-class engineer or scientist. When I say engineer, I mean the sort of person that you associate with schools like MIT or Cal Tech. He should appreciate, of course, pure science. He should be a good manager.

He ought to be able to write the English language well, and be articulate enough and have range enough that he can talk at noon to the Rotary Club of Washington, the United States Chamber of Commerce, or the National Manufacturers Association, in the afternoon to the National Academy of Sciences, and in the evening be able to talk to his children and tell them what he did during the day; a man who has a wide range of understanding of the problems, a statesman, and a scientist.

The CHAIRMAN. Where can you find people with such a broad field?

Dr. Kaplan. You can develop a number of these men.

The CHAIRMAN. He must have a good personality, too?

Dr. KAPLAN. Yes, sir. I could name Dr. Lawrence M. Gould or Dr. Lee Du Bridge as men of that kind. I think there are a number of such men.

The CHAIRMAN. You have permission to edit and revise your remarks. Of course, you can elaborate or clarify them in any way you want to. Is there any consideration to the extension of the International Geophysical Year or period?

Dr. KAPLAN. In some of the areas of the IGY, the results have been so important and exciting to the scientists that both our National Academy of Sciences and the International Council of Scientific Unions have appointed special committees to continue this work after the IGY. This is in the fields of oceanographic and Antarctic research. Both international and Academy committees have been set up for the latter.

The IGY Committee has already recommended to the president of the National Academy the appointment of a continuing committee on rockets and satellites in the Academy, and we hope that a similar one will be appointed, worldwide.

I happen to be president of an association, international association, dealing with the upper atmosphere, and am now planning to set up a subcommittee on problems relating to the physics of space.

In many of the major areas of the IGY, results have been so stimulating that, in order to save time, planning by groups other than the United States National Committee for the IGY is now going on. This time both on the national and international side.

The CHAIRMAN. It does create a sort of healthy atmosphere, I imagine, for a discussion and exchange of views.

Dr. KAPLAN. Actually, the USNC–IGY is playing a sort of interim role in helping to carry over from the actual IGY. The result has been an extremely healthy international atmosphere.

The CHAIRMAN. Of course, there are many interesting questions involved. It involves sovereignty of the air; there is international law.

Dr. KAPLAN. We are aware that people have been thinking about it, but, so far as the IGY is concerned, no question has been raised in any of our relationships with other nations as to sovereignty or who owns space.

The CHAIRMAN. I understand that, but my question was that those intricate and interesting questions still exist?

Dr. KAPLAN. Yes. There are a number of very able people who are dealing with this question of who owns space. Dr. Cooper, at the Institute of Advanced Studies, in Princeton, an oldtimer in the field, a very eminent man in the field of aviation law, has done a lot of thinking in this area.

The CHAIRMAN. I understand he is going to appear before the committee.

Dr. KAPLAN. Yes.

The CHAIRMAN. This is a virgin field now that the world is entering into. No one knows, I suppose, where it is liable to end. There is a great unknown out of which will flow new discoveries. Would this be a good time for the nations of the world to try to establish plans

for peaceful exploration of the outer spaces before there is an intense, competitive race along military lines, or wait until later?

Dr. KAPLAN. I certainly feel strongly, or I would not have devoted so much energy to the IGY, regarding the importance of worldwide cooperation in matters dealing with our environment, whether it is space, the atmosphere, or the oceans, or the solid earth, because no one nation can get the data and information alone. You need international cooperation for the benefit of everyone. I think that the continuation of the pattern that the Geophysical Year has set would, indeed, be a fortunate thing for the world.

The CHAIRMAN. You may elaborate on that. I wish you would elaborate on your views as you edit your remarks.

Dr. KAPLAN. Naturally, because of my role in the Academy, and the International Geophysical Year, I have been thinking of all of the scientific aspects of this program.

Back of it is a strong feeling, which I try to present whenever there is a good audience to listen to it, that the finest defense of a nation is to have a stockpile of information about its physical environment, particularly at at time when its military technology is changing so rapidly.

In other words, I, for one, if practical, would take a large portion of money spent for defense and put it into pure research and be satisfied that I was helping to defend the Nation effectively in these rapidly changing times. My reason for saying that is that I have lived through active years of research in which I started the excitation or the production in the laboratory of one of the unknown features of the aurora borealis, the northern lights.

Thirty years ago, anyone who worked in that field was looked at as the purest of all scientists. Today, the northern lights determine the behavior of the high atmosphere; the descendants of the work I started 30 years later determine the safety of flight over polar routes or the safety of a nation.

In fact, I am on my way to San Francisco to speak to a large group there. The title of my talk is "From Spit to Sputniks," or the story of one spectrum line due to an atomic oxygen, from pure theory to combustion spectroscopy, to rockets.

What goes on in the high atmosphere, what are the winds at an elevation of 100 miles? The exploration of nebulae, our understanding of the sun's corona and even some of the current experiments in the field of the application of hydrogen fusion to peacetime efforts, are related to the kind of laboratory experiments, that I started some 30 years ago.

When you have lived through a period beginning with a highly academic excitation and production in the laboratory of the aurora which occurs in the northern regions at heights of 100 miles, or so and see it 30 years later as 1 of the key problems in which men of science are interested, then the point that Dr. Berkner made regarding the extention of our efforts to higher altitudes, and the finding of new things there, proves that no one can be extravagant enough to overstate the case for this program.

Also, man advances as he gets off the ground. He first learned to sail the seas, then he learned to move under the oceans, and he has learned to move higher and higher in the atmosphere.

25973—58——72

When I say that man advances, I am talking about the study of man himself, his spirit, his music and art as well as his science.

When you give him a new tool for looking at the universe, you are creating a new kind of man.

Incidentally, I am not an expert on the physics of space. I am just the person who tells them what they meet on the way out there. I think some of the people who are reporting now by the way, at the National Academy, are the most courageous scientists in our country, men who are accustomed to instrument rockets and satellites, having a year's work blow up in their faces, and then have the newspapers say that they failed, but then come back and do the impossible 2 months later.

The CHAIRMAN. Mr. Natcher

Mr. NATCHER. Dr. Kaplan, have you had a chance to go over the bill that is now pending before the committee?

Dr. KAPLAN. I went over it before I left for abroad and I went over it again last night. I am 7 hours behind schedule so I have been working since 3 o' clock this morning.

I personally think it is an excellent bill provided the people who carry out this function have the courage to recognize the fact that I tried to point out earlier, that first-class scientists at universities and military establishments are absolutely essential, if the money is going to be properly spent.

I have no quarrel with any proposals. I am not a manager.

Dr. Berkner is a more experienced manager. I am simply a teacher of physics, who teaches anybody from a Rotary Club member to an elementary student.

Mr. NATCHER. Dr. Kaplan, if you were in a position and had the right to select the Director of this new Space Agency, what type of individual would you select? Would he be a scientist or would he be a man successful in administrative duties, or what type of individual would you select for the director of this new National Aeronautics and Space Agency?

Dr. KAPLAN. I might say in answering this that I have had the personal experience now of heading one of the largest scientific efforts the Nation has ever made.

I could not have carried out my duties as chairman of the USNCIGY except for a remarkably devoted staff, particularly an executive director, Hugh Odishaw, who is a very good scientist, has engineering training, very articulate, knows the Government problems, and has good sense.

I think if you can get a first-class scientist and have in him the equivalent of an executive vice president of a company, who is a good, hard-boiled, sensitive character, a man of integrity, who knows how to manage his staff and yet has the stature to grow with the program, you have solved the problem.

Mr NATCHER. Dr. Kaplan, the Space Board provided under the bill is to consist of not exceeding 7 members. How does that number appeal to you? Is it large enough or too small, too many?

Dr. KAPLAN I do not think it is too many because as I recall the constitution of the Space Board, it represents people from many agencies who are interested and this requires a large board.

Mr. NATCHER As you know, Dr. Kaplan, in examining the bill it provides that 8 of the 17 members shall come from 8 different de-

partments of Government. That is on page 3 down at the bottom of the page.

Dr. KAPLAN. In this way it is similar in principle to the NACA.

Mr. NATCHER. Yes. That is correct.

Dr. KAPLAN. I think this has worked out very well, Mr. Natcher.

Mr. NATCHER. It also provides that at least one of the members shall be from the Department of Defense. In your opinion should each branch of the military service be recognized on this Board? Should there be one from the Department of the Army, the Navy, the Air Force, or would one from the Department of Defense be sufficient?

Dr. KAPLAN. I would really say that one from the Department of Defense probably would be enough. I feel from the experience that I have had with the IGY satellite program, that the existence in the Department of Defense of the special committee advising one person, Mr. Holaday, and carrying out the functions of monitoring the Vanguard and Explorer programs, has been very effective.

I am a member of that committee, by the way. In no part of my experience with the Vanguard or Explorer have I seen any reluctance or any difficulty on the part of any departments in cooperating with a single person in the Department of Defense.

I like the concept of someone from education and public affairs on the Board. The impact of the IGY satellite program on education alone, what it has done to the reexamination of education and so on, has been to me a worthwhile and a satisfying experience.

The increasing need for having a scientifically informed public in the United States means that somebody from education should be on a program that is as daring, far-sighted, and new as this program is.

Mr. NATCHER. Dr. Kaplan, from time to time we hear statements to the effect that here in this country we are not exchanging scientific knowledge with our allies. This gentleman sitting on my left is Mr. J. E. B. Hill, a member of the House of Commons of our ally, Great Britain; now, how do you feel about our exchanging scientific knowledge in this country with our allies as we should and, if we are, what accomplishments are we receiving?

Dr. KAPLAN. I could speak authoritatively only in the field in which I have helped to advise the Department of the Air Force. I have been a chairman and member of the Scientific Advisory Board's panel on geophysics for 11 years. The fact is that in the rocket program of the Air Force, the Army, and the Navy, in which we use high altitude rockets for probing the atmosphere, from the very beginning the military and this Nation released all the information.

In fact, until the rocket and satellite meeting at the Academy last October, which was followed by the announcement of the first Russian satellite, until that time, so far as I know, we were the only nation that had used rockets for upper atmospheric soundings and published all the information freely.

The result of that was that theoretical physicists and geophysicists, particularly in England, Drs. Bates and Massey, Dr. Nicohlan, Belgium, the present secretary-general in the IGY, dozens of men, men from our allies and men on the other side of the Iron Curtain, were able to take this data and analyze it. We were relatively new and weak in the theory and they were strong, and the net result is that our rocket program improved and today we are doing things with

rockets in the Antarctic and at Fort Churchill that even I, with not a fettered imagination, would have thought impossible a number of years ago.

We are literally firing a chemical analyst up there in the form of a mass spectrometer—sucking the air and determining its composition while the rocket goes up, turns around, and comes down.

We could not know this information unless the information were freely published.

On the other hand, I think in the world as it is today I think judgment has to be exercised on these matters and this is a very difficult problem. In the case of the country that you mentioned, Great Britain, I told our distinguished guest today that I like to stop in London just to be able to read the Manchester Guardian and the London Times I like England and our ties with British science are particularly close in this area

The British are now firing rockets of their own in Australia at the Woomera range, for the IGY.

I should certainly think that in as many areas as possible free exchange among nations benefits us.

Mr. NATCHER Thank you, Dr. Kaplan.

The CHAIRMAN. Doctor, on page 6 of the bill, on line 3, it states: "Arrange for participation by the scientific community in planning," and so forth.

What is your opinion as to the interpretation of the words "scientific community"? More directly, is it confined to the United States, or worldwide?

Dr. KAPLAN. I would like again to use the Geophysical Year as an example, because it is current and I think it is well known.

In the Geophysical Year, in introducing a group this morning to report on preliminary results of Explorer No. 1, our first satellite, they are talking right now—I emphasize preliminary results—I pointed out in introducing the Chairman that the five speakers came from the California Institute of Technology on the Pacific coast; the State University of Iowa, the Geophysics Research Directorate of the Air Force up in Cambridge; the Naval Research Laboratory down the road here, and then at Harvard, the Smithsonian Astrophysical Laboratory; industry's Dr. Porter, the Chairman coming from GE; this industry, university, Government laboratories—the whole country represented.

I think that the National Academy of Sciences will take the responsibility for continuing its advice to the Nation in this area as it has taken the responsibility for administering and directing the IGY and it certainly represents the entire scientific community.

If this new Space Agency goes to the Academy for this advice, then there should be no difficulty in working with the scientific community.

Secondly, where the talent exists among scientists of other nations, and here I think it is natural that we deal necessarily with scientists of nations with whom we have been associated for a long time, we should include them as part of the concept of "scientific community."

The CHAIRMAN. You would interpret that as being on the world level?

Dr. KAPLAN I would interpret it as being on the world level, but practically, from the point of view of our own Nation and its advancement in these very difficult times, as being primarily on our own

national level, with the extension to the rest of the world as the situation develops.

Mr. NATCHER (presiding). Mr. Fulton.

Mr. FULTON. I want to welcome you here as one of the distinguished scientists, not only of the United States, but the Western World, and the whole world.

We are proud of you and we hope your contributions to this subject on basic research and physics will continue.

We Americans are very lucky to have had pioneers against a cold public opinion rather than an adverse public opinion. They have persevered just as they always have through the years and now these activities of you and other scientists are coming to fruition and Congress has taken recognition.

I explain and apologize to you for the 8-hour delay which you had, partly caused by the weather and partly by a misunderstanding at the Washington Airport.

Dr. KAPLAN. I appreciate that, Mr. Fulton, but I think even an atmospheric physicist occasionally can stand a reminder of what the problems are. I must say this was a very drastic reminder.

Mr. FULTON. The weather predictions we need and we hope some day to have the satellites which you people send up which will give us the kind of weather that all the Congressmen will vote for.

I know the two inspectors down at the Washington Airport do a very excellent job. We Congressmen go in and out a lot and we have gotten every courtesy.

As a matter of fact, I called Mr. Swing's office this morning and had Joe Waters, legislative counsel, come over here especially and give you a written explanation of how the thing occurred at the airport. So that is available to you on a personal basis, if you like.

Now, we have with us a distinguished visitor whom I would like to introduce with the permission of the chairman.

Mr. J. E. B. Hill of the British House of Commons is with us. He is a Conservative member of Parliament, representing South Norfolk. He is sitting on the Democratic side.

Mr. NATCHER. If the gentleman will yield—which is the proper side, I believe.

Mr. FULTON. The gentleman, Mr. Hill, says he usually sits on the right in the House of Commons. He is a graduate of Merton College in Oxford and is a barrister and farmer by background.

He was elected to Parliament in the bielection in 1955, and is one of the few people of an official capacity from a free government in the Western World who has visited Communist China. He was there in 1956.

Mr. FELDMAN. Congressman, do you think it is a rare thing to have a conservative Democrat?

Mr. FULTON. I am very glad to know that the Democratic Party and the Republican Party have room in them for both conservatives and liberals and that by a certain uniting of the minds they do get the programs through.

Now, I put in the record the background of Mr. Hill and welcome him to the committee.

Now, Dr. Kaplan, we are coming to the end of the International Geophysical Year, the problem comes up: How shall we continue the programs that we have initiated and that are interesting, not only to

the United States but the world, which we in Congress now believe should be proceeded with promptly?

For example, our United States Vanguard program, because it has been a program under the International Geophysical Year, will probably automatically expire without further congressional authorization.

What should we do? Renew the International Geophysical Year, try to reinstate it when the nations have decided they are probably not going along with it, or should we just start individually on a national United States space policy and then try to get international cooperation?

Dr. KAPLAN. There are international scientific unions as you know. Dr. Berkner is the president of the International Council of Scientific Unions. In these international unions, such as the one I am associated with, the Union of Geodesy and Geophysics, of the International Astronomical Union, there are provisions for continuing international cooperation and they will inherit, in my opinion, and should inherit, a great deal of the planning and thinking and the followup that should follow the International Geophysical Year.

We should as a nation, I think, do our part in those areas in which our cooperation is required.

For example, in rocketry and the use of rockets or satellites, or in oceanography. The ocean covers 75 percent of the earth, to give you an example, intimately connected with the weather, with the food resources of the world.

It is to our benefit to cooperate with the other nations and to continue to learn about the oceans whether in the area of purely peaceful knowledge of the oceans, or the part of it having to do with our defense.

Now, there are mechanisms, following the example set by the IGY, through which the National Academy can appoint a committee, in any field. These committees can go to the Congress through the National Science Foundation just exactly as we did in the IGY, and make sure that American science in its broadest context, industry, Government laboratories, et cetera, can take part.

I think the pattern is set and should be followed. It would be most unfortunate if this pattern should be short cut.

Mr. FULTON. That brings up a question. If we in Congress establish a new Agency that will be called in effect the National Space Agency, to have the primary jurisdiction and set the policy on space, both astronautics as well as aeronautics, should we then on this Space Agency have a setup so that the international aspects of the problem can be dealt with through that mechanism?

Dr. KAPLAN. I think it is very important that the Space Agency have a setup so that they will consult the Academy which represents the national and international bodies. I think it would be a bad step if we did not.

We have set, it seems to me, a remarkable example of international cooperation already and I think from any point of view, the purely hard-boiled scientific point of view, or any point of view you can look at, it seems to me that a good, decent, imaginative international attitude of this Nation will in the long run redound to its benefit.

The Academy is organized to help achieve this.

Mr. FULTON. You feel that the International Geophysical Year participation of the various agencies of the United States has been

worthwhile, first, and, secondly, that we should continue by some means an expanded international program on space matters through various United States agencies?

Dr. KAPLAN. I would agree with that. I think it is very well stated if I may say so. It is clear.

Mr. FULTON. May we ask you, too, Dr. Kaplan, your judgment on the effect of the IGY? Has that been to open up a whole new area of thinking in the world? That means before and behind the Iron Curtain. And has it also been a stimulant to the scientists of the world to cooperate on the exchange of basic information for the future progress of the world?

Dr. KAPLAN. I can give broad examples and special examples. Perhaps the most dramatic special example is the Weather Bureau in the Antarctic in which the 12 or 13 nations, including the U. S. S. R., participate. There is a Russian scientist there. One of our scientists is at their base. The United States Weather Bureau operates a Weather Central for the United States National Committee in the IGY and in turn for the rest of the world and it is the first time in history that two daily weather maps are issued for 6 million square miles with average high-altitude soundings last season up to around 65,000 feet.

The value of that no one will know until the analysis of the research phase of the IGY comes and we are now planning in order to make certain that such analysis and research does not lag.

Eventually you have to start thinking and planning. My own hunch is that the impact of the Antarctic cooperation will be so great that the nations of the world will want to continue this just from the point of view of weather alone.

Mr. FULTON. As we have a member of the British Parliament here, we might discuss our relations shortly with the Government of Great Britain in this field.

We in the United States are setting up a committee in each House, one in the Senate, one in the House of Representatives, to handle space matters from the legislative point of view, and so far have been aiming at the establishment of a civilian space agency.

Do you think that we in the Western World, and especially between the Governments of Great Britain and the United States, should have a closer liaison on these matters and second, because between Britain and the United States we do not have enough scientists to do the job or compete successfully at this point, that we should avoid duplication and share our joint scientific assets and resources?

Dr. KAPLAN. That is a difficult question. My own personal feeling would be yes, because of the close relationship between the two nations.

On the other hand, in the whole pattern of the IGY there have been many relationships between two nations, bilateral relationships. They have established it themselves.

In these terms your suggestion would be entirely fitting.

I do not think that the relationship should be just with one nation, but there are many natural reasons for bilateral agreements.

Mr. FULTON. Actually, your position and mine is that there should be a broad base of general knowledge which we give to the world from the United States and cooperate completely with the world. My

question refers probably to the missile programs and rocket programs that could be both for peaceful and military uses.

In those particular programs, I am sure there is no use of Britain shooting up and trying to make the same kind of rockets we already have.

Dr. KAPLAN. Actually, in the IGY, the cooperative effort in the rocket field was such that when the British, particularly the Japanese, decided to try a rocket program, we invited the Japanese scientists to visit us. We cleared it with the Government, the Naval Research Laboratory, Signal Corps, Air Force; they were extremely hospitable.

As a result, the Japanese have contributed to the rocket program. We have had the same relationships previously with the British, but entirely in the area of instrumentation of the rockets.

To the scientist, the propulsion of the rocket is a matter of importance, of course, but not a matter related to science.

For instance, if I want to go down to the Antarctic to make observations of the aurora there, I am not at all concerned about the icebreakers or their techniques or the ships that take me down or the airplanes. I just want to get down there.

On the other hand, it is not quite that way in the rocket field. It is necessary to cooperate closely with the men who design it so that your instrumentation can withstand shock and acceleration and things of that sort, and there has been close cooperation.

There is a beautiful example, by the way, at Fort Churchill where the Canadians and the United States jointly operate one of the most remarkable rocket-launching facilities, I think, in the history of the world, in that Arctic desert waste. Some of our most successful high-altitude soundings have been carried out there.

The cooperation of the Canadians is really generous.

Dr. Davies is an old friend of mine who showed me around when I went over there to help dedicate the facility with General Gavin. I asked Davies, "Have you left any space for the Canadians?"

To the extent to which it is possible, I would say the closer the cooperation, the more money you save and the more likely it is that you will get the answers.

Mr. FULTON. That is good news for our taxpayers.

Dr. KAPLAN. I would think for the IGY it has been fortunate, but in space physics, space explorations are an extension of it; we are in the position that the pure scientist in the best sense of the word is also a practical man. Weather is a challenging problem. Oceanography is a challenging theoretical problem that defies solution. Yet men's lives and their economy depend on it.

So we are in a very fortunate stage there. We do not have to justify the practical values of the geophysics.

Mr. FULTON. May I say to the good doctor that you can edit your remarks or change them as you wish in the testimony because we want the testimony to be your considered judgment, not your offhand opinions.

Secondly, would you make a statement for the record for us later, with the chairman's permission, that will include our participation and that of Soviet Russia in the IGY? Give us a short history of the relationships and how it worked out?

Mr. NATCHER. Mr. Fulton, as I understand, you want Dr. Kaplan's statement to be short, in other words, a brief statement, for the record. Without objection, it is so ordered.

Dr. KAPLAN. If it is agreeable with the committee, Dr. Sheldon, I am quite sure, can get in touch with Mr. Odishaw and he will be very happy to edit, since I will be out of town.

Mr. FULTON. Likewise I would like a summation from you in outline of the accomplishments that you think the IGY has made, particularly in reference to the United States. as well as to the world at large.

But if you would relate that to our own country particularly, I think it would help us from the Congress' point of view.

(The material referred to follows:)

SUPPLEMENT TO TESTIMONY OF DR. JOSEPH KAPLAN, CHAIRMAN OF THE USNC-IGY, BEFORE THE HOUSE COMMITTEE ON ASTRONAUTICS AND SPACE EXPLORATION, SUBMITTED AT THE REQUEST OF MR. FULTON

It is of course very much too early to assess the accomplishments of the International Geophysical Year. Such an assessment can properly be made only after all the data which is even now being obtained has come in and then only after the scientific community has had an opportunity to digest and redigest the data.

However, even within the first few months of the IGY program it became apparent that this highly intensive effort was reaping preliminary results beyond our fondest expectations. Successful technical innovations, as well as actual findings, began to come in in some quantity. Some of these were based upon IGY work that had been performed in the months prior to the formal opening of the program. Much of it came in the next few months. I should emphasize that in both cases the results I am talking about are entirely preliminary. They are the kind of thing that one grasps even before full analysis of data. When these data are fully analyzed, it may be that some of these preliminary findings will be modified or enlarged.

I believe that a good picture of these early accomplishments can be obtained from the attached report from the January 17, 1958, issue of Science, the publication of the American Association for the Advancement of Science. The report was prepared by Hugh Odishaw, Executive Director of the USNC-IGY. It summarizes findings reported by the institutions and scientists participating in the IGY during the first 5 months, principally in the United States program, although there are repeated references to projects conducted in close cooperation with the national committees on other countries.

Since the publication of this report we have had indications of continued results in the same pattern. Then of course there are the very dramatic results reported on the very day of my testimony before this committee by those scientists who prepared the experiments for 1958 Alpha, the first US-IGY satellite. Among those findings were the very exciting results obtained by Dr. James A. Van Allen of the State University of Iowa who is Chairman of the IGY's Working Group on Satellite Instrumentation and who prepared the cosmic ray experiment carried in 1958 Alpha. Van Allen's findings, again preliminary, indicate that there is a hitherto unsuspected belt of solar radiation, a thousand times more intense than was expected, lying in a region about 600 miles above the earth. This is a highly important factor which will have to be considered in future space work.

Dr. KAPLAN. We are actually doing it in the satellite field this morning at the Academy. I will be back next week and will personally read the testimony.

Mr. FULTON. Let me just finish with this.

You do favor the creation of a new space agency to have primary jurisdiction to set a national policy for space. If necessary, to have a new agency?

Dr. KAPLAN. I would think that, in view of the tremendously complicated, rapidly changing picture, that I have seen in the past, which has occurred only in the last year, and many other factors, and I think in view of the success that the NACA as an example, has had, I think the creation of a new agency which is essentially a very great extension of the NACA, is a wise move. Again, however, with

the proviso that we have already discussed, that all the talents of science be used most economically with the view of using scientists well and not letting our good young men waste their talents.

Mr. FULTON. You firmly recommend this be a civilian rather than a military agency; is that correct, and not be subject to the policies of the Department of Defense in effect?

Dr. KAPLAN. Yes. I think if I were a propagandist from the Department of Defense and had their welfare in mind, I would feel very strongly about having it a civilian agency.

I think that most of my friends in the Air Force, Navy, and Army, particularly the Air Force, with which I am closely associated, feel this way. They have excellent records in the way they have used civilian agencies or civilians for research. I think they, too, should welcome this approach as being the most effective by which their problems will be solved.

Mr. FULTON. Thank you very much, and you have made an excellent witness.

Mr. NATCHER. Mr. FORD

Mr. FORD. Dr. Kaplan, I notice that you are United States Chairman of the National Committee for the International Geophysical Year. It that an appointment by some person, or agency of the Government, or is that from the scientific community itself?

Dr. KAPLAN. This is not too often understood, but the organization in the United States, or the entity which is responsible for United States participation in international scientific affairs, is the National Academy of Sciences, and when the International Council of Scientific Unions decided to sponsor the IGY, they went to the academies of all the nations for help. In Great Britain, for instance, they have the Royal Society in London which is the analogous organization. It is private, it has a charter, it is charged with advising the Govern-in scientific affairs.

The Academy appointed a committee. My well known ability to travel and to suffer the vicissitudes of such things as I did the other day and still come up smiling, I am pretty sure was the principal basis for my selection as chairman.

Presumably science had something to do with it. I accepted the chairmanship 5 years ago and in view of the tremendously exciting developments that have occurred in spite of the vicissitudes of the job, I haven't regretted it.

It has been an historical 5 years for the Academy and I am sure for the Nation.

Mr. FORD. We had a witness a week or so ago who was asked the question whether or not we should extend almost immediately the International Geophysical Year. As I recall the testimony, the recommendation was that maybe we ought to have a period of time lapse in order that the scientific data collected can be properly evaluated before inaugurating another IGY, this being the third one.

What is your comment on that?

Dr. KAPLAN. I would certainly agree that we need a period of time for analysis and research and for the development of men who have gotten interested in this field. The way science progresses is that bright young men go in the most exciting directions.

If it turns out that the data of the IGY, say in meteorology, oceanography, gladiology, all of which are related—they deal with heat, water,

and ice—if that gets exciting for some smart young theoretical physicist or chemist, I think that is where they will go. I think we have enough data to have excited these people.

In the meantime, we cannot afford to neglect or to allow a hiatus in the stress of those areas which we have developed and are staring us in the face. We get new information on the structure of the earth, the amount of ice, its depth, its distribution, and if it is important for the scientists to have that information, we should not arbitrarily wait for another sunspot maximum.

I think it is a matter of judgment. The spirit of the IGY, the spirit of the international cooperation, and the advantage of having nations work together, I think is going to carry over into other fields so that this will stay with us.

I do not like the word, but if we have a breakthrough somewhere, we certainly will not wait for the sun to come around and act up again to go through this business.

May I add one more point.

The impact of man's physical environment on his technology, on his way of life, is increasing almost exponentially. You could live with the weather a few years ago much better than you can now.

Because of high speed of flight, the character of most of our operations, a knowledge of our physical environment is far more significant and, consequently, we cannot neglect it. We cannot wait for another IGY to find out whether you can safely dump atomic wastes in the ocean and hope you will learn about circulation sometime in the future.

In the meantime, you may be destroying the food for future generations.

These are areas in which I think we have to have good judgment and the best judgment—this is why I like the structure of your Advisory Board—the best judgment in my opinion is all the people in the United States, as many as possible.

If you have a representative board, they are literate and they are knowledgeable, I would like it better than to have a board consisting of nothing but specialists.

Mr. FORD. In other words, you would prefer a board of 17 or a reasonable number as an advisory group in preference to a set commission type of 5 members or 7 members on a full-time basis?

Dr. KAPLAN. I think in view of the broad character of this area, yes.

In this particular area I would prefer the board type of operation as presented in the bill.

I might say in saying this I do not want to imply any adverse comment on the AEC. It is completely outside my area of competence.

I think I like it because I am very sensitive to the way in which the IGY has affected thinking of children. I have experienced a half dozen cases where people have asked for my autograph. Now, coming from California, that is a striking example. These children are excited.

I think the public has a right to be in on science and understand what is possible and we get good advice from men who come from areas other than the restricted areas of science.

Mr. FORD. Doctor, I know for some years you have acted in an advisory or in a consultant capacity with the various departments, the various constituent departments of the Department of Defense.

Has that been on a contract basis through the university, or has it been on a per diem basis?

Dr. KAPLAN. It has been on a per diem basis on a personal contract. On occasion there have been cases where there were special studies during the summer. I think most of the members of the Scientific Advisory Board who come from private life, as I do, and from the universities, are on this contract with ARDC.

Mr. FORD. I ask that because in the legislation there is a provision which says:

To obtain services as authorized by section 15 of the act of August 2, 1946, at rates not to exceed $100 per diem.

We have had in the past on the floor of the House and in committees, discussions whether $50, $75, of $100 per diem is adequate.

Would you care to comment on that?

Dr. KAPLAN. I first came on the SAB with Dr. von Karman as chairman. He is still the best aeronautical scientist in the world. I considered it a great distinction to be associated with that group. At that time we had nothing except the relatively inadequate per diem of $10, or $6 a day. Even then you could not stay in Washington at some of the hotels which I will not mention, for that sum, but I found this was part of my job.

I was a university professor. If I wanted to make money I would not have gone into the university. I do not know what they meant by it, but recently when I spoke to the National Association of Manufacturers, a trade journal referred to me as the best salesman they had ever heard. I hope they meant it well.

One does not do this for money. When the $50 a day business came in it was good.

In my own case, and I suppose it is true in other cases, I have avoided ever allowing myself to be used as a consultant by any private organization. I am in the area of great industrial activity in this field. I have done it with full awareness that I could resign from the SAB, but I like the Air Force; it is young, vigorous—it operates increasingly in the media in which I do my science. They have been very cooperative. They do not always do what I tell them, but what I tell them is not always right.

Consequently, I have been happy in my Air Force association, but I do not think from a cold-blooded business point of view the fee of $50 a day is a realistic fee from what I hear. I have not experienced these other fees and do not intend to while I am still on the SAB.

On the other hand, there is such a thing, particularly in these difficult times, as pride of country; we are citizens first, scientists next.

I have not found it any disadvantage to have been a college professor and adviser to the Air Force at this relatively small per diem. I have found the work exciting, the Air Force receptive.

I think General Keirn will testify that they like me.

Mr. FORD The amount should be adequate, but it really is not the incentive that makes talented people come and do the job.

Dr. KAPLAN. Frankly, you cannot buy the services of these people. You should not have to, it seems to me, in a case where it is for the welfare of the Nation.

Now, when I was asked recently to appear on a television program, and I want to go on the record on this, the assumption was that being

a college professor I would appear for nothing. This was a sponsored program. First of all, I would not appear on a sponsored program, generally, because of my position with the Academy.

Secondly, I simply asked them "What do you pay your most highly paid comedian and that is the fee for which I will appear," because I thought I was reasonably enough conceited that I was just as good as a teacher of scientists as some comedian was a comedian.

Naturally, they did not employ me.

But that is a sore point with me.

Mr. NATCHER. Mr. Feldman.

Mr. FELDMAN. Doctor, what are the possible scientific advantages and practical consequences of an adequate space program?

Dr. KAPLAN. The answer to a question like that, I think, depends on the scientific experience of the person. I would rather answer it from my own experience.

As I look at the history of astronomy and its impact on our technology, and earlier I mentioned a relatively minor aspect of it in the study of the aurora, but when one looks at the history of astronomy, it was the attempt to understand the source of energy of the sun that led to the development of the theory of hydrogen fusion that would eventually, I hope, lead the world to the development of its greatest single source of energy.

Now, what will happen in the biological sciences when life is studied in new environments, I don't know, but my guess would be that equally exciting results may very well come out.

Mr. FELDMAN. What role should scientists in the Department of Defense play in this space program?

Dr. KAPLAN. I enlarged on that point a little earlier. The emphasis again, I think, I will put on the role of the young scientist that is working on his doctorate, who wants to develop into a scientist on his own and wants to determine his own way of life and so on, his own areas, and I would say in this particular program that these young scientists should be adequately supported and given a real opportunity to work.

Now, they will be associated with the more experienced people like Dr. Van Allen, Dr. Whipple, and others who are now working in this field and I think they can contribute a great deal. Every possible help can be given to these men because they work and think in probably the best environment of scientific thinking we can have.

Mr. FELDMAN. During the course of these hearings, Doctor, it has been stressed time and time again that the need for training new scientists is uppermost and most important. In that connection what is being done to establish what I would call a seed crop from which other scientists could be developed.

In other words, it seems to me that when the universities train extremely able young scientists, that those scientists could in turn train a number of other scientists and in that way we build up a great scientific force.

Now, if the Government and industry recruit what I call the seed crop and they are not in a position where they can in turn teach others, then we are plowing under the seed crop.

How would you go about developing a program which would insure us of a large force, if you want to put it that way, of scientists?

Dr. KAPLAN. In the field of rocketry, it started out that first-class work and development of good young people has occurred both in the Defense Department laboratories and in the universities, with some exception perhaps in industry. This has been a rather exceptional phenomenon. I think one puts it a little strongly, and perhaps I did it also, that industry plows these men under, because there are known exceptions. Men in industry have won the Nobel prizes, the transistor was developed by the people at the Bell Telephone Laboratories. These are notable, but exceptions. In general I think scientists in industry would be the first to admit that the universities are the best way to develop good young scientists because that is exactly where they go to get their people.

I think it is shortsighted when a first-class young man is allowed to go into industry before he has a chance to teach, to do research and to show whether or not he is going to be one of the real scientific leaders of the future.

I think the solution to it is pretty practical. Pay him a reasonable amount. Don't ask a young man with 2 or 3 children not to be able to have 2 or 3 more or to live on an economic basis where he is worried at the end of every week whether or not the budget will balance.

But give him a reasonable chance at peace of mind which you need to dream and think, as increasingly is being done.

I frankly do not think that anyone in the country as yet has been sufficiently imaginative in this area. I do not speak for myself because I am one of the oldtimers. I speak for the good youngsters.

Mr. FELDMAN. I was thinking more in terms of training one good scientist in this field, who was able to impart his knowledge to others, that they, in turn, could train 4 or 8 more and those 4 or 8 more might be able in turn to train 4 and 8 more each, and so on.

In that way in a relatively short period we should be able to build up our scientific background.

Dr. KAPLAN. We are doing something in that area. The National Science Foundation's scholarship program helps. But we are not, in my opinion, strong enough and imaginative enough and courageous enough in this area. It is not a very expensive item.

Of course, commenting on the high schools, there I think we simply have not faced the problem at all. There has been a lot of talk, a lot of discussion, lots of opinions, but I have not seen any school district as yet that I know of that has taken the kind of action which will attract first-class people to high school teaching.

There has been a lot of talk about doing things in this field and I guess there has been some action. I think basically it starts with making it attractive enough by rewarding those with special knowledge by special compensation.

The very men who criticize our high-school system are men who do not recommend that their best students teach in high schools. This is unfortunate. They cannot really do it. There is no opportunity in high school to develop into a first-rate scientist.

With some of the tremendous, perhaps necessary, bureaucratic control of curriculum makers, et cetera, it is probably pretty difficult to develop into a first-class teacher in some high schools.

How can you develop into a great teacher under circumstances where you have no room even to experiment with your teaching,

let alone have a little bit of equipment or opportunity to get in touch with nature, itself?

Mr. FELDMAN. Is there anything being done to correct that?

Dr. KAPLAN. There are a lot of meetings going on and a good portion of my time goes to talking to teachers and to school students and curriculum makers and so on. They are thinking, they are worrying about it.

I think the impact of the U. S. S. R. satellite on subsequent thinking has created an atmosphere of at least healthy concern. I understand there are many bills before the Congress. How basic they are, I cannot say except that I have the feeling that they are not as courageous and as basic as they should be.

Mr. FELDMAN. Is not the interest subsiding in direct ratio to the fact that the sputnik is no longer in the air and there does not seem to be one, at least there has not been any talk of one, in the immediate future that will be as sensational as the two others that did go up?

Dr. KAPLAN. I am sorry; I did not hear the question.

Mr. FELDMAN. In other words, the interest seems to be subsiding now because of the fact that the Russians have not done anything sensational in recent months.

Dr. KAPLAN. I think it is more basic than that. I think it is a very difficult thing in these days of sciences that are essentially removed or esoteric for even intelligent laymen to understand science.

Very few scientists have the skill, have developed this skill to make the layman understand them. There are increasing numbers of television programs, and I think they have done a fair job of reaching the public, but it is very difficult to reach them with these basic facts, the simple facts, the fact that when a man drops a magnet into a coil of wire a galvanometer deflects and that this led to the development of new industry and a profound change in our way of life.

You have to tell them that story again and again.

Out of a thousand scientists who will be leaving this week after the meetings in Washington, not many are able to tell this story. They have not had the training. They are beginning to get it. They are beginning to respect the man who can tell this story.

Up to now the men who commanded the respect were the research men, occasionally a really great teacher.

But the popularizer of science who has to create a great articulate; literate public, was not receiving the Nobel prizes; was not receiving the acclaim. He is getting it now. Until we get it only the very sensational things will attract attention.

We are in a period, I think, of evolving into a nation of really intelligent people. I am glad that IGY and sputnik had something to do with it.

Mr. FELDMAN. How did the IGY arrive at the decision to recommend the earth satellites?

Dr. KAPLAN. It was really a simple idea. We had included rocket programs for the study of high atmosphere. A rocket, you know, goes up, turns around and comes down after spending a few minutes in the high atmosphere. Rocket soundings are difficult; it is restricted to 1 region or 1 station.

You do not see the whole world or even a reasonable part of it. When a few scientists at one of the international meetings got together and decided that the art of propulsion had come to the point

where we could reasonably ask our Government for support of an extension of our rocket program, to put up a satellite, what I referred to earlier as the long playing rocket, the LPR, to use a somewhat well-known expression, we decided to recommend this because we envisaged such simple things as a solar flare disturbing communication and instead of doing what we have done in the IGY, sending a rocket up and have it turn around and come back and give us one piece of information, we could have the satellite up there during the solar flare, observing it, for the first time giving us the history of a solar flare as it developed and as it subsided. We were naturally excited.

On the other hand, we wanted to be reasonable. We were not concerned with what any other nation was doing. We felt that as one of the great nations capable of doing it we owed it to the period of history and ourselves to do it.

We made the recommendation. The history of it is now quite well known history. It was accepted. The Congress wisely supported us. The military establishments supported us.

In my opinion the program and its scientific concepts has been an eminently successful program in spite of the fact that I have seen no headlines to that effect as yet.

Mr. FELDMAN. I think it has been generally accepted as one of the great achievements

Are there any IGY results to date that emphasize the wisdom of this decision?

Dr. KAPLAN. I am familiar with all of the results that are coming in. The fact that we have gotten up there and the possibility that now exists of extending the solar flare studies is really exciting. In 1 or 2 of our rockets fired during solar flares, by coordination between the solar astronomers and the rocket people, with the astronomers warning them in time so they could get the rocket up, we for the first time understood what kind of radiation from the sun caused ionospheric disturbances and radio blackouts, which are very serious practical problems.

The fact that we will be able to extend this by means of a satellite I have already referred to as really exciting.

Mr. FELDMAN. What continuing role should the academy play in this program?

Dr. KAPLAN. I think the Academy represents perhaps the most objective scientific agency in the Nation. They have no particular interest except to advise the Nation.

There has already been carried out what I thought was a very excellent summer study for the Air Force, they have done some work for the Navy, there are a tremendously increasing number of areas in which they are called on.

I think the Academy is one place where all of American science and thought related to a given technical and scientific field can be focused. This is its role.

It should be there to be called on by the new space agency or by anybody else.

I am sure Dr. Bronk will agree that the future of the Academy will be an increasing use by governmental agencies of the Academy in its advisory capacity, and in terms even of its capacity to operate. But in this case I think advice is essentially what it should give.

Mr. FELDMAN. I have no further questions.

Mr. NATCHER. Dr. Kaplan, we want to thank you for the fine statement you have made to our committee and on behalf of our chairman, Mr. McCormack, and the other members of the committee, I want you to know that we appreciate your appearance.

Dr. KAPLAN. Thank you. It is always a pleasure to appear before a congressional committee.

Mr. NATCHER. Our next witness is Major General Keirn.

Will you come around, please, General Keirn. We are delighted to have you with us at this time.

As I understand, you are the Assistant Deputy Chief of Staff for Nuclear Systems of the United States Air Force, and the Atomic Energy Commission.

General, do you have a prepared statement?

STATEMENT OF MAJ. GEN. D. J. KEIRN,[32] CHIEF, JOINT AEC-USAF OFFICE FOR AIR, NUCLEAR PROPULSION

General KEIRN. I do, Mr. Chairman.

Let me get my titles straight. I am the Assistant Deputy Chief of Staff for Development, Headquarters, United States Air Force. The Deputy Chief of Staff for Development of Nuclear Systems. I am General Putt's assistant for nuclear systems.

In addition I do have a second hat. I am Chief of the Aircraft Reactor Branch in the Division of Reactor Development of the Atomic Energy Commission.

Mr. NATCHER. Fine, General; we are delighted to have you with us. You may proceed according to your wishes.

General KEIRN. Thank you.

I would like to read my statement, Mr. Chairman, if I may.

Mr. NATCHER. You certainly may, General. Go right ahead.

General KEIRN Mr. Chairman and members of the committee, I am happy and honored that this committee has asked me to testify on this most important subject. I am confident that through these congressional hearings will come the legislative actions that will provide the means to insure United States leadership in space and space technology.

Before going into some of the unclassified details of programs for which I have responsibility, I wish to take note that you were given a great deal of information by Gen. D. L. Putt, Deputy Chief of Staff for Development, Headquarters, United States Air Force, on:

1. Reasons why our country should undertake a national space program;
2. Logical agencies to manage and implement our national space program;
3. Space exploration tasks we must emphasize.

[32] Keirn, Donald John, air force officer, b Elbert, Colo, Feb 24, 1905; s John Augustus and Clara May (Rood) K B. S, U S Mil Acad, 1929, M S, in Aero Engring, U. Mich, 1938, student Nat War Coll 1950; m Martha Jean Kennon, Nov. 27, 1936, 1 dau, Margaret (Mrs James Francis Hilleary) Commd, 2d lt USAC, 1929, advanced through grades to maj gen, 1955; AC mem Durand Jet Propulsion Com, 1941, spl assignment jet propulsion, United Kingdom, 1941, chief research br Power Plant Lab, Wright Field, 1942–44, chief Power Plant Lab, 1944–46, liaison officer Manhattan Engring Dist, 1946; project officer nuclear energy for propulsion of aircraft (NEPA), 1946-50; spl asst. to dir div. mil. application AEC, 1947-50, chief aircraft reactors br, 1952——, dep chief staff for research Air Research and Development Command, 1950; comdg. gen 1009th Spl. Weapons Squadron, Washington, 1951, chief Office Aircraft Nuclear Propulsion USAF, 1953-57, asst dep chief of staff for development, Nuclear Systems, 1957——. Decorated Order Brit. Empire, recipient Thurman H Bane award for aero work jet propulsion, 1944. Mem. Inst. Aero. Scis. Presbyn. Home 4255 35th St S, Arlington, Va Office, Nuclear Systems, Hdqrs, USAF, Washington 25.

I, too, believe that we are on the threshold of the space age. Accordingly, we must make aggressive plans and be aggressive in their execution so that we will, at an early date, reap the benefits of space exploration.

As with any bold plans to conquer the unknown, I want to caution that there will be disappointments, even failures. Such failures have not been uncommon during the course of our past ventures into the regimes of supersonic speed and high-altitude research.

Accordingly, while I feel our space exploration program should be bold in concept and plan, it should be deliberate in approach. Our enthusiasm must be tempered with commonsense, and use to the fullest our scientific ingenuity and those elements of our background which have permitted our probing of the outer atmosphere to date.

We must not be subject to decision by emotion. To be really clever requires time.

Our space program and its results must have the respect and admiration of the American people and the peoples of the free world. The guidance of, and the responsibilities delegated by the Congress can insure these objectives.

I feel that our immediate space exploration goals should be confined to the nearest planets of our solar system; Mars and Venus, and, of course, our moon. The mean distances to these near planets are extremely large: To Mars, about 50 million miles; to Venus about 25 million miles; while it is only 240,000 miles to the moon.

I call your attention to the relative nearness of the moon. Assuming straight line travel and an average speed of 25,000 miles per hour, it would require about 83 and 41 days, respectively, to reach these planets, but less than half a day to reach the moon.

If we consider the far planets, Neptune, 2,700 million miles, and Pluto, 3,600 million miles, we find that an average speed of 25,000 miles per hour, the trip would require 12 to 18 years, respectively, 1 way.

This becomes a significant portion of man's life span, and obviously, considerable advances in propulsion must be made before such trips are contemplated.

The partial applications of space flight about which we speak today, such as mapping, weather forecasting, and communications, will, in all probability, be accomplished from orbits in space between the earth and our moon.

To perform these tasks with greatest efficiency, however, will undoubtedly require manned vehicles.

We can gather much basic information by steps that have been taken by the Advanced Research Projects Agency and the Air Force in proceeding with such projects as X-15, the Dynasoar boost glide vehicles, the military satellite mentioned by General Schriever, the recoverable manned satellites, and the space probes about which you have been informed.

In the meantime, the means of propulsion to place man, the equipment to sustain him, and the tools to assist him in space flights, can be developed. The area of propulsion, specifically nuclear propulsion, is one in which I have immediate concern.

Accordingly, I shall confine my remarks to some of the views I hold on this particularly important aspect of any space program.

To reach, navigate, and explore space relatively near the earth, this is, out as far as Mars, I consider three basic propulsion systems must be provided:

First, a boost system to accelerate vehicles from the earth's surface to escape velocity;

Second, an auxiliary propulsion means for navigation, maneuver, et cetera; and

Third, a system for landing, presumably from orbit.

To put it in other terms we may need one propulsion system to start us on the space journey, another to insure we reach our destination, and a third to effect a landing at our destination.

These systems, I think, are separate and distinct technical developments, although it may turn out that a single system may be devised to perform all functions. Unless all are available, exploration of space may turn out to be extremely limited.

Payload has been one of the objectives of flight from the surface of the earth since aviation began. In cargo aircraft, bombers, and ICBM's, we strive to carry the heaviest possible payload.

So it will be again as we attempt to explore space. The sole disturbing feature of the Russian Sputnik II is that it weighs over 1,100 pounds, as compared with the 30 pounds for the largest United States satellite put up to date.

We will always want to place more mass in orbit or on the moon, or near planets, in the form of instruments, cameras, men, and so forth.

Beyond certain payload limits, it will cease to be practical or economical to use chemical boost propulsion and only nuclear propulsion can be considered for the more ambitious large payload missions.

It is interesting to note that with current reactor concepts, which will provide increased performance capability over chemical systems, only a very small faction of the available fission energy is converted to useful work. Because of inefficient use of available energy, the development potential for future nuclear systems is large.

You have probably heard during the course of your hearings comparative statements regarding chemical and nuclear propulsion in connection with rockets. The implication often made is that these systems are competitive.

I am convinced that they will not, in their developed form, be competitive at all, but, rather, complementary systems.

One or the other will be used, depending on the application or the job to be done.

The chemical rocket has not yet been developed to the limit of its performance, and its further development should be supported. The chemical rocket may become the workhorse for boost propulsion analogous to the piston engine in aircraft, and, accordingly, I foresee a continuing requirement for these chemical systems.

The nuclear rocket will be in a class by itself, for use when we wish to reach farther out and carry more payload than can be reasonably accomplished by chemical means.

I can remember well when I brought the first turbojet engine to this country from England, the jibes that were hurled by the piston engine proponents.

"Just a hot breeze in a windstorm," they said. Many of these same people, converted to the attributes of the turbojet and the jet

age, viewed with amusement the efforts of our chemical rocket pioneers until just a few years ago.

I do not wonder, then, that the present proponents of chemical rockets tend to underestimate the future of the nuclear rocket. This is a natural and often healthy aspect of our scientific evolution and progress.

Having devoted most of my career toward effecting progress in propulsion, I have lived through these cyclic advances and fully realize that I do not have to defend the new; new developments defend themselves in much the same way as new products that find their way to the market place in our industrial economy.

The important thing is to recognize the proper time to begin a new development, and once underway, to provide adequate and continuous support. It is not generally known, for instance, that the Air Force considered a nuclear rocket development program in 1946. In this instance, the timing was premature in view of the scarcity of fissionable material and the final application was not sufficiently clear to justify the funds required.

At a more appropriate time, in 1955, this program was reinitiated in the Air Force and, at the request of the Secretary of Defense, appropriate development effort undertaken by the Atomic Energy Commission.

The present program has the support of the Joint Congressional Committee on Atomic Energy and, of course, approval of the Congress.

The initiative and foresight of this decision in the pre-sputnik era was, in itself, imaginative and commendable. Although the resultant nuclear rocket propulsion program, Project Rover, has had a few ups and downs in finding support since that time, it is now, in my opinion, on a firm basis and adequately supported. If this support remains constant, I feel we can provide the nuclear propulsion devices necessary to support future space exploration.

I would now like to touch more specifically on the two programs under my direction in the Joint Office for Air Nuclear Propulsion of the Atomic Energy Commission and the United States Air Force which relate to space technology. The two programs I have reference to are:

1. The nuclear rocket propulsion program, Project Rover.
2. The systems for nuclear auxiliary power program, project SNAP.

You have been given an excellent treatise on the basic propulsion concepts that govern rocket propulsion, and why the nuclear rocket and ion rocket appear attractive by Dr. T. C. Merkle of the University of California Radiation Laboratory at Livermore.

I am sure there is little I could add to those technical details which are a matter of your record.

More recently, Dr. R. E. Schreiber of the Los Alamos Scientific Laboratory discussed certain details of the Rover program. Hence, as you know, the first reactor for the nuclear rocket propulsion program will be ground tested at the Atomic Energy Commission's Nevada test site late this year, and further testing of more advanced devices will follow periodically.

In these later test phases, the Air Force will provide Los Alamos specific support in the development of nonnuclear components under Los Alamos direction.

Under the centralized management of my office, it becomes possible to integrate the unique capabilities of each agency to the best advantage to get the job done expeditiously with the minimum dollar expenditure.

In this regard, the Atomic Energy Commission and the Department of Defense have been working in close harmony. We have kept the National Advisory Committee for Aeronautics abreast of our progress, and have received valuable consultant assistance from that organization.

The step-by-step program planned includes field testing at the Atomic Energy Commission's Nevada test site of devices developed at Los Alamos. Our test site, a 12.2 by 39.6 mile area adjacent to and immediately to the west of the bomb test area, is a spot where the release of radioactive particles can be made in comparative safety.

In addition, the Nevada test site was considered ideal because of the existing support facilities, personnel, and Government-owned wasteland that was available.

The isolation in the case of nuclear rocket testing is more for pro tection of the test personnel in case of accident, rather than concern for the surrounding communities, since contamination anticipated from rocket-engine testing is expected to be negligible.

I have previously referred to three basic propulsion systems, boost systems for earth escape and for landing at destination and a system for navigation and maneuver.

The foregoing remarks apply primarily to our current program to develop those nuclear boost systems that are required to obtain sufficient thrust to lift large payload rockets free of the earth's atmosphere and gravitational field.

Such nuclear systems would also have application in providing the deceleration necessary to effect landings on the moon and for takeoff on return flights—we could, possibly, utilize the atmosphere for partial deceleration on Mars and Venus.

The second system to which I referred, that to provide for navigation, maneuver, or other small perturbations to the basic flight path, might well be a small-thrust, high-specific-impulse, ion-propulsion device.

Let me give you a general idea of the ion-propulsion concept. Tiny, positive-charge ions can be accelerated and directed like the image-producing electrons in a television tube. A stream of these particles, accelerated by means of an appropriate electric field to speeds of many thousands of miles per hour, can produce thrust to the order of a few pounds. We say a few pounds here. We do not know how many pounds, but it depends on the size and complexity of the equipment.

For terra firma applications, this thrust would be ineffectual, but in space, where there is no air resistance and negligible gravity, a small acceleration over a long period of time is sufficient to propel rather heavy interplanetary vehicles through space at eventual speeds of many thousands of miles per hour.

Also, the application of such small thrust for short periods of time could provide necessary vernierlike corrections to the flight path of a space vehicle to correct for errors in navigation and the like.

While a certain amount of research has been completed on ion propulsion under the sponsorship of the Air Force Office of Scientific

Research, the National Advisory Committee for Aeronautics, industry, and other organizations, this propulsion mode is in its infancy as compared to the more powerful and shorter duration boost propulsion systems.

One fact is clear; this type of propulsion system, to be practical, will require large amounts of electric energy.

In my view, then, the success of ion propulsion, in part, lies in the development of reliable, long-lived, lightweight nuclear sources of electric power which are amenable to the space environment. As you know, this environment is demanding, indeed, in that there is negligible gravity and high vacuum.

A device designed to operate in this medium is subject to many, as yet unevaluated, effects such as cosmic ray and meteoric bombardment, which are certain to cause currently unforeseeable engineering difficulties.

An initial use of ion propulsion might be to send a small space probe to orbit Mars for reconnaissance purposes. The optimum manner in which to perform such a trip with an ion-propelled device is to start and finish from orbits about the two planets.

Accordingly, a large-boost rocket would be required to place the ion-propelled device in orbit, since it would not develop sufficient thrust to leave the earth unassisted.

By applying a small acceleration in the space regime of about one ten-thousandth that of gravity over a long period of time, it has been shown for example, that it is theoretically possible to place a 3,000-pound probe in the orbit of Mars in about 300 days. An acceleration of one-thousandth that of gravity would reduce this transit time to about 30 days.

I might add here that the figures I have given you, one ten-thousandth that of gravity and one one-thousandth that of gravity, are the extremes between which we feel it is feasible to build an ion device at this time. It is very dangerous, however, to predict weight until you have built prototype machinery which will give you an idea of what the weights will be. Before such an attempt is made,however, much development work must be done on the development of ion sources and nuclear-power sources.

Let me turn now to program SNAP, or the Systems for Nuclear Auxiliary Power program, which was initiated some 3 years ago, and has been increasingly active in this postsputnik era.

The development of lightweight, long-lived, nuclear-heat sources in the form of reactors and radioisotopes, and the efficient conversion of this heat to useful electric power is the aim of this Atomic Energy Commission program. These would find many uses for space application besides ion-propulsion devices.

As you know, the current small satellites require only a trickle of auxiliary electric power to operate their instrumentation. For example, Vanguard and Explorer need less than 1 watt to power their small transmitters. Sputnik I also is reported to be in the same category.

As our ambitions lead to more and more sophisticated uses for satellites employing television, recording devices, electromagnetic detection devices, more powerful multichannel telemetry, et cetera, electric-power requirements may easily go up to 10 kilowatts or beyond.

Powerwise, a 10-kilowatt electric-power output may be compared to a 12-horsepower outboard motor. Advanced vehicles requiring this magnitude of electric power represent considerable advances over the sputnik-type satellites, but are, certainly, in the foreseeable future.

In addition to a long and reliable life, an obvious requirement for satellite auxiliary powerplants is that they be lightweight since, for every pound of powerplant in orbit we must have—in present 2-stage chemical rocket systems—about 100 pounds of rocket takeoff weight. Future single-stage rocket systems employing nuclear power may reduce this ratio to about 10 for 1.

Fission energy released in nuclear reactors is well suited to the applications under consideration. Very compact reactors can be constructed and a wide range of output power is achievable.

Unlike chemical fuels, the energy content of fissioning U–235 is so large that the amount of nuclear fuel used over a long period represents an insignificant weight.

Again, the old comparison that 1 pound of U–235 is equivalent to about 2 million to 10 million pounds of chemical fuel serves as a useful comparative guide. On this basis, the 10-kilowatt electric unit would use only a very small amount of nuclear fuel in 1 year's operation.

Various methods can be employed to convert the reactor's heat output to useful electric energy. Thermionic emission, and thermoelectric devices, have the advantage of no moving parts, but are farther from practical utilization than conventional thermal-power cycles which use turbines and generators.

All have a common problem; that is, the employment of a high-temperature radiator to dissipate waste heat by radiation only to outer space. The ordinary means of cooling by the circulation of air is impossible, due to the high vacuum environment; therefore, the radiator must be operated at relatively high temperatures to dissipate heat efficiently by radiation to keep its weight down. The design of this radiator must be sufficiently sturdy to tolerate possible meteorite damage.

Many new methods are also of use in conjunction with another form of nuclear energy, radioisotopes. By 1975, it is estimated that the nuclear-power industry will have produced over 50,000 kilowatts decay energy in radioactive waste or radioisotopes. These radioisotopes can create heat when emitted alpha or beta particles are stopped and lose their energy in suitable materials.

It is also worthy of note that certain reactor-produced transplutonium elements, such as californium 254, decay by spontaneous fission and offer amounts of power up to 6,000 heat horsepower per pound.

Obviously, many factors must be balanced in using radioisotopes. The power requirements, sensitivity to radiation of the payload components, shelf life, and expected lifetime of the satellite or space vehicle must be weighed against the isotope's characteristic radiation, its half life, and the AEC's ability actually to produce it in quantity, according to schedule, and at a reasonable cost.

In obtainable form, the radioisotope cerium 144, for example, produces 4.5 horsepower per pound. With purification, this could be increased to almost 15 horsepower per pound—this is heat horsepower.

This isotope's power output decreases by a factor of one-half every 290 days, its half life. Thus, by including an excess amount of the

isotope initially, we could design a unit with a few years' life for a specified power level.

Other radioactive-waste isotopes, such as strontium 90, decay with longer half lives—28 years—but are somewhat lower in specific power.

As some of you may recall, gasoline was onetime a waste product of oil production. Cerium and strontium are both waste products in the production of nuclear power.

The price of isotopes produced by the Commission is determined by the cost of production. The cost per unit of radioactivity reduces greatly with increased production. Present demand, which is mostly civilian, is low, and prices are much higher than they would be if there were large-scale demands. Initially, the large demand will come from the military. However, we hope that many civilian uses will be developed from this program.

In contrast to nuclear-fission energy and radioisotope-decay energy, chemical fuels and the sun have both been considered as power sources for satellites, and the sun has been proposed to furnish power for satellites and space vehicles.

The attractiveness of the sun results from the fact that its radiation is a relatively constant reservoir of energy in free space, producing about 130 watts per square foot. Conversion of this energy to electricity can be accomplished directly with solar cells or by using a heat collector and employing a conventional heat cycle as with nuclear heat sources

A solar unit with a 10-kilowatt electric output using either photoelectric cells or a solar heat collector in conjunction with a thermal-power cycle, would need an area of about 2,000 square feet, and would weigh on the order of 8,000 pounds. Conventional heat cycles, using nuclear units, could accomplish this job with a 300-square-foot radiator.

Chemical auxiliary power units are relatively off-the-shelf items. Many military aircraft are equipped with small gasoline-fueled engines to provide several horsepower.

Assuming that we could use a gasoline-fueled unit, and neglecting the weight of the unit itself, a 10-kilowatt electric-power unit for an earth satellite operating only 30 days would require about 15 tons of fuel plus oxygen Obviously, if we expect to furnish modest power levels for reasonable lifetimes for very expensive satellites, we must use something else. Batteries are not much better, as they are a special form of chemical power and weigh even more.

The inadequacies of both solar and chemical sources of energy are apparent. The solar source has some advantages in the very small sizes, but is not competitive in the kilowatt range with the nuclear sources of energy, radioisotopes and fission reactors.

Actually, solar energy does not appear to be competitive above about 10 watts. The low weight per unit power of nuclear-energy sources makes up for the additional weight involved in nuclear shielding.

The foregoing briefly denotes why I believe that our space future will draw heavily on nuclear energy and the reasons we in the Office for Air Nuclear Propulsion are so intent on its development.

This completes my prepared statement.

I shall be very happy to assist in any way I can, and to answer questions

Mr. NATCHER (presiding). General Keirn, our chairman introduced a bill: H. R. 11881, which provides for research into problems of flight within and outside the earth's atmosphere and, generally, sets up and creates the NASA. This bill, as you know, General, incorporates the proposals made by President Eisenhower. Under this bill, we have a civilian-controlled space agency. Do you agree, General, that it should be a civilian-controlled group?

General KEIRN. Yes; it is my personal belief that it should be.

Mr. NATCHER. The bill provides, further, that there is to be a director. In your opinion, General, should the Director be a scientist, or should he be a successful businessman, well qualified as far as administrative ability is concerned, or what type of individual do you think he should be?

General KEIRN. It is very difficult for me to put a tag on an individual in terms of whether he is a businessman, scientist, or engineer. I think, actually, he has to have some of the qualifications of all three. Certainly, he has to be a man of some stature in the scientific community. He must be a man who understands scientific facts. He must be a man who can sift in his own mind some of the very complex problems that are essentially scientific in nature.

On the other hand, I think one must beware of a scientist who has devoted all his attention to a limited area. He may be an expert in this area, but he may not have the judgment required in other areas.

So for this reason, while I say this man should have a lot of characteristics and qualifications of a scientist, I think he should also be an engineer. I think he should be able to apply scientific knowledge in an engineering sense and be able to make decisions with regard to when a theoretical proposal is ready to move toward a hardware phase.

Then, of course, he has to be a good administrator because he cannot manage an agency of this size unless he knows how to administer, knows people, knows Government routine, and has a full understanding of these problems.

You have to find someone who has some of these qualifications in all three areas.

Mr. NATCHER. General, the bill further provides for a Space Board not to exceed 17 members, not more than 8 of the members are to be drawn from Government agencies and departments and at least 1 of the members of the Space Board is to be designated by the Department of Defense.

In your opinion, should all the military services be recognized on this Board and be represented, 1 from the Army, 1 from the Navy, and 1 from the Air Force? It says at least one member from the Department of Defense.

In your opinion, should there be more than one member?

General KEIRN. In my opinion the answer is "Yes." I could elaborate on that a little bit. I think I am aware of the desire on the part of the authors of the bill to provide for flexibility so that they would not be tied down and they would have to come back to Congress every time they wanted to change membership.

On the other hand, I think it is important that all of the areas of skill which fit into this space age have some kind of representation on this Board.

The Army, the Navy, and the Air Force are all interested and have major areas under their cognizance. I think they should have repre-

sentation. I would include, also, the Atomic Energy Commission.

Mr. NATCHER. I did not quite catch your last statement.

General KEIRN. I would include, also, the Atomic Energy Commission.

Mr. NATCHER. General, this bill, as you know, when enacted or some similar bill, will take the place of the NACA. This will be an operating agency, not an advisory agency.

Do you have any suggestions to make to the committee at this time concerning any provisions that should be in this bill or do you have any suggestions at all that would be of benefit to the committee from the standpoint of this particular type of legislation?

General KEIRN. I have studied the bill to some extent and discussed it with others. I have known the NACA for many, many years. I have worked very closely with them since 1938. The bill, as I read it, would create an organization which would function presumably in very much the same way as the NACA has functioned.

I think this has been very, very satisfactory. I think this has been one of the outstanding agencies as far as the scope of work and the ability to coordinate their efforts with other Government agencies.

I would not like to see this pattern disrupted. Now, aside from that, it is difficult for me from reading the bill, to know just how it would be implemented, to know whether this pattern would be followed or not.

I can only say in my opinion we should not try to disrupt the pattern of operation which I think has been very successful.

Mr. NATCHER. Mr. Feldman.

Mr. FELDMAN. General, you say the Agency has functioned very well, and we also hear that the military has functioned very well in this field. Then why is it that the Russians are ahead of us in this field?

General KEIRN. I suppose the proper answer is that we have not functioned well enough.

Mr. FELDMAN. Then do you not think we ought to get a new Agency that can function well enough and will get the cobwebs out of our system and do something?

We heard from General Gavin, we have heard from Admiral Rickover and from others, that this is a life and death struggle and yet at the same time we treat this thing as just another passing fancy. Do you not think we ought to do something about it?

General KEIRN. I certainly think we ought to do something about it. I am not sure that it is in this specific organization that we will find the answer or the reasons why we are behind the Soviets at the present time.

Mr. FELDMAN. Would you repeat that again?

General KEIRN. I feel personally that the answer as to why we are behind the Soviets is not wrapped up entirely in a question of organization. I think there are many facets.

Mr. FELDMAN. For example?

General KEIRN. Our whole national attitude I think is poor.

Mr. FELDMAN. Precisely. We are told that this is a great Agency; the NACA did a great job. We are told that the military has done a great job. You, in your statement, say that in 1946, such a program was suggested by the Air Force for the development of nuclear rocket propulsion.

General KEIRN. It was considered.

Mr. FELDMAN. It was not until 1955 that we got started. We know in between time it was discussed many times. We know it was vetoed by some of the people, by the former Secretary of Defense. That is an open secret.

Now, if we are going to get off the ground, do you not think that we ought to really clear the path completely and start in a new way to see that we are not hamstrung by past thinking?

General KEIRN. This is very difficult for me to answer, Mr. Feldman. I think we will lose time initially if we so disrupt our present organizational procedures and at least initially we would be a little slow in getting going.

Mr. FELDMAN. I am not toying with the idea or in any way attempting to interfere with present organization procedures except to this extent: I know that the military themselves recognize it because we know of the record that came down in connection with general duties and we know what you are doing, for example in this field.

But I do think that we have a clear line of demarcation in the record between some pretty dedicated people like General Gavin, as I mentioned before, and Admiral Rickover and Admiral Hayward.

On the other hand, they have the placid attitude on the part of others who say let us relegate this new Agency, just let us get started, let us extend the NACA a little more and in that way try to develop a program. That is not going to do it.

Do you not believe that we have to change our whole attitude?

General KEIRN. I am sure we have to change our attitude.

Mr. FELDMAN. And we have to go full speed ahead and not let anything stand in the way of this program because it is a very potent one. Do you recognize that?

General KEIRN. Yes, I do. I agree with your sentiments on that.

Mr. FELDMAN. Do you think that Dr. Dornberger was wrong yesterday when he testified to the fact that this is a life-and-death struggle?

General KEIRN. I did not hear his testimony.

Mr. FELDMAN. I can say that he did testify along those lines yesterday. In fact he used those words.

General KEIRN. I think it is most important to the future of our Nation to move expeditiously in the direction which this committee is deliberating on.

Mr. FELDMAN. Do you not think that the new Agency should be on the kind of level that is at least near the Cabinet level. Should not the new head of this Agency, for example, be a member of the Security Council?

General KEIRN. He is, I believe, appointed by the President.

Mr. FELDMAN. Yes; and confirmed by the Senate.

General KEIRN. Really I have not given it this much thought. I have no opinion whether he should be a member of the National Security Council or member of the Cabinet.

I can say it is my opinion he should be given a high post. He should be given a position of stature in our Government where he can say something.

Mr. FELDMAN. Is your program being supported completely, to the fullest extent that you think it is necessary?

General KEIRN. As a protagonist for nuclear propulsion, I can only tell you that I could use some more money.

Mr. FELDMAN. Are you satisfied that you have the people that can accomplish the job if you do have the money?

General KEIRN. I am satisfied that we have competent people doing the job.

Mr. FELDMAN. It has been said here that if we are to have a million-pound-thrust engine that it will have to be nuclear propelled. Would you agree with that conclusion?

General KEIRN. No; I think not. I think we can build a million-pound chemical engine. I did not mean to give the inference that you would have to use nuclear power to have a million-pound-thrust engine. I believe you can build a million-pound chemical engine. I believe, however, that a million-pound chemical engine would not get you as far into space as a million-pound-thrust nuclear engine.

Mr. FELDMAN. Why?

General KEIRN. Because of the specific impulse of the chemical system which is materially less than what we expect to get from the nuclear system.

Mr FELDMAN. Have you any connection with the military liaison between the Atomic Energy Commission and the Department of Defense?

General KEIRN. Yes, sir. I have never been a member of this military liaison committee but many of the relations between the Atomic Energy Commission and the Department of Defense are handled through the military liaison committee, so I am quite familiar with their method of operation.

Mr. FELDMAN. Is it a constant and continuous liaison?

General KEIRN. I would say "Yes" They have staff members that make it their business to follow certain lines of endeavor and keep in touch with them.

Mr. FELDMAN. Do you find their activities useful?

General KEIRN. Yes. I think that once an agreed upon relationship between the Commission and the Department of Defense has been established, and it is through the military liaison committee that such relationships are established, then there is the direct communication between the Department of Defense and Atomic Energy Commission

Mr. FELDMAN. Is there any delay caused by the establishment of that contact through the military liaison?

General KEIRN. There is the delay that is natural to discussions with a liaison group. I cannot say that there has been a kind of delay that has really affected the program.

Mr. FELDMAN. Would you say it has aided it?

General KEIRN. Yes.

Mr. FELDMAN. Under the new proposal the Board is advisory in nature and is required to meet no less than four times a year. The old NACA Board, which is the executive authority group on top which runs the present NACA, has been meeting, according to General Doolittle, Chairman of the Board, about 10 times a year.

The new Board, which would be the executive authority, would probably meet, say, 10 times a year also. Its function would be advisory and it is not created for the purpose of establishing liaison between NACA and any other agency, even though it is required to have at least one member of the military on the Board.

Do you feel that a liaison arrangement corresponding to one between the military and the AEC, of a general nature, should be established or set forth in some way in the new law for the purpose of insuring a continuous flow of information between the NACA and the Department?

General KEIRN. Let me say that in the past there have been established committees which have served this purpose between the NACA and the military departments and industry. I think these committees have served a very useful purpose and really have handled the kind of thing which you seem to have in mind. So I am not really of the firm opinion whether one should be so established by law or whether they can be set up as committees in a fashion similar to the ones we have had in the past.

Mr. FELDMAN. Dr. Dryden told us that the number of members on various committees is over 500.

General KEIRN. I believe it is very large, but they are not on one committee. They occupy key positions in Government, in industry, or with the NACA and they meet at frequent intervals to coordinate their activities in particular areas.

Mr. FELDMAN. For an agency engaged primarily in a research function, I can see where they might have a lot of committee members, but if you are going to get an agency that is going to try to accomplish something, build hardware, do things, when you have a number of committees in which the membership is over 500, are they not likely to "committee' things to death?

General KEIRN. I think these 500 are not on one committee, as you know.

Mr. FELDMAN. There are committees and subcommittees and so on, layers and layers and layers of committees.

General KEIRN. There are two kinds of committees. There are the committees who are appointed to review our programs at the governmental level, on an ad hoc basis. The committees I am referring to are committees of operating people who coordinate their respective activities to be sure that the efforts of the NACA, the efforts of industry, the efforts of the military services are all tied together.

This kind of committee is very useful. It is done in those cases where there is need for a coordination between the two independent agencies. General Schriever, I believe, has a committee on certain aspects of his program which ties in with his work. Committees of that nature are essential and are useful.

Mr. FELDMAN. Could you not cut out all these committees by simply having a liaison established by law?

General KEIRN. It is my opinion that you could not, because there are so many areas that require the individual competence of individual people on a particular committee. You cannot man a liaison committee with such people of sufficient stature. These people on the working committees I refer to are employed in laboratories, they are doing work, conducting their part of the work. Then they meet to see that they are coordinated with the work that other people are doing. I do not think you can get around that kind of committee.

Mr. FELDMAN. By establishment of the Atomic Energy Commission Act, that liaison is not only functioning on top but also in the manner you speak of, down to the very project itself.

General KEIRN. I believe we have committees outside of the liaison committee working.

Mr. FELDMAN. Precisely. Now I am exactly right where I started from. In other words, we began by having you tell us that the liaison committee, the military liaison committee between the AEC and the military is functioning very well. Then I am told that it is not really necessary. So I am in a kind of quandary at the moment. I guess it is because of the fact that maybe the NACA does not like to have anything new added into the law and for that reason many who have testified in connection with the law feel they should not have it in because the NACA does not want it in.

General KEIRN. This is not my reason in questioning it. I believe I have said I have not really resolved my thinking on this particular point. I do believe that the working committee arrangements as they have existed between NACA and the services have been useful. As to the purpose of a committee set up legally and by law, I think I have not analyzed the problem enough to really give you an answer.

The relationship of working between NACA and the services has been ideal.

Mr. FELDMAN. Do you feel that an extended or even a greatly extended NACA will accomplish the task of having us catch up with the Russians or, more than that, leapfrog them which is what General Gavin said we need to do?

General KEIRN. I believe we will do so provided there is a continuing effort on the part of Congress to see that we are provided with tools and funds that are necessary to do it.

Mr. FELDMAN. Do you not think it will be done by the men who head it and people who head it so that you can show Congress? Do you think, for example, if you had a corresponding situation like the one you ran into in 1946 where you had a program and then it was abandoned, that that would accomplish this purpose?

What I am trying to say is simply this: Instead of throwing the ball back to Congress and saying, "Give us money, press a button and make this thing work," it is going to take somebody on top who knows what he is doing and can do the job and who has the imagination and the guts, if you will, to push away all the obstacles that will confront him and get the thing done?

General KEIRN. I am surely in agreement with that, Mr. Feldman.

Mr. FELDMAN. So that it is not Congress that is going to be the one upon whose shoulders rests the accomplishment of this job, but it will be the person who is on top of this Agency; is that not so?

General KEIRN. Yes; you surely have to have the assistance of Congress when the budget comes up.

Mr. FELDMAN. And Congress can write the strongest bill in the world and if the person administering it does not do a good job, the purpose will not be accomplished.

General KEIRN. I agree with that 100 percent.

Mr. FELDMAN. So that what we need is the strongest kind of person to head this new Agency; is that not so?

General KEIRN. Yes; I think I can agree with that.

Mr. FELDMAN. He ought to be almost a superman.

General KEIRN. He will have to have unusual ability.

Mr. FELDMAN. More than unusual—great ability and respect; is that right?

General KEIRN. Yes.

Mr. FELDMAN. Do you feel that the nuclear-powered aircraft is competitive with or complementary to Project Rover? What priorities would you assign to each?

General KEIRN. First of all I consider them complementary. The manned airplane program, I believe, is the one you are referring to. I believe they are complementary. I believe they should have equal priority. I believe that Rover is fundamental to our long-range national well-being. I think the manned airplane program is a fundamental approach to a shorter range program and that is to retain deterrent power over Russia.

Mr. FELDMAN. The 1946 nuclear rocket propulsion system was in addition to the NEPA studies by Fairchild, or were these one and the same thing?

General KEIRN. I believe that NEPA probably looked at nuclear rockets. One of our first proposals, however, for nuclear rockets in 1946 came from the west coast. This was a specific application of nuclear power for rocket propulsion. This was the first presentation.

Mr. FELDMAN. Do you feel that thermionic and solar energy converters will eliminate such conventional power sources as steam and intercombustion engines.

General KEIRN. You say thermionic and I suppose you are also referring to the devices like thermocouples and the advances in that state of the art. It appears there have been some breakthroughs in that in the last year or two and it would appear that efficiencies now comparable to those you achieve from a terminal cycle may be possible.

Theoretically, they seem to be possible. We just do not know how to do it yet.

Mr. FELDMAN. You indicated that Sputnik 2 was over 1,100 pounds. What about the rumors that the sputnik actually weighed over 5,000 pounds?

I have heard that it weighed as much as 3,000 and I have heard 5,000 also. Do you have any information on that?

General KEIRN. I do not, Mr. Feldman. I think I have heard that rumor but I have no information on it to know whether there is any foundation for it.

Mr. FELDMAN. I have no further questions.

Mr. NATCHER. Mr. McDonough.

Mr. McDONOUGH. General Keirn, I think your statement is an excellent one. I think we can gain a great deal from your testimony. The 2 projects that you refer to, Dynasoar and Rover, in what position of implementation are these 2 projects? How close to possible implementation?

General KEIRN. I can speak for Rover. Rover is in the development state and we will have a nuclear reactor on test at the Nevada test site in the fall. Now, on the Dynasoar project, that is not a project for which I have responsibility and I cannot really tell you whether it is in hardware or merely in the study state. I do not know.

It has been studied quite extensively. I cannot tell you whether it has gotten into any kind of hardware stage or not. The X–15, of course, is a step in that direction.

Mr. McDONOUGH. In other words, Rover is a nuclear-powered vehicle?

General KEIRN. It is not a vehicle, just the machine for producing the thrust. So we might apply Rover to a device like Dynasoar. We have no plans to do that, but it could be so applied. Rover specifically is an effort to build a propulsion machine.

Mr. McDONOUGH. You may have answered this question about whether we should set up a commission form or an agency. Which of the two do you think will give us the quickest action and the greatest progress.

The Agency would have a board of 17 and a director and the Commission would have 5.

General KEIRN. I have read the bill. I have known the National Advisory Committee for Aeronautics for many, many years. I have worked very closely with them. I lean very much toward an organization which functions in a manner somewhat similar to the NACA. Whether or not there should be a 17-man committee or a commission, I have the feeling there should be a committee of rather wide competence.

I think in this respect I lean toward the board of 17.

Mr McDONOUGH. You are the liaison officer for the Air Force in the Atomic Energy Commission?

General KEIRN No, I have a specific position with the Atomic Energy Commission. I am Chief of the Aircraft Reactor Branch in the Reactor Development Division of the Atomic Energy Commission.

Mr. McDONOUGH. But your military assignment is with the Air Force

General KEIRN. My military assignment is as Deputy Chief of Staff for Development, Nuclear Systems, Headquarters of the Air Force

Mr. McDONOUGH. In your opinion, are we progressing as rapidly as we can both in the industrial potential and in the basic research that we are doing now, or should we need a stimulating program or crash program to move faster?

General KEIRN. I think we are making good progress in both research and in the actual development, particularly in the program with which I am associated. I cannot be truthful without saying that we can use some more funds.

Mr McDONOUGH. In the research field?

General KEIRN. It can be divided. We are pushing basic research about as hard as we have people of competence to do it. In the particular programs I am associated with there is a great deal of basic research that is setting out timetable so to speak; the development of high-temperature materials, this is one of our major problems. We have everyone on it we can find who is competent to do it. We are putting every effort on it and we are not hampered by lack of funds in this particular area.

Mr. McDONOUGH. We need to speed up our program on the development of energy propulsion elements, solid or liquid fuels. Are we moving as fast as we can in those directions?

General KEIRN. I have no responsibility in the chemical propulsion field. I cannot speak on that. I think General Schriever may have already spoken on that. From my discussions with General Schriever he is making good progress but he thinks perhaps he can make a little more.

Mr. McDONOUGH. Thank you very much.

Mr. NATCHER. General Keirn, on behalf of our chairman, Mr. McCormack, and other members of the committee, I want to thank you for the fine statement you have made this morning and for your appearance before our committee.

Thank you very much.

General KEIRN. Thank you, Mr. Natcher.

Mr. NATCHER. The committee will stand adjourned until Monday at 10 o'clock.

(Whereupon, at 12:40 p. m., the committee recessed to reconvene at 10 a. m., Monday, May 5, 1958.)

25973—58——74

ASTRONAUTICS AND SPACE EXPLORATION

MONDAY, MAY 5, 1958

House of Representatives,
Select Committee on Astronautics
and Space Exploration,
Washington, D. C.

The committee met at 10:10 a. m., pursuant to recess, in the caucus room, Old House Office Building, Hon. John W. McCormack (chairman) presiding.

Present: Representatives McCormack, Metcalf, Natcher, Sisk, Fulton, Keating, and Ford.

Present also: George J. Feldman, director and chief counsel.

The Chairman. The committee will be in order.

The first witness is Hon. Roy W. Johnson, Director of the Advanced Research Projects Agency of the Department of Defense.

We are very glad to have you with us, Mr. Director. I note you have a prepared statement. We will be very glad to hear from you.

STATEMENT OF ROY W. JOHNSON, DIRECTOR, ADVANCED RESEARCH PROJECTS AGENCY; ACCOMPANIED BY REAR ADM. JOHN E. CLARK, DEPUTY DIRECTOR, ADVANCED RESEARCH PROJECTS AGENCY, DEPARTMENT OF DEFENSE

Mr. Johnson. Thank you, Mr. Chairman.

Mr. Chairman and members of the committee; it is a pleasure for me to appear before your committee to discuss the Advanced Research Projects Agency activities and its organizational relationship with other agencies. I believe that ARPA's organizational relationship with other agencies is of the most interest to the committee so I will address my remarks primarily on that aspect.

Since ARPA was organized on February 7, 1958, we have spent considerable time working with other DOD staffs on our assigned projects. Our frame of reference has been the directive from the Secretary of Defense which gives to ARPA the responsibility for planning and directing advanced research projects involving space science and technology, ballistic missile defense, and other advanced research and development as assigned by the Secretary.

The projects which have been assigned mainly required coordination with the Director of Guided Missiles because existing vehicles, components, and facilities must be utilized. This method of operation is a precedent which will set the pattern for future ARPA projects.

In other words, it is not the intent to expand to a large organization that will require extensive laboratories and other facilities. Undoubtedly, however, there will be some modification of existing facility

complexes in order to keep from impairing effort which must be applied to weapons systems. I feel the important point is that existing organizations can be utilized. This approach not only saves valuable time but also costs much less money.

The Assistant Secretary of Defense for Research and Engineering is the staff adviser to the Secretary of Defense on all military research, development, and engineering matters. He will be informed on the activities which have been assigned to ARPA, and he will utilize the ARPA staff for technical and administrative reviews to the extent necessary to fulfill his requirements.

Another way of explaining our actions is that we have and will be assigned specific projects which we will manage and provide funds for implementation. This method of operation is the key to the important objective to be served by ARPA.

For instance, we will have the scientific capability to review, direct, and expedite research programs which in the past have been retarded because of the requirement that they be based on a military weapons system. The scientific capability referred to will be provided mostly by a contract with the Institute for Defense Analyses with a staff of about 25 scientists. However, many of the staff are also members of other committees, such as Dr. York's membership on Dr. Killian's committee. In this manner we will have access to the best scientific talent in the United States to assist in the acceleration of the national technological status.

In addition, such projects as the ICBM defense may become so large in the future that it would be advisable to consider a management-type contract in order to provide a means for tying together the many diverse developments required for the overall defensive system.

Our method of operation in the Department of Defense is to deal directly with the service agency that has the capability to accomplish our projects. This naturally bypasses many established channels but has the decided advantage of saving valuable time and money.

We realize that service agencies are already performing important missions. However, they are in the best position to state if our projects can be accomplished without disrupting other directed projects If our projects can be undertaken, then ARPA will write funding orders direct to the operating agency. We have already begun to function in this manner.

Some examples are the lunar probes, and the escape guidance experiment and associated ground equipment. The Army, Navy, and Air Force all will participate in these experiments.

Of course, in addition to the service participation, ARPA coordinates with other agencies outside the DOD such as the National Advisory Committee for Aeronautics, the National Academy of Science and the National Science Foundation.

The President has authorized ARPA to proceed with the projects I have just mentioned for a period of 1 year. In furtherance of his proposal for a National Aeronautic and Space Agency, he has directed that these projects be reviewed for responsibility. We have begun preliminary discussions with the NACA on this subject.

Last week the ARPA presented its fiscal year 1959 fund request to the Subcommittee on Department of Defense of the House Appropriations Committee. Of the $520 million requested, we have pro-

posed that $448 million will be utilized for military purposes associated with missile defense, military satellites, and space technology in the fields of propulsion, instrumentation, data handling and reentry phenomena. Seventy two million dollars was requested to continue the nonmilitary space projects of the type which have been authorized by the President. All of the funds requested represent our best judgment on what we can accomplish when all factors are considered, including the present status of technology.

On this planning basis, our overall objective is to expedite those projects which are of immediate national importance and interest, and at the same time to project ourselves into the future as far as possible on other type research.

Dr. York has discussed with the committee the general problem of dividing space research between the Department of Defense and the proposed NASA. I believe a civilian astronautics agency should be created with its own funds for use in pursuing its programs. However, military programs already demand the use of outer space for many uses for the protection of our country.

The legislation setting up a civilian group should not be so worded that it may be construed to mean that the military uses of space are to be limited by a civilian agency. This could be disastrous. It behooves the writers of this legislation to state positively this freedom clearly and without equivocation.

For example, if the DOD decides it to be militarily desirable to program for putting man into space, it should not have to justify this activity to this civilian agency.

We are at a point today where the world stood centuries ago when Columbus sailed westward, but we are much better prepared with the technical knowledge for exploration than was Columbus. The exploration of our atmosphere and the stellar system offers tremendous challenges and opportunities. If we plan now, we can approach the new era confidently and hopefully. To this end I believe that long-range planning should be undertaken immediately by a group composed of representatives of the NSF, NAS, NASA, ARPA, and others as deemed appropriate, under the guidance and overall direction of the President's Scientific Advisory Committee.

Regardless of who has the responsibility for these projects, considerable cooperation must exist in order to accomplish them. Insofar as possible, I believe that existing facilities and personnel must be utilized. Considerable scientific talent is available in the United States for the exploration of space and other advanced research. However, proper direction must be exercised to obtain the maximum benefit. ARPA is prepared to support fully any decision that is made in regard to a civilian controlled space agency.

I believe that substantial benefits will accrue from a well-planned and coordinated effort. This can and will be a fast-moving business, but the objective will be not only to advance our technological status but as an end product to maintain our national security.

I have with me Admiral Clark, Deputy Director, and we are both prepared to answer questions.

The CHAIRMAN. Do you have a statement, Admiral?

Admiral CLARK. No, sir.

The CHAIRMAN. I think it is very good to have you both here so that members can ask questions of either one of you, and you can

elaborate and make it sort of a panel. I like the results of that type of an atmosphere.

Mr. Johnson, you said, "I feel the important point is that existing organizations can be utilized."

That means, as you later indicate, that where there are conflicts or something might fall within what might be termed a gray area, somebody has to make decisions. Is that right?

Mr. JOHNSON. Yes, sir.

The CHAIRMAN. In your opinion, who would be the one to make that decision?

Mr. JOHNSON. I think, the way the legislation is contemplated now, it would have to be the President's Office.

The CHAIRMAN. Where in the bill would be the language to that effect?

Mr. JOHNSON. I infer, from the fact that the civilian Space Agency director will report to the President, or act in a reporting capacity to the President, this conflict will go to his office.

The CHAIRMAN. I will cover that a little later.

You have also stated, of course, as we know, on the civilian aspects ARPA was set up for a year——

Mr. JOHNSON. Yes, sir.

The CHAIRMAN (continuing). Which I think was a very wise thing to do. So somewhere in the Government we would have progress being made.

We all recognize and realize the importance of the military aspects. You do not have to argue that with members of this committee. The question is the kind of language that will accomplish the results desired both from a civilian angle and the military angle.

We all recognize, and you do not have to argue much, that much good has come to mankind on what might be called the civil side that has grown from military activity, not only now but for many years gone by. Yellow fever and many things can be cited where mankind has been benefited. So those things are understood, or should be understood, by legislators, and I know on this committee they are.

You say the President has directed these projects be reviewed for responsibility. Are you in a position now to give the committee more information as to how far the review has gone?

Mr. JOHNSON. Yes, sir, Mr. Chairman. I think I can give you this from memory. We have been in session for several weeks with Dr. Dryden's group.

The CHAIRMAN. With whom?

Mr. JOHNSON. Dr. Dryden of the NACA. At the moment I think we are in agreement concerning the lunar probes and the other satellites that were authorized by the President some 4 or 5 weeks ago. They would all be transferred after the calendar year, those not completed after the calendar year 1958, to NACA.

In addition, we are asking for approximately—is this classified, Admiral?

The CHAIRMAN. Do not give any classified information. If we want it we can get it in executive session.

Mr. JOHNSON. I can put it this way: We are asking for additional projects that will be shared by Dr. Dryden's group and ARPA. So that roughly $95 million——

The CHAIRMAN. $95 million?

Mr. JOHNSON. $95 million of ARPA's budget as now submitted to the Appropriations Committee, and if adopted by the Congress, would be transferred to NACA; $72 million of this would be purely scientific, and the other $23 million would be work shared that would be partly military and partly civilian.

The CHAIRMAN. For the record, will you explain what is meant in the appropriations by lunar projects?

Mr. JOHNSON. The lunar probes are orders on the Army for an attempt to launch satellites around the moon that would have equipment in them to take a very crude picture of the back side of the moon. We have placed a similar order on the Air Force to make a similar attempt using a different missile. We hope that both will be successful and will add to our knowledge of the atmosphere, or the air around the moon. We certainly will know more about the air around it and perhaps get a picture of the back side.

The CHAIRMAN. In your statement you also have broken down the $520 million you have requested, and you mention reentry phenomena. Can you give us any idea as to what the position of the Soviet is in connection with the reentry phenomena?

Mr. JOHNSON. It is a personal opinion, and I think there is some verification for it, that they have conducted experiments with reentry missiles. The hope was, I believe, when they put up sputnik with the dog in it they would return it safely. That is the supposition at least I have heard expressed by many people who have studied this matter.

We have money appropriated or will have money appropriated, we hope, to continue experiments in reentry phenomena in 1959, and I think we will accomplish this successfully. The problem is not as tough as people presumed it to be a year ago.

The CHAIRMAN. I can understand that.

Coming to the bill—I do not want to ask too many questions because I like to have the members of the committee participate as soon as possible—on page 2 of the bill, Mr. Johnson and Admiral, line 7, the previous lines create a civilian agency as provided in the bill, and then this says:

except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations.

Will you define what those words mean, to what extent that would give jurisdiction to the Defense Department to make final decision? Because under this language the Defense Department makes a finding of anything that is peculiar to or primarily associated with weapons systems or military operations; as I read the language, the new Space Agency would not have any voice.

Mr. JOHNSON. I believe that it might be construed that way; I think this language also could be subject to a different sort of interpretation. I think it might be interpreted that the military could not proceed on its own without participation of the civilian agency.

The CHAIRMAN. We all recognize, as I said, the importance of the military in the world of today and the foreseeable future. Under the language of the bill I can see where there would be a clash which all understanding minds should want to avert. We have to project our minds into the future and sort of see what might arise after we have completed the job on the legislative level and then it gets into the field of administration.

Of course, that can be met; I can see that. I just wanted to get your views, because it could be under this language where just men who are stubbornminded—you will find them everywhere, good men, but oftentimes men with hard views, stubborn views—who might say this gives the Defense Department complete authority as to procedure as to activities that may be peculiar to or primarily associated with weapons systems or military operations. They might say that covers everything. So it would be creating a civilian agency, but in name only.

Do you see the possibilities of that language there?

Mr. JOHNSON. I read the language just the other way. The way I read it would mean that things that are peculiar to or primarily associated with weapons systems of military operations shall be done in cooperation with, or on behalf of, the Department of Defense by the civilian agency.

The CHAIRMAN. Will you define, then—you cannot do it in every particular, but I think the record ought to show it—what is meant by that language?

Mr. JOHNSON. I have written some, what I think is, clarifying language to this point, which I would be glad to read.

The CHAIRMAN. We would be very glad to receive it.

Mr. JOHNSON. I could read this.

The CHAIRMAN. I think it would be well to read it into the record.

Mr. JOHNSON. This is the way I would like to recommend that the language read:

> The Congress further declares that such activities should be directed by a civilian agency exercising control over aeronautical and space research sponsored by the United States, except insofar as such activities may be—

then I struck out "peculiar to or primarily associated with weapons systems or military operations" and substituted "in support of or presumed to lead to the use of space for national defense, in which case the Agency"—and I struck out "may"—

> is authorized to act in cooperation with, or on behalf of, the Department of Defense is so requested by the Department of Defense.

The CHAIRMAN. Is that the viewpoint of the Department of Defense?

Mr. JOHNSON. No, sir; this is the viewpoint—well, it is the viewpoint of myself as Director of the Advanced Research Projects Agency. I have not discussed this within the Department of Defense outside of people associated with me in this Agency.

The CHAIRMAN. What would you mean by the word "presumed"? I understand what it ordinarily means, but it could be capable of different interpretations under different circumstances.

Mr. JOHNSON. I think it is advisable to have very broad language, and I have selected this word "presumed" because it is quite broad. I think there must be an interpretation here that would lead to exploration in military science without necessarily a specific military weapons system in mind. I believe it is very important for the Department of Defense to be permitted to explore military science ahead of actual need for that knowledge for weapons systems.

The CHAIRMAN. "In support of or presumed to lead to the use of space for national defense" is broader than the words "peculiar to or primarily associated with"—and I emphasize these words—

"weapons systems or military operations." It is broader than that. That is correct, is it not?

Mr. JOHNSON. Yes.

The CHAIRMAN. In other words, there may be other military activities besides military weapons and military operations alone.

Mr. JOHNSON. I feel very strongly that is true.

The CHAIRMAN. You think the greater scope would be more important in the light of the world today; is that correct?

Mr. JOHNSON. Yes, sir.

The CHAIRMAN. Would you put into the bill language that, in the event of disagreement, then the decision be made by the President? You intimated that would be done on the Presidential level through Dr. Killian and his committee.

Mr. JOHNSON. I feel this, sir: That, if this language which is recommended were substituted, there would be no cause for conflict. It seems to me the worst that could happen may be duplication of effort. But if it was clearly stated that the Defense Department could proceed in exploration of space, as it understands it, for national defense reasons, then I think the civilian agency would operate in parallel, and I believe in many cases they would share this activity voluntarily.

I think the problem here is created because it is not clear that the Department of Defense—this is my opinion—would be permitted to operate without the approval of the civilian agency. If that is made clear, that they do not need the approval of the civilian agency, then I think there is no reason for conflict.

The CHAIRMAN. Are there any other suggestions to any other parts of the bill, appearing as Director of ARPA?

Mr. JOHNSON. No, sir.

I am in agreement with the bill as it is now written, if this clarifying language is adopted.

The CHAIRMAN. You mean, agreement as far as the Defense Department is concerned, as far as your activity?

Mr. JOHNSON. Yes, sir.

The CHAIRMAN. On other aspects like the State Department, I do not suppose you would pass on them anyway.

Mr. JOHNSON. That is right.

The CHAIRMAN. I just add that for the record so your position will not be misunderstood to anybody reading the record.

Admiral CLARK. Could I amplify that?

The CHAIRMAN. Certainly. Join in any time you feel like it.

Admiral CLARK. I think we should point out here that one control on all of this would be the Appropriations Committee. If a proposed program is not funded, then obviously this program does not go on. The reason for this particular suggested change in wording is that the original wording implies the Department of Defense must have a blueprint of a weapons system before we could proceed with space work or space exploration, and this is entirely contrary to the very definition of research.

You cannot prepare a blueprint or even conceive a weapons system until you have done the exploratory research that will give you the necessary knowledge for this sort of thing.

Now, the human factors are aspects—for instance, the services, the Army, Navy, and Air Force, for years have had a very intensive program to determine the human factors, what happens to a man in

space, and we are interested not only in whether he can survive in space but whether he can perform in space. There is little sense in sending a man up simply as cargo. We want him to be able to perform some useful function.

When we find out these things—what happens to a man in space, what are the phenomena that he is subjected to, how can he behave under a weightless situation—then we can begin to put together a blueprint for a weapons system.

The CHAIRMAN. In other words, before you are able to determine your mission and role you have to know whether you are able to do it?

Admiral CLARK. Precisely; yes, sir.

It is even possible that there will not be weapons systems per se in space. We may have reconnaissance and this sort of thing. But we feel there will be weapons systems. There always have. All research and scientific knowledge that has come over history has found an application in national defense, and certainly in this day and age our scientific secrets have war capability.

The CHAIRMAN. This is a little bit afield from the bill itself. I read in a national magazine a few weeks ago of a possibility of the Soviets soon being able to launch a spy satellite able to track planes by radar and simultaneously to direct missiles for plane interception. Can you give me any information on that?

Mr. JOHNSON. We have a very complete, I believe, project being sponsored by ARPA that leads to a reconnaissance satellite that will do a great many things for us. We are some months away from completion of this project, but I believe we are as far along as anything we know now of the Russians in planning such a satellite.

The CHAIRMAN. I am glad to hear that.

Could you give me any information as to the progress—I realize the difficulty you may have with classified information—but if it is not classified—progress in the same field as might be made by the Soviets?

Mr. JOHNSON. No.

The CHAIRMAN. I know you gentlemen recognize at all times we have to be capable of retaliatory action. That is one thing we must never lose. I know you gentlemen realize that just as well as I do, if not better.

The only level on which we can deal, as I see it, is the law of self-preservation. I have felt that way for years. They may say they deal on the moral law and the law of idealism, but they cannot deny that the law of self-preservation applies to their people as to ours, as well as to any people in any other country.

As long as their intent is world domination, about the only level I can see—unless there is a change in their state of mind—operating with them is the level of the law of self-preservation.

If this becomes a reality, the article also says, the power of retaliation by our bombers would be severely reduced or lost in time. Is that so?

Mr. JOHNSON. I believe there is a very definite military value in having reconnaissance satellites in orbit, and I believe if Russia has one that is fully qualified to inspect us they will have an advantage. I mean, if they accomplish this ahead of us.

The CHAIRMAN. This word "except" in this language interests me very much. I was concerned about that word "except", because I did not want to be a party to creating a civilian agency and then saying

that it cannot exist. Yet I appreciate thoroughly the importance of the military.

Is it understood—I ask this for the record—that in case of disagreement as far as the Defense Department is concerned—and you are speaking for ARPA in particular, and if you can speak, either one or both of you, for the Defense Department, I wish you would state it for the record—is it understood that where there are honest differences then it is intended and understood they can go to the President or anyone designated by him to pass upon the question as to where jurisdiction should be?

Mr. JOHNSON. That is the understanding of the Department of Defense.

The CHAIRMAN. In other words, it is felt that putting in specific language is unnecessary because it is understood that it is there by implication anyway?

Mr. JOHNSON. That is right.

The CHAIRMAN. Mr. Metcalf, of Montana.

Mr. METCALF. Thank you, Mr. Chairman.

As I understand it, Mr. Johnson, you are suggesting that parallel organizations be set up, one a military organization and one a civilian organization?

Mr. JOHNSON. That is right, sir.

Mr. METCALF. And when you leave this language in your amendment—"Congress further declares that such activities should be directed by a civilian agency"—and such activities are development, testing, and operation for research purposes of aircraft, missiles, satellites, and other space vehicles, manned and unmanned, together with associated equipment and devices, you are only saying that such activities as relate to civilian use are included?

Mr. JOHNSON. Yes, sir.

Mr. METCALF. In your testimony you say:

> If the Department of Defense decides it to be militarily desirable to program for putting man into space, it should not have to justify this activity to this civilian agency.

Then there is no need to go to the President, is there, to determine whether or not the Department of Defense program should be programed ahead of the civilian agency program or to work out any conflict?

Mr. JOHNSON. Yes, sir.

At the moment, I think it is the interpretation within the Department of Defense and NACA that, if this bill is enacted, a man-in-space program would have to be a joint effort of the two; that it could not be done by the military alone.

Mr. METCALF. But it is your position that the language should be written so the military could do that?

Mr. JOHNSON. That is correct, sir.

Mr. METCALF. Then you do not agree with this first statement—

> declares that such activities should be directed by a civilian agency—

except as civilian activities only should be directed by a civilian agency?

Mr. JOHNSON. Correct.

Mr. METCALF. And military activities should be over here [indicating], directed by the military agency?

Mr. JOHNSON. Yes.

Mr METCALF. Does not that do what the chairman suggested; that you create a civilian agency in name only?

Mr. JOHNSON. Sir, I believe there is scientific exploration—let me put it this way: At the moment, I believe anything between here and the moon has military implications. Beyond the moon, at the moment—and I do not want to predict for too long—I think that is a civilian scientific sort of exploration. That line I draw arbitrarily, the moon, may change as time goes on, but I do think that the military would not be particularly interested in exploring Venus and Mars at this time. But I believe the scientific fraternity, adding to our knowledge of phenomena in space should be an objective of the country, financed by the country.

Mr METCALF. But, as I gather from your testimony, it is the concept that the civilian agency should be the secondary agency in case of any conflict between the two.

Mr. JOHNSON. No, sir. I believe that both agencies should be permitted to go independent roads, if they desire. I think they should be instructed to work together to prevent duplication. I think parallel lines of work are sometimes desirable and duplication, I think, could be prevented. I believe you will get cooperation if it is clear that each can go their own course.

Mr. METCALF But if the military agency decides that a program is militarily justifiable, it is your idea that the Department of Defense should be able to put it into operation without any justification to NASA?

Mr. JOHNSON. Yes, sir.

Mr. METCALF Does not that relegate the civilian agency to a secondary position?

Mr. JOHNSON In military affairs, it does; yes.

The CHAIRMAN Who is going to determine what is military?

Mr. JOHNSON. I think that is a very, very good question, and this is what bothers me, because I think that the Department of Defense, the military services, are in a better position to decide that, and I think that we, as a country, would prefer to have that kind of a decision made in the Department of Defense, rather than the scientific fraternity.

The CHAIRMAN. I will agree that most questions probably could be easily resolved. That is understood. But there are some that could not

I am wondering; this gives the Defense Department conclusive jurisdiction in the determination of what is military. That is correct, is it not?

Mr. JOHNSON. That is right, sir.

The CHAIRMAN. I can see where it could be very easily clarified, I think, by the addition of a few words where, in the case of a difference of opinion, the President or anyone designated by him should make the decision. Would you object to that?

Mr. JOHNSON. No, sir. I think there will be cases when the President's Office will have to do that.

The CHAIRMAN. In practical operation, I can see where anyone would say, probably in 95 cases out of a hundred, "Well, this is military, having in mind the world today." And I realize the difficulty of divorcing what is civilian from military, and I think any doubt should be resolved, as far as myself, on the side of safety.

If there is any doubt as to whether it is primarily military, and so forth, the doubt should be resolved, in the world of today, on the side of the military. Just expressing my own opinion. But I can also see where there might be some twilight questions, and I would think, from the overall concept of our Government, that it is civilian—and we know that without going into detail—that, from the military angle, some language to that effect, where the President or someone designated by him would make the decision, would strengthen the military.

Mr. JOHNSON. Do you wish me to comment on that?

The CHAIRMAN. Yes.

Mr. JOHNSON. I think you could do it that way, but, as this program accelerates, there will be daily decisions that must be made, almost hourly decisions. I have seen in the last 60 days, the tempo increasing. I think that, actually, the time will come, if we go this road, where you may have to have a vice president in charge of space to be so knowledgeable of what is military and what is not military that he can be sitting making daily decisions every hour on the hour. I cannot conceive of any other way to answer this sort of thing if there is going to be a constant difference of opinion. And I can see these differences of opinion increasing as we in the Department of Defense do more military-science exploration.

I think, if you tell the Department of Defense that in military science you are limited to other fields than this, we are making a mistake, because I believe Russia is not inhibited by demanding that there be a military weapons system conceivable and immediately ahead before they explore military sciences.

I think our country has to do more of this, too. It is there where we will come into conflict with the civilian agency, because they will say, "Well, this scientific effort has no military implication in it," and we will argue that it might. I think this could be a daily occurrence.

The CHAIRMAN. Is it not better to have some means of avoiding that, or at least having a decision made? Those questions are bound to arise.

Mr. JOHNSON. Well, sir, there are many fields of science that the Defense Department is now permitted to explore, and ARPA was set up to forward that kind of thinking in terms of complex work, such as defense against missiles. We have to begin now to study the phenomena that we have not studied in the past, on a more scientific basis. I think if we start now to exclude one field of science from the military, their operating freely in it, this would be a bad precedent.

The CHAIRMAN. I see you have in your proposed amendment the word "except," which sort of disturbs me. I create something and then I say "except," and that has a very deep significance to me.

Mr. JOHNSON. The word "except" is in the bill itself.

The CHAIRMAN. I know that. That concerns me in the bill.

Mr. Metcalf?

Mr. METCALF. Mr. Chairman, I am concerned, too, about the word "except," as written in the bill, and the ambiguity of the language. So, I am glad these witnesses brought it up. But, in taking the language of the suggested amendment along with the statement that has been presented here—if the Department of Defense decides it to be militarily desirable—it seems to me that puts the last word of authority in the Department of Defense. Is that what you intend to do?

Mr. JOHNSON. I think, as Admiral Clark has pointed out, this work will have to be approved every year by Congress in its appropriations. I do think that the President's Office would step in any time and arbitrarily make determinations contrary to the decision of the Department of Defense that an effort was military. I think we have the checks and balances in our present system that would make it impossible to go overboard as long as the space activities within the Department of Defense were centralized, as they are, in ARPA.

Mr. METCALF. But there would never need to be a resolution of the Congress between the civilian agency and the military agency, because, if the Department of Defense made a decision that a program was militarily desirable, it would have the last word in deciding whether to go forward with it, except, as you say, to justify it before the Appropriations Committee.

Mr. FORD. Would you yield?

Mr. METCALF. Surely. I yield to the gentleman.

Mr. FORD. It seems to me, when the budget is put together, as a practical matter, the Bureau of the Budget, in reviewing the funding requests by the civilian agency and the Department of Defense on behalf of ARPA, would make a decision as to the allocation of funds, and through the allocation of funds there would be a decision made as to whose responsibility it would be. Is that the way you think it would work, Mr. Johnson?

Mr. JOHNSON. That is correct, sir. I think you would have a wonderful control.

Mr. FORD. You see, before they can get the money, even request it of Congress, they have to justify their individual projects to the Bureau of the Budget, and, in that process of justification, a decision as to whether the program, A or B, would fall.

That is the initial decision, and then, of course, the Congress, in the approval of the respective budgets, would confirm or reject which agency would have the responsibility. Is that your interpretation of the way it would act, from a practical point of view?

Mr. JOHNSON. That is correct, sir.

Mr. FULTON. Will the gentleman yield on that point?

Mr. METCALF Yes; I will yield.

Mr. FULTON. What standards would the Bureau of the Budget use in making that decision? How would they formulate rules of general nature to come to such decisions?

Mr. METCALF. I agree that the Congress, through its appropriating function, would have a sort of a last word, but it has the last word no matter what kind of an agency we establish. If this committee would introduce, and the Congress would adopt, legislation that says that control of space shall be under the military, we would have the same appropriation control that we have under the suggestion you have made.

But it seems to me that the language in the bill—

Congress declares that such activities should be directed by a civilian agency—

is completely canceled out by the suggestion you have made and the testimony that you have presented. I am not in a position to say here whether or not it should be canceled out. I am just trying to get my thinking in line with yours. I cannot see how we are protecting anybody by this appropriating function that you suggest.

Mr. JOHNSON. I think the control of money is always the final control.

Mr. METCALF. That is granted, but that is here and inherent in our present system; no matter where we put the Space Agency, there will be this appropriating function and determination in the Bureau of the Budget.

Mr. JOHNSON. But, within specific approved programs, there is still the possibility of a great deal of leeway as to, for example, a man in space. The military have very definite ideas of the things they want a man to do in space. The civilian agency may have different ideas. To the degree that the military scientific explorations proceed as they wanted them to, to get the kind of data they wanted within that money, I think it is a very, very important decision to have remain with the Department of Defense.

Mr. METCALF. What would a civilian agency be doing now in space, except working on explorations on the other side of the moon?

Mr. JOHNSON. Sir, I feel that the civilian agency has a need for scientific exploration and the construction of vehicles that are necessary for that exploration. There is, I think, 20 years of exploration that will keep an agency very well occupied to get new data, new information which I do not think the military, at the moment, would be as interested in exploring.

Mr. METCALF. What would such a civilian agency be doing in the field of missiles?

Mr. JOHNSON. I cannot think what a civilian agency would want in the field of missiles.

Mr. METCALF. The bill says—

for the development, testing, and operation for research purposes of aircraft, missiles, satellites, and other space vehicles—

and it says—

such activities should be directed by a civilian agency.

Mr. JOHNSON. I presume the kind of missile a civilian agency would need would be a missile with a million, 2 million-, 3 million-, 5 million-pound thrust, an extraordinary thrust you would not need in an ICBM. To that degree, they would have an interest.

But missile technology is so wrapped up in the Department of Defense in dozens of projects of large magnitude, I do not think a civilian agency would want to start in and go on its own in a program of that kind. Certainly, they would rely on the military work to a great degree for cost reasons.

Mr. METCALF. Do you think that word "missiles" should be deleted for the purposes of clarity?

Mr. JOHNSON. No; I do not think that I would inhibit the civilian agency from proceeding, if they wanted to; the military may decide they were not interested in a 2 million-pound thrust, and they should not be precluded from developing one of their own if the military did not want to.

Mr. METCALF. Thank you.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. Mr. Johnson, as you probably know, a number of outstanding scientists in the country have appeared before our committee during the past 2 weeks. These gentlemen have made certain observations concerning this particular matter that our chairman has pointed out to you.

One of the scientists who appeared before our committee made a statement, Mr. Johnson, Prof. James A. Van Allen, the department of physics of the University of Iowa. He made two observations I would like to read to you and see whether or not you agree with them. The first one is this:

There will likely be many useful military applications of the results of space research. But, in my judgment, a much broader and more fruitful national program will result if the program objectives are not set by the demonstrated needs of military weapons systems and of other military applications.

Mr. Johnson, he made the further statement, and I will read it:

In the above it has been urged that the NASA be given dominant cognizance, among all Federal agencies, in the exploration and peaceful applications of outer space. The national security requires that the activities of NASA not adversely affect the development of specific weapons systems and the accomplishment of other short-term, specific military objectives. Decisions on the proper cognizance of areas in which a conflict of interest with the Department of Defense exists should be made, in general, in favor of the NASA—unless a clear and significant loss of military preparedness can be demonstrated to result thereby.

How do you feel about those two observations?

Mr. JOHNSON. I would disagree with Dr. Van Allen. I come back to the point I made earlier. I think it would be a tragic mistake to tell the Department of Defense that it could not explore a field of science unless there was a clear-cut military objective or a military weapons system in the planning. I believe that this would be a mistake.

Admiral Clark would like to comment.

Mr. NATCHER Go right ahead, Admiral

Admiral CLARK I would like to point out, first, that the bill does not restrict itself to astronautics, it also says aeronautics.

I question whether we would be farther ahead in aviation today if all of our aviation activities in this country had been under the direct control and management of a civilian agency. The things that have made our airlines great have been the work that has been done for military aircraft—large engines and this sort of thing.

Now, the NACA was during the same period making spectacular contributions, a wonderful organization, and one of the very reasons it was established. I think it could make the same contributions in astronautics and should.

Mr. NATCHER. Admiral, do you agree with the two observations I have just read that were made by Professor Van Allen, or do you disagree with the two statements?

Admiral CLARK. In the first statement, he said there would be——

Mr. NATCHER. Let me read it again right quickly. His first observation was:

There will likely be many useful military applications of the results of space research. But, in my judgment, a much broader and more fruitful national program will result if the program objectives are not set by the demonstrated needs of military weapons systems and of other military applications.

Admiral CLARK. I disagree with it, because the programs we have right now are not tied to a weapons system, pointed to a weapons system, they are pointed at the obvious things—reconnaissance. Reconnaissance is going to have a great interest to the civilian approach if we can predict weather and we learn a great deal about that part.

Now, the civilian scientific approach, it seems to me, would have a great interest in research which points to a better life to man on earth,

perhaps in the field of agriculture, medicine. Since we never know what scientific research is going to turn up, we might get clues as to the cause of cancer, this sort of thing.

Mr. NATCHER. Thank you, Mr. Chairman.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. I would like to ask Mr. Johnson with reference to the bill: As I understand, you are generally supporting this legislation we have before us, with possibly some changes as you suggest in this proposed amendment.

On page 3, section 4, where it is proposed to set up a board—I am referring now to line 20 on page 3—where no more than 8 members of the board are to be designated from appropriate departments and so forth, concluding with this language, "including at least 1 shall be from the Department of Defense."

Do you agree, in general, with the proposed setup for the membership on this Board, Mr. Johnson?

Mr. JOHNSON. I do not disagree. I think that it is possible under this language for the Department of Defense to be represented by more than one. As long as one representative is there, while I cannot speak for the entire Department, I think this is all right.

Mr. SISK. You think, then, that one member of the Department of Defense would be sufficient on this 17-man Board?

Mr. JOHNSON. Yes, sir.

Mr. SISK. We have had some testimony before us here—in fact, I think that almost without exception people from the military heretofore appearing before the committee have indicated they felt there should be at least 3 or 4 on this Board. Generally, I think the recommendations have been by several generals and admirals, both in the Army, Navy, and Air Force, that possibly there should be a representative from the Department of Defense who would be a civilian, and then possibly a representative from the three services.

You do not necessarily agree with that suggestion?

Mr. JOHNSON. I would not object if the language were changed to include representatives of the three military services as well as the Department of Defense. This would give continuity in the event of failure of the Department of Defense member to perform. I think that would be desirable.

Now, I am of this opinion: If the language is not changed, my recommendation is not followed, then I would certainly want stronger representation from the Department of Defense, because I think this becomes very critical then in the policy area.

Mr. SISK. In other words, that is what I am arriving at, Mr. Johnson.

As I understand you, this Board for control of space, this lunar space, must be under the control of the Department of Defense. If you can put in language here which will make the new Agency subservient to the Department of Defense, then you do not particularly care whether you have any representation on the Board or not. If you cannot get that kind of language in it, of course, you can see where you would want substantial representation. Is that not about right, Mr. Johnson?

Mr. JOHNSON. Not quite, sir. I would like to say it this way: That honestly I do not feel there is any need to say the civilian is subservient to the military or that the military is subservient, either

one to the other, if each are allowed to work out their own program and encourage to work together. I do not think the word "subservient" needs to become important here.

Actually, what I am concerned about is that a civilian agency will be set up that will be literally in control of all space, and this law, as it is worded, would mean all space one inch from the ground, not a hundred miles up.

The language here says that this Agency will control all space starting with this floor. And I think this is a very radical step to take, to put all space in civilian control.

Mr. SISK. For all practical purposes, we are a Nation believing in civilian control of all aspects of our Government. So that, in essence, even our military forces themselves are under civilian control and under a civilian Commander in Chief; is that not correct?

Mr. JOHNSON. Yes, sir.

When I said civilian control, I am sorry, I meant civilian agency control. I should have put in the word "agency" I think there is a distinction.

Mr. SISK. Actually, you made the statement a little while ago that you felt—if I understood your statement—that you felt there was substantial possibility for military exploration or military usage of the area I referred to as lunar, or that area of space out to the moon, and it would seem to me then that your discussion would more or less preclude any operational activities on the part of the new Space Agency in that particular area

I think that you possibly indicate that in basic research, yes; but in the practical application of an operational agency and operating vehicles, and so forth, in space, it must almost be under the domination of the Department of Defense, or at least subject to their veto.

Do I misstate that, Mr Johnson?

Mr. JOHNSON I would like to come back now again—as I interpret the language of this law, the law says that this civilian agency is going to be in control of all space, not just outer space, except for a military weapons system. I do not think that my suggested language would imply the military would be ruling the airlines or ruling civilian air transport. I think that there would be no more concept of that in outer space than there would be in space up 10 miles.

Mr. SISK You refer in your statement—and I believe possibly the gentleman from Montana referred to part of what I have in mind—on page 3, you mention that ARPA coordinates with other agencies outside the Department of Defense, such as the National Advisory Committee for Aeronautics, the National Academy of Sciences, and the National Science Foundation.

I have been concerned from the very beginning of these hearings with just where ARPA would fit into the situation in the future. That is, assume we set up a new space agency.

Let me ask you this: Just what do you propose a new NASA would do and the authority it would have above and beyond what ARPA, NACA, the National Academy of Sciences, and the National Science Foundation are doing and have authority to do today?

Mr. JOHNSON. I have asked myself that question.

Mr SISK It comes right down to this, Mr. Johnson, actually: Do you feel there is any need for this new Agency?

I mean that sincerely. I am not trying to get an argument with you. I appreciate your position.

I am just sincerely concerned, and I have sat here for the past 3 weeks and listened to the testimony on this and have really begun to seriously consider whether or not there is any particular niche for this new Agency unless we eliminate some of the present agencies, or just where it is going to fit in, just what authority it is going to have, just what capacity to operate that some of these other agencies do not already have, unless it becomes an overall guiding agency with authority to make decisions not only with reference to the Science Foundation and the Academy of Sciences but to ARPA and any other organization as well. I am becoming increasingly concerned about the usefulness of it at all.

Mr. JOHNSON. This bothers me, too, sir.

Mr. SISK. We approached this in the beginning, Mr. Johnson, with the idea there was some urgency about this. I realize the urgency, which I think was brought on because of a military situation. Would you agree with that?

Mr. JOHNSON. Correct, sir.

Mr. SISK. ARPA was set up primarily, then, as you visualize, to meet that military challenge; is that right?

Mr. JOHNSON. It was one of the reasons for establishing ARPA; correct.

Mr. SISK. Primarily it was an attempt to coordinate and to do the things that were necessary to meet the possible military challenge of a possible enemy country; is that correct?

Mr. JOHNSON. I think that is substantially correct, sir.

Mr. SISK. Let me ask you one further question here.

There has been quite a bit of testimony with reference to the need for an international understanding in space exploration due to the enormity of the task and the fact that it would be most desirable that space be kept peaceful and exploration of space be done in a peaceful manner and used for peaceful benefits.

What is your opinion, in general, on that? Do you think there are any possibilities of that? I mean, for all nations of the world.

Mr. JOHNSON. Sir, I think that, we should do it within the framework outside of the Communist bloc, paying the money, but perhaps sharing a knowledge with the other nations of the free world. We will do this anyway.

I think we might otherwise invite management problems that would injure or harm our progress. I believe we are better equipped to do it on our own.

I think the Russians will do it on their own. I think they clearly intend to. They recognize the opportunity here.

I think we must face up to this as a nation. I do not think we are going to run away from this problem by trying to push it off on the U. N. There is a little bit of fear psychology in this problem, I believe. The unknown now is bothering us, and I think there is a desire to say we can run away from this thing by wishing it to be civilian, to be peaceful, and to put it in the United Nations, and I do not think any one of those things is going to work.

We have to face up realistically to the new problem that is created for us on this world in our national security, and I do not think we can lose sight of that for one minute.

I do not want to make a speech, but I feel very strongly about this.

Scientists have said it is ridiculous to put a man in an instrument or satellite up there and drop a bomb, because the bomb will not drop. So we are supposed to believe this is ridiculous.

Actually, we do not know what the weapons of tomorrow are going to be. Work over the next 20 years might lead to a death ray, and if you had a death ray, that would be the weapon of tomorrow, and then obviously a man in a satellite up in the sky would be in a far better position to use judgment, to exercise control of that ray.

So what I am saying is: let's not look at the problem of tomorrow in terms of weapons of today and just automatically say that there will be no military uses of space way out, including the moon. If we think in terms of present weapons, that is probably right.

The bomb today is considered the ultimate weapon. I suspect 20 years from now the bomb will be passé as a weapon.

Mr. SISK. Getting back to the bill for just a moment again, Mr. Johnson, on page 2, on line 22, under subsection 6, we have these words in a statement of policy:

"Cooperation by the United States with other nations and groups of nations in work done pursuant to this act and in the peaceful application of the results thereof."

Of course, some think that is just high sounding language, but that is part of the declaration of policy.

As we discuss this further, I am becoming increasingly inclined to believe that on a close analysis of this bill, Mr. Johnson, you might find a number of things that you might not agree with in the legislation.

What do you think of that particular language?

Mr. JOHNSON. The International Geophysical Year was, I think, a wonderful thing. Even the Communist nations participated. I think that concept ought to be encouraged.

I think we are now in the framework where we can get scientists of different nations to do more work together. As it extends our knowledge of phenomena of space, I think it is a good thing.

But what I said earlier is that I do not think we can wish our problem off onto that body and say, "We have solved it, and we need not fear enemy attack from outer space because we have turned it over to peaceful scientists." I do not think that would follow, but I think it is a good thing.

Mr. SISK. I appreciate the discussion we have had this morning. I have been criticized by certain people with reference to a statement I made to the effect that, if all we were doing here was changing the name of some agency and winding up doing business as usual at the same old stand, all we were doing was spinning our wheels, and I am coming more and more to believe possibly I was right in that.

I realize the urgency, I think, of progress in this field, but I am wondering, after having heard your answers to some of the questions, if to some extent you might not be inclined to agree with my statement.

You do not have to answer that question. I do not want to put you on the spot.

Mr. METCALF. Will the gentleman yield?

Mr. SISK. Yes.

Mr. METCALF. In the same list of activities the gentleman from California was referring to is item No. 3:

that the activities should be conducted so as to contribute materially to the development and operation of vehicles capable of carrying instruments, equipment, and living organisms through space.

In your testimony you said if the Department of Defense decided it to be militarily desirable to program putting a man into space, it should not have to justify this to a civilian agency. As the bill is written, a civilian agency would be in control of putting a man into space. Is that not correct?

Mr. JOHNSON. This is a disputed area, and we have agreed to compromise, as you do in a dispute, and so we are saying now that we will share the responsibility between the two agencies.

Mr. METCALF. If the language you have submitted as an amendment were adopted, the Department of Defense would have the final decision?

Mr. JOHNSON. No, sir; no. The civilian agency—this clause I would not change, and I think the civilian agency ought to operate vehicles in space for exploration purposes that have no military implications. But if we put a man up there for military reasons, he may be in an environment, he may be asked to do things that you would not in a civilian agency ask a pilot of that satellite to do.

We ought to be free to create the kind of vehicles we need to protect us militarily, and they ought to be able to—it is just the same thing as a bomber and a passenger aircraft. Civilian agencies make passenger planes, the military makes bombers. There is no problem.

Remember now the language of this law also applies, I think to lower space as well as outer space, and presumably this Agency could operate vehicles in lower space as well.

Mr. METCALF. Suppose this language is left in the upper part of section 2 just as it is contained in the bill, and there is a conflict between the Director of NASA and the military as to who should direct a program for putting men into space, who would determine and decide that conflict?

Mr. JOHNSON. Well, sir the disagreement probably would be between my Agency and this new Agency. I would then go to the Secretary of Defense. If he agreed with my viewpoint, then presumably the Secretary of Defense and the Director of this new Agency would meet at Cabinet level, and attempt to settle the dispute between themselves. That failing, then I think they would go, obviously, to the President.

Mr. METCALF. And this is the only way in which a conflict could be resolved between ARPA and NASA?

Mr. JOHNSON. If the Secretary of Defense agreed with ARPA.

Mr. METCALF. Unless there is some additional language put in the bill?

Mr. JOHNSON. Correct, sir.

And I think the question there is, as time goes on, the day-to-day operating decisions that will be held up depending on clarification, which may become a great number, and this could be a very onerous task for the President of the United States to take on.

Mr. SISK. I have only one further question, Mr. Johnson, and that is this:

Do you believe that ARPA as it is presently constituted, with the power and with the authority it has, is capable of doing the job in

space, militarily speaking, to place us once more in a position of leadership in the world in the use of aeronautics and astronautics so far as its military application is concerned?

Mr. JOHNSON. Yes, sir; I do.

If the Congress approves the 1959 budget for the money we have requested, I am convinced that it is adequate to do this job and to do it at a reasonable cost.

Mr. SISK. Then do you not feel that the NACA, as presently organized, the National Science Foundation and the National Academy of Sciences are probably doing a capable job in the civilian research field in space today?

Mr. JOHNSON. Well, the research that has been done in 1958 has been very largely in the Vanguard program, which will cost in total maybe $110 million, and we have authorized using the Jupiter-C where there will be spent in 1958 perhaps another, I guess, $4 million. So we would be spending for civilian research in space $114 million. I think that is a pretty good number for the first year. This is calendar 1958.

Mr. SISK. So you feel with the present committees and organizations, both military and civilian, properly constituted, we are doing a job?

Mr. JOHNSON. I do, sir. Although I would like to say this:

That the budget I submitted is primarily a military budget. It does not include some civilian work that needs to be done. I do think that there is another program in scientific exploration that is not militarily valuable for the foreseeable years that should be done and ought to be included in money appropriated for the NACA——

Mr. SISK. That could be done——

Mr. JOHNSON. Or the Science Foundation or any other group.

Mr. SISK. That could be done simply by giving NACA additional contract authorization by the Congress and increasing their appropriation; right?

Mr. JOHNSON. Yes, sir.

Mr. SISK. Thank you. That is all.

The CHAIRMAN. What is that program?

Mr. JOHNSON. What program?

The CHAIRMAN. The one you just mentioned that you feel should be done that is not included in the present program.

Mr. JOHNSON. We included in our budget $72 million for additional—let's call it a satellite and a half a month through 1959. That would be scientific exploration.

There is a lot more we need to know about what is going on out there, and the best way to do it is with a satellite. That is a minimum program.

There is other work that needs to be done now in instrumentation and more telemetering equipment and that sort of thing, which needs to be added to the total effort.

We did not include that in our budget because we presumed that money will be appropriated to a civilian agency. Therefore, I do think that you must not take our budget and say that is good enough for the total space effort. More money is needed.

The CHAIRMAN. These questions lead up to what I interpret in the minds of some of the members—that under the bill there is not an overall control on policy over the whole space program, for example,

between ARPA and NASA, setting up priorities and making allowances, and so forth.

The questions asked by the members, as I interpret, are really connected with the fact that there is lacking an overall control so far as policy is concerned.

The President's reorganization plan for the Department of Defense, on which hearings are now being held by the Armed Services Committee, provides that the present Assistant Director of Research and Engineering shall become the Director of Research and Engineering who shall supervise (1) the Director of ARPA, and (2) the Director of Guided Missiles.

Mr. JOHNSON. Would you care for me to amplify my interpretation of that language?

The CHAIRMAN. Surely.

Mr. JOHNSON. The Secretary of Defense intends that the Director of ARPA and the Director of Guided Missiles shall continue to report directly to him as they have in the past. ARPA will have its budget as approved by Congress. It will be an operating agency, will have funds, and will let contracts.

The CHAIRMAN. Will he be under the new official provided for in the reorganization bill?

Mr. JOHNSON. Under the reorganization bill, it is my understanding it is not intended for the Director of Research and Engineering to have funds of his own.

The CHAIRMAN. To have what?

Mr. JOHNSON. Funds, money. But ARPA will have money.

The CHAIRMAN. How will that affect ARPA? Will that bring about any administrative effect in the work of ARPA?

Mr. JOHNSON. I will be glad to give you a copy of a letter we have in our records, signed by Dr. Foote, Mr. Holaday, and myself, where we have a working arrangement as to how we coordinate between each other, the directions we give where we need to in our field, and I think this is the way we will continue to work. All ARPA projects are looked at by the Assistant Secretary of Research and Development.

The CHAIRMAN. Will you put that in the record?

Mr. JOHNSON. We will be glad to.

(The information follows:)

OFFICE OF THE SECRETARY OF DEFENSE,
Washington, D. C., April 7, 1958.

MEMORANDUM FOR THE SECRETARIES OF THE MILITARY DEPARTMENTS; THE CHAIRMAN, JOINT CHIEFS OF STAFF; THE ASSISTANT SECRETARIES OF DEFENSE; THE GENERAL COUNSEL; THE ASSISTANTS TO THE SECRETARY OF DEFENSE

The attached memorandum and chart delineate the relationships between the Assistant Secretary of Defense (Research and Engineering), the Director of Guided Missiles and the Director of the Advanced Research Projects Agency, pending Department of Defense reorganization along the lines recently proposed by the President

The Secretary of Defense has approved the dissemination of this memorandum and chart for the information and guidance of all concerned.

PAUL D. FOOTE,
Assistant Secretary of Defense (Research and Engineering)

WILLIAM M. HOLADAY,
Director of Guided Missiles.

ROY W. JOHNSON,
Director, Advanced Research Projects Agency.

OFFICE OF THE SECRETARY OF DEFENSE,
Washington, D. C., April 7, 1958.

To: The Secretary of Defense.
From:
The Assistant Secretary of Defense (Research and Engineering).
The Director of Guided Missiles.
The Director, Advanced Research Projects Agency.

PROBLEM

To delineate the relationships between the Assistant Secretary of Defense (Research and Engineering), the Director of Guided Missiles and the Director, Advanced Research Projects Agency.

DISCUSSION

The ASD (R and E) is the staff adviser to the Secretary of Defense on all military research, development and engineering matters. He is responsible for recommending to the Secretary of Defense basic policies governing military research, development, and engineering efforts by DOD activities and for recommending an integrated DOD research and development program to meet military requirements which will assure that there are no gaps and will eliminate undesirable duplication. In order to carry out effectively these responsibilities, he must be informed on all military research, development, and engineering efforts within the DOD, including those research and development projects assigned to the Director of Guided Missiles and the Director of ARPA.

In carrying out his responsibility to advise the Secretary on all research and engineering proposals within the DOD, the ASD (R and E) must determine that the proposals are technically sound, administratively feasible and in consonance with the overall policies and program objectives of the DOD. He provides through his own staff for the technical reviews and program analyses of all military department research and development projects except those assigned to the Director of Guided Missiles in which case he utilizes the staff reviews and analyses made by the Director, supplementing or complementing these to the extent necessary to insure that all aspects of these programs are covered. So far as ARPA projects are concerned, the responsibility of the ASD (R and E) is the same as for the military department research and development programs, but as in the case of the Director of Guided Missiles, the ASD (R and E) utilizes the ARPA staff technical and administrative reviews to the extent that these satisfy his requirements.

The Director of Guided Missiles is a staff assistant to the Secretary of Defense with certain delegated line authority for the direction of all activities in the DOD relating to the research, development, engineering, procurement and production of guided missiles. The staff functions that he performs with respect to the research, development and engineering efforts of the DOD for guided missiles projects are similar to those performed by the ASD (R and E) for all other military research, development and engineering projects. The difference is more a matter of emphasis and scope than anything else. He is an expediter who is responsible for one principal segment of the total research, development and engineering effort plus the procurement and production aspects after development is completed. The Director of Guided Missiles looks to the ASD (R and E) for advice and assistance in broad research and development fields (such as basic research, electronics, fuels, materials, nuclear applications and piloted aircraft) which are not exclusively involved in guided missile projects, but may have an effect on those projects He performs the technical reviews and program analyses for all guided missile projects and keeps the ASD (R and E) and the Director of ARPA informed on status of an important achievements and requirements in the research and development aspects of guided missiles.

The Director of ARPA is primarily a line official with responsibility for planning and directing advanced research projects involving space science and technology, ballistic missile defense, and other advanced research and development, as assigned, by the Secretary of Defense. In this role, he deals only in the research and development aspects of projects assigned to him. Ordinarily, these projects will be of a nature which would be outside the assigned missions of the 3 military departments or would be of interest to or involve 2 or more military departments and it would be in the best interest of the department to have an agency not a part of one or more of the military departments to pursue the research and development effort. When a project assigned to ARPA has passed beyond the research

and development stage, it will be assigned to one or more of the military departments or other appropriate agency for engineering, production, and utilization. In addition to the line responsibility, the Director of ARPA serves in a staff advisory capacity to the Secretary of Defense for certain matters such as recommending proposals for advanced research which may be conducted by his agency, or under his supervision by the military departments, and performing technical reviews and program analyses for research and development projects assigned exclusively to ARPA. The Director of ARPA is also responsible for keeping the ASD (R and E) and the Director of Guided Missiles informed on the status of and important accomplishments and requirements in his assigned projects which may have an effect on their assigned projects or responsibilities. He also looks to the ASD (R and E) and the Director of Guided Missiles to keep him informed of the accomplishments in their respective assigned projects which might have an effect on his assigned projects.

The relationship between all three individuals is one of close interdependence from the standpoint of keeping each other informed as to the breakthroughs, advances and requirements in their respective fields. The Director of Guided Missiles and the Director of ARPA probably have a closer and considerably different relationship than either has with the ASD (R and E), because many of the vehicles and components, developed for military weapons systems under the direction of the Director of Guided Missiles may be utilized by the Director of ARPA in research, experimentation and testing of certain vehicles or components required for the exploration of outer space as well as for anti-missile-missiles development. Similarly, it is expected that new scientific knowledge, advances and improvements discovered in the research and experimentation projects conducted by the Director of ARPA may be utilized to effect improvements in the research, design, and development of guided missiles carried out under the direction of the Director of Guided Missiles. On the other hand, both of them are dependent upon and utilize advances and breakthroughs in the broad fields of research and development specifically assigned to the ASD (R and E) and vice versa.

As long as the total effort in weapons research and development is adequate to meet the weapons requirements of the military services and the quasi-military requirements for outer-space exploration, there will be no problem. If the effort is not adequate, then priorities will have to be established by the Secretary of Defense. The attached chart depicts graphically the working relationships between the ASD (R and E), the Director of Guided Missiles and the Director of ARPA as outlined herein.

IMPLEMENTATION

If you concur, a joint memorandum presenting the above statement of relationships together with the attached chart will be published for the information and guidance of all concerned.

RECOMMENDATIONS

That you approve and authorize the publication of the proposed joint memorandum and chart.

The CHAIRMAN. In other words, the authority of ARPA to make contracts now would not pass to the new Director of Research and Engineering?

Mr. JOHNSON. It would not.

The CHAIRMAN. Mr. Fulton.

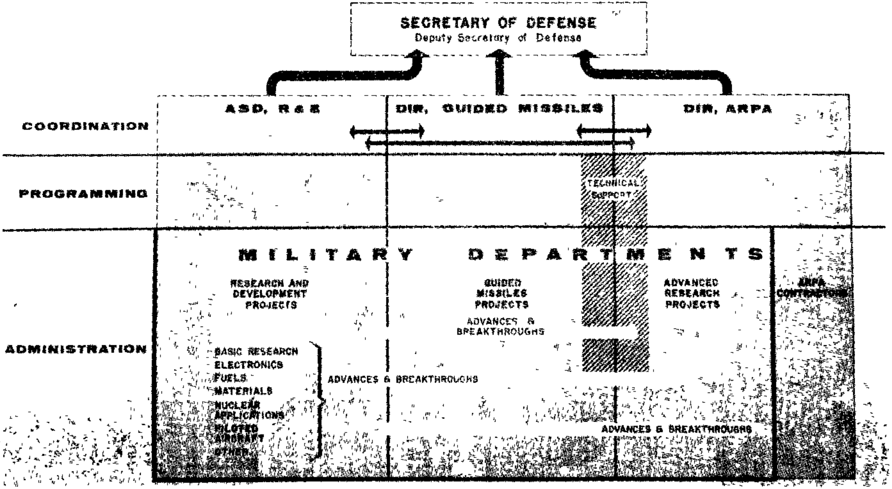
Mr. FULTON. I am glad to have you here.

In order to clear up a previous point that has been discussed, there was a question of the Bureau of the Budget deciding which would be military and which would be civilian space programs.

My question has been previously: What standards would the Bureau of the Budget use in coming to such a decision?

Referring to the discussion here between Mr. Metcalf and Mr. Ford, in which it was commented that possibly the money power of the Budget would really be deciding the function between the civilian and military, actually the inference to my question is that I thoroughly disagree with that, that I do not believe that is the place for that decision to be made between civil or military space programs.

DEPARTMENT OF DEFENSE
RELATIONSHIPS AMONG R&D ACTIVITIES



Mr. JOHNSON. This is the way it works. It is my understanding, however, that after moneys have been finally approved there is some freedom within programs using those moneys.

Mr. FULTON. You see, not that this is the way it works, but how should this committee plan that the best decision should be made in the future?

Mr. JOHNSON. I think that we have here a case where, if the Department of Defense is in disagreement with the Bureau of the Budget, then, too, we would have to go to the President for the final adjudication before the appropriation is submitted to the Congress. This does work now.

I think this new system, or this system we are talking about as it affects space would be functioning in that kind of an environment.

Mr. FULTON. Why not have an overall Space Agency which carries out the national space policy as outlined by Congress and legislated by the Congress? This Agency would have a seven-member commission form of government and would have on it military as well as civilian representatives. It might have under it the existing NACA structure as well as another structure that may be called NASA, the Astronautics, and it might have as a member of the Commission, for example, the Director of ARPA, or Dr. York, the scientist.

Mr. JOHNSON. I certainly think this is one way to do it. The problem, as I see it, is simply this: If many years ago the Atomic Energy Commission had been set up on the basis of atoms for peace, and it had been atoms for peace oriented, I do not believe the Congress over the years would have—and this is purely a personal opinion—appropriated the money needed to carry it where it has gone. I do not believe that the military aspects of atomic energy would have been prosecuted with the same force. This is a personal opinion.

The problem, in my mind, when you create this kind of an agency, if it is oriented to be atoms for peace, space for peace, then as a citizen I will be greatly concerned about the end result and the national security.

Mr. FULTON. The alternative, as you suggest, is based on space for war.

The CHAIRMAN. May I interrupt?

Mr. FULTON. Yes.

The CHAIRMAN. I am Acting Speaker today, so I have to leave. I have other jobs and other duties. And two of the members have to be on the floor.

After Mr. Fulton finishes, could you come back at 2:30?

Mr. JOHNSON. Yes, sir.

Mr. FULTON. The alternative that you leave open then, is, if you emphasize the fact that atoms might not have produced such a good result if it had not been first military and then expanded, when you apply that reasoning to the future space program it comes up against the alternative of having space used for military purposes, which in the end means war.

Now, I am always intrigued by every person who comes up before congressional committees from the executive departments and agencies because they are always willing to save the country, but preferably through their own departments.

Mr. JOHNSON. Yes.

Mr. FULTON. They think that is the best way to save it. So I compliment you on running true to form, and it is rather a good view on what you think your Department has done.

The problem then comes up: Shall we have two space policy-setting bodies, one for security or war purposes, the other for peace and exploration purposes, and then have the Office of the President act as the arbiter from day to day, week to week, and month to month as the various projects come up?

To me, that is putting too big a burden on the President and is an impossible method of avoiding the decision, the belief that Congress should set up an overall Space Agency under a policy guidance by the President, with the administration of the Agency in its seven-member Commission, on which both military and civilians sit, having unison—it may be Astronautics or ARPA or the various Army Ordnance components—but that Congress itself should set the standards of what is military and what is civilian as to the program in space, leaving the Agency to work out a method of operation.

Do you agree with that?

Mr. JOHNSON. I do not think I could give an offhand opinion on that.

Mr. FULTON. Would you submit it in the record?

Mr. JOHNSON. I will do so; yes, sir.

Mr. FULTON. In the bill itself there are provisions that give a period of time within which a particular agency can, by its own consent, transfer facilities and personnel to the new NASA Space Agency, but there is no particular way that the National Space Agency can get those facilities and personnel by order of the President if the Agency just sits down.

Do you think it should be set up so the President is specifically given the power and authorization to direct ARPA or the Department of Defense to turn over to the National Space Agency programs, facilities, personnel, and equipment?

Mr. JOHNSON. I again would not like to answer that off the cuff. I would like to be permitted to have some time.

(Mr. Johnson later submitted the following letter:)

GENERAL COUNSEL OF THE DEPARTMENT OF DEFENSE,
Washington, D. C., May 12, 1958.

HON. LYNDON B. JOHNSON,
Chairman, Senate Select Committee on Space and Astronautics,
Washington, D. C.

DEAR SENATOR JOHNSON: Mr. Roy Johnson, Director of ARPA, and I left an executive session of the House Select Committee on Space and Astronautics at 4 o'clock this afternoon, at which time he had an engagement to fly to Massachusetts with a group of other persons on a mission connected with ARPA activities. He asked me at that time to write this letter to you on his behalf, in order to fulfill his undertaking to let you know if language was developed which was satisfactory to him to alter the provisions of S. 3609 (and the corresponding House bill), in order to meet the concerns which he had with the original language of those bills.

As a result of consideration of the matter today before the appearance of Mr. Roy Johnson before the House Select Committee, Mr. Johnson was able to report substantial agreement within the executive department upon the following two changes in S. 3609:

First. Strike out on lines 9 and 10 the following:

", * * * in which case the Agency may act in cooperation with, or on behalf of, the Department of Defense."

Substitute for the language thus stricken out the following:

"in the case of which activities the Department of Defense shall be responsible."

The whole sentence beginning on line 4, as a result of the above change, will read as follows:

> "The Congress further declares that such activities should be directed by a civilian agency exercising control over aeronautical and space research sponsored by the United States, except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations, in the case of which activities the Department of Defense shall be responsible."

Second, on page 3, line 20, substitute the single word "nine" at the beginning of the sentence for the four words "no more than eight"; and also on line 23 substitute the word "three" for the word "one".

The provision thus amended, appearing on lines 20 to 23 inclusive of page 3 will, therefore, read as follows:

> "(1) Nine of the members of the Board shall be designated from appropriate departments or agencies of the Government of the United States, including at least three who shall be from the Department of Defense."

Mr. Johnson testified that with these changes he believed that his expressions of possible concern had been met and that the bill as thus changed was in his judgment entirely satisfactory.

Very sincerely,

ROBERT DECHERT.

Mr. FULTON. You can include your views in the record.

On the $72 million you recommend for civilian space projects during the coming fiscal year, do you not think that a recommendation of 86 percent for military and quasimilitary as against 14 percent for civilian program projects in space is rather a lopsided recommendation?

Mr. JOHNSON. Mr. Congressmen, I would like to clarify this budget. ARPA is asking for $520 million. The missile defense against the ICBM is $157 million of that. The military reconnaissance satellite is another very, very large number. If we take the balance, the percentage would be two-thirds and one-third.

What I am trying to say here is that I think a better number is one-third civilian and two-thirds military of what is left.

Mr. FULTON. Thank you.

Could I refer you to page 4, and then I am through?

Mr. FORD. Will the gentleman yield?

Mr. FULTON. Yes.

Mr. FORD. Should it not be said, if I understood your previous testimony, Mr. Johnson, in addition to the $520 million, of which you say two-thirds is for military and one-third for civilian, there is an additional sum in fiscal 1959 that would be requested, or should be requested, for the space agency on the civilian side?

Mr. JOHNSON. I would like to be allowed to answer that in this way: Congressman Fulton, with regard to the statement you made that I am running true to form in defending this agency. I have been working very closely with NACA on the assumption they will be created, this Space Agency. I have actively helped them prepare their budget. I know what the budget is that they are submitting to the Bureau of the Budget.

Mr. FULTON. What is the amount of the NACA budget that should be used for civilian space program in 1959 fiscal year?

Mr. JOHNSON. I am recommending a total of $95 million to be transferred from the ARPA budget to this new Agency. They in turn are requesting an additional amount, which I do not think they will want me to discuss here this morning. However, it is going in a

joint letter to the President that is being signed by the Secretary of Defense and by Jimmy Doolittle.

Mr. FULTON. With the chairman's permission, may we have that letter put in the record when issued? That will clear up the point.

Mr. METCALF (presiding). There is no security in the letter?

Mr. JOHNSON. We can give you a version of it that is security free. This letter is in the course of preparation now.

Mr. FULTON. Would you submit it for the record, with the chairman's permission?

Mr. JOHNSON. Yes.

Mr. METCALF. Without objection, it will be put in the record.

(The letter follows:)

ADVANCED RESEARCH PROJECTS AGENCY,
Washington, D. C., May 28, 1958.

Mr. HARNEY BOGAN, Jr.,
Assistant Counsel, House Select Committee on Astronautics and Space Exploration, New House Office Building.

DEAR MR BOGAN: The joint letter to the President from the Department of Defense and the NACA, referred to on page 2422 of the transcript, has not been issued as of this date

Sincerely yours,

L. P. GISE,
Director, Program Control and Administration.

Mr. FULTON. On page 4, at the end of the first paragraph, I am going to refer you to the limitation on the future as to space program projects. You say:

On this planning basis, our overall objective is to expedite those projects which are of immediate national importance and interest, and at the same time to project ourselves into the future as far as possible on other type research.

"As far as possible" has inherent in it a limit. The limit could be, first, time, money, ideas, facilities, personnel, or projects. What are the limits that you are referring to there? Are you limited by money? Are you limited by ideas and brains? Are you limited by the type of practical projects you want to get into?

You say "as far as possible." What is your "possible"?

Mr. JOHNSON. At the moment we are entirely limited by our ability to see ahead

Mr. FULTON. Do you not have a lot more projects you would like to be doing than you have the money for?

Mr. JOHNSON. Oh, that is always true; yes.

Mr. FULTON. Do you not have a lot more practical space projects that are really advantageous and could be followed up but we just have not gotten the country aroused to help you on?

Mr. JOHNSON. Oh, yes, sir.

For example, the 100 million-pound-thrust engine——

Mr. FULTON. You mean, 1 million-pound.

Mr. JOHNSON. Yes; excuse me

As a matter of fact, we are even taking a look at 5 million pounds. Yes; a crash program on that would enable us to spend 10 times the money we are planning to spend.

Mr. FULTON. Yes.

But when you refer to a possible death ray resulting in the future in outer space, you do not have in mind any practical program at this time to develop a death ray, do you?

Mr. JOHNSON. No.

Mr. FULTON. And there is no inference you are working on a death ray; is there?

Mr. JOHNSON. There is not. That was a hypothetical possibility I raised.

Mr. FULTON. You are not working on an antimatter program; are you?

Mr. JOHNSON. No; we are not.

Mr. FULTON. Thank you. That is all.

Mr. METCALF. Thank you. As I understand it, the other gentlemen need to go to the floor.

So the committee will be in recess now until 2:30, at which time the interrogation will proceed with the gentleman from New York.

(Whereupon, at 11:50 a. m., the select committee recessed, to reconvene at 2:30 p. m. of the same day.)

AFTERNOON SESSION

The CHAIRMAN. The committee will be in order.

Mr. Keating.

Mr. KEATING. Thank you.

Mr. Johnson, at the morning session, you discussed and put your finger on what is certainly one of the most troublesome aspects of this legislation to all of the members of this committee. And you suggested this proposed language to be substituted on page 2.

Now, taking the language which you have suggested, it would provide for the creation of this civilian agency which would have control over all aeronautical and space research, except those activities in support of or presumed to lead to the use of space for national defense in which case they would only be authorized to act if so requested by the Department of Defense. That would mean that if they were not requested by the Department of Defense they would have nothing to do with those matters.

That is your understanding; is it?

STATEMENT OF ROY W. JOHNSON, DIRECTOR, ADVANCED RESEARCH PROJECTS AGENCY, ACCOMPANIED BY REAR ADM. JOHN E. CLARK, DEPUTY DIRECTOR, ADVANCED RESEARCH PROJECTS AGENCY, DEPARTMENT OF DEFENSE—Resumed

Mr. JOHNSON. Correct.

Mr. KEATING. Now, let us assume that the Department of Defense did not request them to act in those fields. They would not act as to those activities which are presumed to lead to the use of space for national defense.

I interpret "presumed to lead" as meaning of likely use at some time for national defense; as perhaps a rough equivalent.

Mr. JOHNSON. Yes.

Mr. KEATING. Name any space activity, if you will, which would not fall in the category of being presumed to lead to the use of space for national defense.

Mr. JOHNSON. Yes; I agree. You come right to the heart of the problem.

If we presume that a man is going to go into space someday for military reasons, then everything that we learn about space has an impact on getting that man there. The cosmic-ray experiments now taking place as purely scientific for the IGY period are obviously very important.

As you read in the newspapers over the weekend, the cosmic-ray activity is far greater than scientists had expected at very high altitudes.

This knowledge, of course, is necessary if we are going to put a man up in space. We now know you have to shield him probably to a greater degree than we thought. There are many other phenomena associated with space travel that need to be investigated.

Therefore, if you assume that militarily someday it may be necessary to put a man in space then every bit of scientific data involving space has a long-term military connotation.

Mr. KEATING. And don't let me create the impression with you that this line of questioning is critical of you.

I admire you for saying what you think are the facts here and for being as helpful as you can to this committee.

But I want to get your thinking on this. Is there any area of space activity which in your judgment could not reasonably be interpreted by a person as being presumed to lead to the use of space at some time for national defense?

Mr. JOHNSON. I think that is correct.

Mr. KEATING. So that it follows from that, like night follows day, that if the Department of Defense did not request this Agency to act in any field, the Department of Defense would have the sole authority for space research?

Mr. JOHNSON. No. I think this independent agency, this civilian agency, could act on its own to cover fields of science which the military people in time sequence thought less important.

Mr. KEATING. In other words, that were not going to lead to the use of space for national defense in, let us say, the next 5 or 10 years, something of that sort.

Mr. JOHNSON. It could be. Actually I would envision a civilian agency planning for men in space as well. I would guess that the day will come when there will be transportation in space for exploration reasons, for reasons that we travel here on earth in space. And there could be parallel work going on.

Time phasing for military and civilian use might be quite different. Also the scientific fraternity may want to know about phenomena now that the military would want to know in the next several years.

Mr. KEATING. But if they were to have parallel authority, we could not, could we, word this in the way which you have suggested, that it would be in the hands of a civilian agency, except those things presumed to lead to the use of space for national defense, in which case they would only act upon request of the Department of Defense.

Wouldn't that, worded in that way, lead to the determination solely by the Department of Defense as to whether it was presumed to lead to the use of space for national defense?

Mr. JOHNSON. I think I said earlier that my attempted language here was maybe amateurish. I do not intend that in the language in the recommendation I made. I believe if that attempt is there, that ought to be modified accordingly.

I believe there should be separate activities, unrestricted activities, except for budgetary reasons.

I believe the two agencies should be encouraged to work cooperatively, to prevent duplication, which I think can be done.

My intention here was to make sure that the military problem was recognized and they could act speedily in military exploration.

Mr. KEATING. We, I am sure, share your feeling and concern regarding that. And we are grateful to you for presenting specific language. That is helpful to the committee.

But I would be worried by the use of those words "presume to lead to the use of space for national defense" unless this committee was prepared, as I doubt that it is, to leave the entire determination in the Department of Defense. And it is not your intention that this determination should rest entirely with the Department of Defense?

Mr. JOHNSON. Definitely not, sir.

Mr. KEATING. Did I understand you to say you would have this reentry problem licked in the year 1959?

Mr. JOHNSON. I think we can say so far as ballistics missiles are concerned we have the reentry problem licked now. And I would predict that in the year 1959 reentry from a satellite will be licked as well. It is not as difficult a problem as we thought a year ago.

Mr. KEATING. Well, did you mean by that reentry of the human, of a living animal?

Mr. JOHNSON. No; I meant only the reentry of a vehicle.

Mr. KEATING. When do you expect to have the problem licked of reentry of a living organism?

Mr. JOHNSON. A living organism?

Mr. KEATING. When are you going to get them up and bring them back alive?

Mr. JOHNSON. We definitely have plans to get this licked within the next 18 months—a living organism.

Mr. KEATING. Will that be a mouse?

Mr. JOHNSON. I have heard there have been some mice in experiments recently. My own reaction is that you would learn very little from animals of that kind. It seems to me that the real worthwhile experiments would be from chimpanzees.

Mr. KEATING. And there will be experiments with animals prior to human?

Mr. JOHNSON. Yes; certainly. And those experiments will be delayed until we are quite sure that the safe reentry of the animals can be made.

Mr. KEATING. You have got some volunteers of human animals but you will have to draft these other creatures.

Mr. JOHNSON. Correct, sir.

Mr. KEATING. You have made a very interesting line of demarcation which I understood to be the suggestion that the military have jurisdiction as far as the moon and the civilian space agency from there on out.

Was that an oversimplification of your suggestion?

Mr. JOHNSON. Yes, sir; I suspect it was. What I meant was that at the moment I would guess that the military would have very little reason to conduct scientific experiments in the neighborhood of Mars and Venus. The civilian agency would very definitely, I think, be interested in those experiments soon. And I would guess that we could probe Mars and Venus within the next 3 or 4 years.

25973—58——76

But in the meantime I think ——

Mr. KEATING. When you say "probe," do you mean in the manner in which we plan to probe the moon, by taking pictures?

Mr JOHNSON. Yes; I think that is something within the foreseeable future, but I don't believe that is a military-scientific effort in this time span. On the other hand it is entirely conceivable years from now that the interest in the area this side of the moon might be of equal concern for military reasons beyond the moon. It is a matter of timing.

This is why I feel also a civilian agency could very well complement and supplement the military work.

Mr. KEATING. Now up as far as the moon, 240,000 miles, you look upon it as primarily a military problem? Would that be a fair thing to say?

Mr. JOHNSON. I don't think that is quite fair. I think between here and the moon that there are things that the military must know more about and must have a program to know more about in order to be sure that we are not caught unawares by a scientific breakthrough or a scientific help that would produce instruments of warfare that could be used against us.

The CHAIRMAN. You don't mean that from the earth to the moon is a military area; do you?

Mr. JOHNSON No; I didn't mean that. I was trying to be very specific there.

I certainly don't. I believe there are many things we want to know about that area. But I do think that the military people must learn a lot about it too.

Mr. KEATING Well, Mr. Johnson, will you name an area of space activity between here and the moon which could not fairly be said to be presumed to lead to the use of space for national defense?

Mr. JOHNSON. I think that is right. I think that we could presume that national defense will be involved——

Mr. KEATING. In anything between here and the moon?

Mr. JOHNSON. In anything between here and the moon ultimately, yes. I sincerely believe that.

Mr. KEATING. So that under this language—and I realize that you are not wedded to it—but under the suggested language, anything between here and the moon would be governed by the Department of Defense unless they requested the civilian agency to handle it; wouldn't it?

Mr JOHNSON. No, that was not the intention. I certainly withdraw the language if that is the interpretation.

I believe that a civilian agency and the military both would have parallel paths of exploration in this area between here and the moon. I think the military obviously must have a free hand in this area.

Mr. KEATING. Perhaps instead of the words "if so requested by the Department of Defense" we should say, "If so determined by someone at a Cabinet level" or "by a Cabinet determination," or something of that kind

In other words, not leaving the matter solely in the hands of the Department of Defense. It is your contemplation that there would be areas of possible dispute which would have to be resolved by higher authority; isn't it?

Mr. JOHNSON I would agree with that; yes.

Mr. KEATING. You have been in communication with the present NACA and have been in considerable conferences about division of projects to date.

Mr. JOHNSON. Correct, sir.

Mr. KEATING. What are the natures—I don't want to ask anything I should not—but what are the natures of the projects which are in, you might say, considerable dispute between you as to who should handle it?

Mr. JOHNSON. The two basic areas that are in dispute are the man in space, which, as I pointed out, is very fundamental to the issue, and we have agreed to compromise that.

We have agreed that NACA, and the Department of Defense would have a joint program of man in space. We would fund it equally on a 50-50 basis.

The CHAIRMAN. I think that agreement is a commonsense one. I wouldn't call it a compromise. I would say that a joint program is a recognition that both were interested. And to prevent duplication and all the other things. I wouldn't call that a compromise. I would call that a commonsense decision.

Mr. KEATING. Well, it is the type of compromise preferably called commonsense decision which the members of political parties engage in in Congress from time to time.

Mr. JOHNSON. I did not use "compromise" in the negative sense. But I think it is a very sound approach.

And the other area that is in dispute is the area of a million pound or greater thrust engine where there is not now, today, a military need for an ICBM engine to give that thrust. We don't need that to go 5,000 miles, to deliver the warhead that we want to deliver. So that, too, will be a joint effort. And we are funding that on a 50-50 basis in this proposal.

Mr. KEATING. You have agreed upon it.

Mr. JOHNSON. Yes, sir.

The CHAIRMAN. What thrust is deemed necessary to deliver a continental ballistics missile 5,000 miles?

Mr. JOHNSON. Three hundred and fifty-thousand pound thrust.

The CHAIRMAN. How far have we gone now?

Can you give that information?

Don't answer any question that is classified.

Admiral CLARK. May I provide that answer to you later?

(The answer to the above question is classified.)

The CHAIRMAN. Yes.

Mr. KEATING. So that in both of these two areas which have been in dispute, you have reached an agreement with the present NACA organization.

Mr. JOHNSON. Yes, sir.

Mr. KEATING. For joint participation in these two programs?

Mr. JOHNSON. That is right, sir. And we are working together very well. The Department of Defense and the NACA has had a wonderful record for working relationships. I see no reason why the present management should not continue that kind of a relationship. We are not crticizing that. We think it is fine.

The CHAIRMAN. Of course their jurisdiction was more limited in the past than it will be under any new agency.

And that has to be considered.

Mr. JOHNSON. This is the whole problem, yes. The NACA of the past will be gone when this legislation is written.

The CHAIRMAN. The NACA was more a service agency for others.

Mr. JOHNSON. That is right, sir.

The CHAIRMAN. Now under this new agency it will not, at least in part.

Mr. JOHNSON. They will be an operating agency with power and control.

Mr. KEATING. Now there are presently, then, no major projects in dispute between you as to who should handle them.

Mr. JOHNSON. No, sir.

Mr. KEATING. And there are some which they recognize clearly as being purely military and some which you recognize as being purely civilian.

Mr. JOHNSON. That is correct, sir.

Mr. KEATING. Plus these two where you have devised the plan on divided authority.

Mr. JOHNSON. That is right, sir.

Mr. KEATING. Among those which the military has agreed are purely civilian and will be handled solely by them, could you tell us just what those are?

Mr. JOHNSON. Those that are purely civilian are a number of satellites—we will use the Jupiter—one of which will be a—well several cosmic ray experiments.

There will be one large balloon put into orbit. There will also be three lunar shots by the Air Force using a Thor-Vanguard setup, and then we are planning a follow-up program for fiscal 1959, that would involve another $45 million to $50 million of satellite launchings, the payloads of which have not been determined.

However the scientific groups would have an opportunity to recommend the next kinds of data that ought to be put into orbit to learn more about this phenomenon.

This program would really be scientific satellite launchings amounting to some $72 million or $75 million. Beyond that there would be certain work started on new kinds of instrumentation, new kinds of power sources that would be needed to travel to Venus and Mars. We need to have much more work on ion engines, for example. But placed in space they could power very large masses; get their energy from nuclear power, solar and other sources.

There is fundamental work needed for transportation in space. There is much work which can be considered right at the moment largely civilian.

Mr. KEATING. And those projects which you have just now outlined, it has been agreed between the military and the present NACA organization, would be handled by the civilian Space Agency.

Mr. JOHNSON. Yes. We are in agreement completely on the total space program. The two budgets total something over half a billion dollars for 1959. They are not approved as yet, obviously. We are in complete agreement on the total spending of that money by projects.

Mr. KEATING. That is all.

The CHAIRMAN. Mr. McDonough.

Mr. McDONOUGH. Mr. Johnson, on the projects that you have agreed to work independently on, although cooperatively, I would say—is that proper to say that?

Mr. JOHNSON. Cooperatively, yes.

Mr. McDONOUGH. There is certain basic research that is involved in the development of both of these projects, various projects?

Mr. JOHNSON. That is right, sir.

Mr. McDONOUGH. Which Agency do you look to for development of basic research on the projects that you consider military and the basic research that the civilian agency considers civilian?

I mean we should certainly come to some understanding about no duplication of basic research. Let it funnel through from one source, as much as possible.

Mr. JOHNSON. I think we have here a time problem. The basic research that a civilian agency would want now might be different from what the military would want now; depending on the objectives of that research. I think they both want the same data, but they may want it in different time periods. And this is the kind of a problem that sometimes you may not be able to resolve cooperatively.

And, therefore, each may go on his own to secure certain basic research data in a different time period.

Mr. McDONOUGH. Then if the basic research is developed and implemented by the civilian agency that will be beneficial to the military, it will be at your beck and call when you need it, and vice versa?

Mr. JOHNSON. That is right, sir.

Mr. McDONOUGH. So there would be no duplication, then, to any large degree, although probably a scientist in your group might be figuring on the same thing that a civilian scientist might be figuring on. But as far as implementation is concerned, there will be an effort to prevent duplication.

Mr. JOHNSON. That is right, sir. I think you could grasp some different concepts. Admiral Clark mentioned this morning that medicine's contribution might be very great in what we have learned in weightlessness. It may well be that certain diseases might be studied in a weightlessness concept and get some different answers.

Now, I don't think the military would be interested in that, immediately, that is, for a military objective. I am sure they are academically interested. But I mean as a military objective.

Mr. McDONOUGH. Of course that is a matter of opinion. Weightlessness, it seems to me, would be a very vital thing to the military now.

Mr. JOHNSON. Weightlessness itself is a very vital thing. But I mean in reference to studying a given disease.

Mr. McDONOUGH. Oh, I understand.

Now, insofar as the projects that are under the jurisdiction of ARPA—is X-15, one of those?

Mr. JOHNSON. No, sir; X-15 has not been considered to be an outerspace project. It gets into outer space for a few minutes at a time. That is all.

Mr. McDONOUGH. What is your understanding insofar as to which of the two agencies should spend the most time on basic research for nuclear-powered spaceships.

Mr. JOHNSON. I think there too, at the beginning nuclear-powered spaceships should be a joint effort.

Mr. McDONOUGH. That will be joint between the two agencies, plus the Atomic Energy Commission.

Mr. JOHNSON. Yes; certainly. The ion engine that I referred to is under study now in the Department of Defense in cooperation with AEC. And I suspect a civilian agency would interest itself in it.

Mr. McDONOUGH. The 350,000-pound thrust to deliver a warhead 5,000 miles, being one-third of the proposed 1-million-pound thrust, if you had 3 of those motors, you could equal a million.

Mr. JOHNSON. Yes.

Mr. McDONOUGH. It is a question of efficiency, whether it is more efficient to have 3 than 1.

Admiral CLARK. The third of a million thrust we are talking about, that third of a million is made up of three smaller engines. We do not have an engine of 350,000 pounds thrust in this country. The largest engines are the type in the Atlas missile. And these are a combination of lesser engines. I suppose you could add more. Instead of having 2, you would have 3, 4, or 5.

Mr. McDONOUGH. You would have a very big base if you did that.

Admiral CLARK. That is correct.

Mr. McDONOUGH. Is it classified as far as this testimony is concerned as to what is the maximum thrust engine we have?

Mr. JOHNSON. A single engine.

Mr. McDONOUGH. Yes.

If it is classified, don't answer it.

Admiral CLARK. I would rather provide that later, sir.

(The answer to the above question is classified.)

Mr. McDONOUGH. Very well.

Now, on the project Rover, is that part of your jurisdiction, Mr. Johnson?

Mr. JOHNSON. No; it is not, sir.

Mr. McDONOUGH. That is still a military reconnaissance project; isn't it?

It is projected for that purpose, or anticipated to be.

Mr. JOHNSON. I am sorry; it is in the Department of Defense, but it is not assigned to this Agency, ARPA.

Mr. McDONOUGH. What about Dyna-Soar?

Mr. JOHNSON. Dyna-Soar is not assigned to this Agency either.

Mr. McDONOUGH. What is in your Agency?

Mr. JOHNSON. Outer space.

Mr. McDONOUGH. Well, these are outer space projects. What do you have off the boards in the implemental stage or operational stage that would give us some idea of how far you have progressed on outer space development.

Mr. JOHNSON. The most active project is called Pied Piper. WS 117-L would be the broader connotation. That is the very large thoroughly integrated, reconnaissance satellite system, military weapons system. It is a complete concept.

It may well be man operated. But in the original concept it is not. But as we get more information on how to get a man there, I suppose it will be man operated.

Mr. McDONOUGH. How far has Pied Piper progressed?

Mr. JOHNSON. Very well. The rate of expenditure we are planning for 1959 will be triple the amount in 1958, in money and that reflects I think the progress and effort.

Mr. McDONOUGH. Well, how far has it gotten to the point where it can get off the ground?

Mr. JOHNSON. Well, test firings will start this fall. The first preliminary firings that will lead to a full-blown reconnaissance satellite being airborne. This is phased over a period of several years. The first test firings will take place this fall.

Mr. McDONOUGH. What basic thrust engine are you using on that?

Mr. JOHNSON. I think we are getting classified now. We can supply that for the record.

Mr. McDONOUGH. Mr. Johnson, I realize that you have coordinated the efforts on the missile program in your new position, comparatively new—How long have you been there now?

Mr. JOHNSON. Officially since April 1.

Mr. McDONOUGH. Yes; that is a short time. And I realize that we have a stepped-up program that we must meet in order to put ourselves in a position of competition. You may have been asked this question before.

Do you think we are moving fast enough on the program? Are you anxious to move faster?

I am speaking both of manpower under your jurisdiction and the industrial know-how in the field to build the hardware to your specification.

Mr. JOHNSON. I believe the effort we have projected in our 1959 budget is a good effort. I think we will get our money's worth. I do wish we had the money now. I could use some of it this month in letting contracts.

On the other hand I don't think we are going to lose much time by waiting until the Congress approves the budget. We are starting very rapidly with a very high caliber of scientific talent. We now have aboard some dozen men who are highly qualified in the space field, and 4 of 5 of them have doctor's degrees. We are staffing with an additional 15 to 20 scientists, and this will be complete, we think by the end of July.

Well, we will have a capability to, I think, submit in fiscal year 1960, an even better budget, with an added tempo that will encompass even greater vision in the opportunities.

Mr. McDONOUGH. You are operating on a fiscal year at the present time.

Mr. JOHNSON. Yes. You see, we are operating on the 1958 supplemental which gave us only $10 million. And that $10 million was just a downpayment on these lunar-probe shots.

Mr. McDONOUGH. Do you think you should be given the same authority on the new year budget as this bill provides for the civilian agency?

Mr. JOHNSON. Yes, sir.

Mr. McDONOUGH. Then you can move faster.

Mr. JOHNSON. That is correct, sir.

Mr. McDONOUGH. Well, as to the industrial response to your demands, are they moving fast enough?

Mr. JOHNSON. I think this is a very wonderful thing, the way industries are speculating with their own money, dreaming and thinking in outer space. I have personally listened to presentations of top men in, oh, I would guess 25 corporations who have submitted programs that literally must have cost millions of dollars to prepare out of their own funds.

I think we have, for example, on man in space over a hundred proposals, somewhere in Washington. Three or four, I think, are tremendously impressive as being realistic, as having been completely thought through. And I believe if we do get a man in space, which I hope would happen 30 months hence, it will be very importantly a contribution of American industry that got us there.

Mr. McDONOUGH. Do you have any opinion as to why, up to now, Russia hasn't done anymore than to put two satellites into orbit?

Mr. JOHNSON. I have only an opinion, which can't be verified. I think they do not have the guidance, the electronic knowledge that we have. I think they do have very definitely a thrust engine greater than ours. They were able with a single stage to put a very large object into orbit, a low orbit. I do think they intended to return the dog. I think they ran into trouble with their guidance. And I don't believe that they have solved their guidance. I feel that they must have been trying to probe the moon. I think their failure to do so by now must be guidance reasons. This is purely an unscientific opinion of a man who has only been on the job a few weeks. We know they have had failures.

Mr. McDONOUGH. You mean since the second satellite went up?

Mr. JOHNSON. Yes.

Mr. McDONOUGH. That is all.

The CHAIRMAN. Mr. Ford.

Mr. FORD. Mr. Johnson, as I analyze your testimony, it seems to me that your views indicate no desire, on the part of the military, to preempt the space field. But at the same time you don't feel a civilian agency should have the ultimate veto of any programs that the military wish to undertake in this area.

Is that a fair summary of your view?

Mr. JOHNSON. That is exactly, sir. If I could be permitted I would like to amend my testimony this morning as a result of the questioning today to make my position on a question you have asked quite clear.

Mr. FORD. Would you like to read this or would you just prefer to have it inserted in the record?

Mr. JOHNSON. I would like permission to read it.

Mr. FORD. All right.

The CHAIRMAN. You have the permission.

Mr. JOHNSON. With the indulgence of the committee I would like to make an amplifying and clarifying statement as a result of the questioning this morning.

The earnest and sincere desire of this committee to prepare legislation on space matters which will be to the maximum benefit of the United States is very clear indeed, and I want to be sure that my opinions on the subject are absolutely clear.

First, I do not presume to tell this committee how the legislation establishing NASA should be written. The purpose of my suggested rewording this morning was simply to highlight the importance of wording the bill so as not to put the Department of Defense out of business insofar as space research and exploration is concerned. I believe there should be a civilian agency for the purpose of making NACA even more effective than it has been in the past, but I do not believe that it should control or dominate space research and exploration in the United States.

Second, in the matter of NASA relations with ARPA, the discussion this morning revolved entirely around the question of what is defense research and what is civilian. While this is a knotty question, a more troublesome one has been overlooked.

Other than Vanguard, which is a low efficiency booster, the only large rockets available to launch satellites are weapons, and will be for some years.

The question then comes down not to who will conduct the experiment, but whether it should be conducted at all, since it uses up one or possibly several weapons. It means, of course, that each satellite launched must be of maximum productiveness and the experimentation to be conducted should be most carefully planned by all agencies having an interest.

It is believed in planning tests where the vehicles and money are not unlimited that considerations of contribution to national security should be paramount.

Mr. FORD. It seems to me, Mr. Johnson, that this addendum to your original statement puts this whole problem on a very practical basis. I cannot visualize any space experimentation in the foreseeable future that would not rely almost entirely upon hardware which the military has developed and is now using for its own operation. Is that correct?

Mr. JOHNSON. That is right, sir. A million-pound-thrust engine, if we put all the research of the country behind it, would probably be 5 years away, and this would be the only vehicle that could be used other than the rockets we now have.

In the meantime our own rocketry in a military sense is improving in efficiency. And to the question asked earlier, I suspect a military rocket of a million pounds thrust by combining other engines will be militarily achievable before the 5-year period. So we are faced with the civilian agency required to use military rockets to put payloads into orbit.

Mr. FORD. Assuming NASA is—it comes into being as a result of enactment of legislation by the Congress, I believe it might be well if you could put on the record how you think the 2 budgets for the 2 might be evolved; and then we can see how they would eventually come to the top of the executive branch of the Government for approval or disapproval.

Could you give us some idea how that process might work.

Mr. JOHNSON. The process is working now. We received a letter from the President, a joint letter addressed to the Secretary of Defense and to the Chairman of the Board of NACA, Dr. Doolittle, asking the two agencies to jointly get together and agree on a program, to agree on the diversion of present ARPA projects to the civilian agency when created.

And we are in the process now, as I said this morning, of transmitting a reply to this letter to the President to be signed jointly by the two agencies, giving the details of the programs of both, and the requested funding.

I think this has been a very fine piece of cooperative work. And we anticipate having—we anticipate having very little problem in getting through the executive the two budgets which will then go to the Congress.

Mr. FORD. As I understand it, ARPA's budget for fiscal 1959 is $520 million.

Mr. JOHNSON. That is right, sir.

Mr. FORD. Of which $72 million is potentially the budget for NASA?

Mr. JOHNSON. I would like to amplify that. We, in our budget, intended from the beginning that $72 million be scientific research. And this automatically would be transferred to this agency.

In addition to these cooperative programs that I have referred to, we would transfer $23 million of our money for joint programs.

Mr. FORD. Out of your proposed fiscal 1959 budget there is $72 million, plus $23 million which will be under their cognizance?

Mr. JOHNSON. That is correct, sir.

Mr. FORD. The remainder would be under ARPA's jurisdiction?

Mr. JOHNSON. Well, as I pointed out, sir, of the $520 million, $157 million is not space. The $157 million is the defense against the ICBM. So, we subtract $157 million from the $520 million, and we would get the space budget.

Mr. FORD. But then in addition, NASA will have funds of their own which it will request from the Congress separately.

Mr. JOHNSON. That is right. They have a going rate now for the work engaged in. And this submittal would request additional funds for space beyond the $72 million, or $95 million, which would be transferred from us.

Mr. FORD. There may be some concern about the possibility of duplication of effort. That can be avoided by the proper putting together of your budget and their budget and the comparison between the two at the working level.

Certainly that is what you envisage, is it not?

Mr. JOHNSON. That is right.

Mr. FORD. I can't imagine the Bureau of the Budget authorizing a budget request for the two agencies that would involve similar projects in both money requests.

Mr. JOHNSON. I think that is right.

Mr. FORD. In the early days of the Atomic Energy Commission—and I think the figures have been indicated that about 85 to 90 percent of AEC's budget was for military purposes.

Today the emphasis is going away from the military into the civilian, although still a large part of AEC's budget is military.

Would you say that under the current programs for ARPA and NASA that about the same ratio—80 or 90 percent—would be military in fiscal 1959?

Mr. JOHNSON. Well, it gets back to what is military and what is civilian. And it is so hard to draw this line.

As I said earlier, if a man in space has a military need, then everything we learn about space is knowledge that we would apply to successfully putting a man and a military vehicle in space, including cosmic ray studies.

On that concept, then everything is military.

I think this matter of definition of what is military and what is civilian is almost impossible to make.

The CHAIRMAN. Will the gentleman yield there?

Mr. FORD. Surely.

The CHAIRMAN. I suppose in answering that question that you have distinctly in mind that if we were living in a world of peace that was much easier. You are thinking in terms of the world today?

Mr. JOHNSON. That is right.

The CHAIRMAN. And the exigencies that confront us.

Mr. JOHNSON. This is my only concern. I wish, too, that this could be all civilian and the military put out of business.

Mr. FORD. The practicalities of the situation do not permit such a condition at the present time.

Mr. JOHNSON. That is right. And as I said this morning, the concern I have is that, because of our fear of the unknown, because we wish outer space not to be a military area, that we then attempt to by language or by setting up agencies to make this civilian—I don't think this will happen.

Mr. FORD. Perhaps Admiral Clark can answer this question.

From time to time in this committee, Admiral, we have had some discussion as to the rate of expenditure in new projects in research and development that eventually led into procurement of hardware.

Can you think of some project that you had cognizance of from its very inception and indicate to the committee how much was spent in the first year or so in the way of research and development and then how the buildup took place as you moved along in succeeding years?

Could you take a concrete example and give us some idea of how that process works?

Admiral CLARK. In the first 5 or 6 years the guided missile program of course, all funds expended were research and development funds.

Not until 1955 or 1956—I am talking about the Navy—did we begin to put weapons actually in the field. To put an actual percentage of dollars on it is difficult, Mr. Ford. At one particular project we had about $500 million before we got into hardware. And now it costs on the order of $25 million to buy the missiles for one ship.

Mr. FORD. How much was expended, for example, in the first year on the Polaris system? This is at the research and development stage? It was relatively small sums compared to what is being spent now? Could you give us some idea?

Admiral CLARK. I can only give you approximations. But I cannot remember the figures exactly.

The first year of Polaris, the research and development was, as I recall, on the order of $18 million. The next year it was $65 million. And this year I believe it is the order of $112 million.

Mr. FORD. I think that is a good illustration. In other words, the first year, research and development of the Polaris system was about $18 million. The second year, $65-some million. And the third year, about $112 million?

Admiral CLARK. Yes.

In this connection, if I may have a minute or so, I would like to discuss this matter of duplication.

It is in the early stages of these programs where duplication is desirable. Multiple approaches to the component question are desirable. This is your assurance of success later on.

As time goes on, you can eliminate some of the more unproductive approaches.

Where we have duplication that is bad duplication is when we have multiple weapons systems in the final system.

But to have a number of research activities working on basic activities or researching components, this is one way to assure success in a reasonable time period.

The Russians, I believe, started centralizing research and development along this line early. And it was not long before they found out that this was the wrong approach.

I believe now they have something like 700 institutions that are doing research.

Mr. Ford. That is all, Mr. Chairman.

The Chairman. I have been studying this proposed amendment that you have suggested. You indicated in response to questions that I asked earlier in the morning that in support of the use of space for national defense—I will leave out the words "are presumed"—but that is broader than the words used in the bill—"primarily associated with weapons systems or military operations".

Mr. Johnson. That is the intent—to make it broader, yes, sir.

The Chairman. The reason for that is that there may be activities in connection with the national defense other than—important and vital as they are—weapons systems or military operations.

Mr. Johnson. It is very late in a research program that you can visualize a weapons system. Once you visualize a weapons system, it is no longer research. My plea is that the Department of Defense be permitted research in these areas as they are permitted research in other areas that may have a military-science implication.

The Chairman. In other words, it is felt that in the world of today it is better to use the broader language than to use language that might be construed as covering a more limited field and really constitutes national defense?

Mr. Johnson. That is right, sir.

The Chairman. Now, it says "or presumed." I realize it is hard and difficult for you to give a definition of the word "presumed" as used in the amendment. But "presumed" might be just a person's opinion or thoughts.

Now, a determination is different from a presumption. "In support of" or "that is determined will lead to the use of space." There is a determination there by either the Director, the new Director, yourself, or the Secretary of Defense; in other words, there has got to be a determination.

Now "in support of" is one thing. Or "presumed" or "that is determined that it will lead to the use of space for national defense"—of course, the words "for national defense" are words of limitation and direction. We understand that.

Mr. Johnson. I think the basic problem there is that it would be almost impossible to determine in advance. Again a matter of judgment will always be involved in this area. I would rather err on the side of judgment that was incorrect occasionally but make sure that no opportunity was overlooked for defensive reasons than to restrict that language to a determination. Because if that determination was made outside of the Department of Defense without all the knowledge that the Defense Department has, it might be the wrong determination.

The Chairman. Of course, my question presupposes that that determination under this language would be made in the Department of Defense.

Mr. JOHNSON. Oh, then I would have no objection whatsoever; yes, sir.

The CHAIRMAN. Because it says "insofar as such activities may be in support of or presumed to lead to the use of space for national defense."

So that determination would be made, it would seem to me, in the Department of Defense.

Mr. JOHNSON. Well, if one made that assumption, then I think the language would be fine.

The CHAIRMAN. I am not saying that I—I am just exploring for the consideration of the committee later when we get into executive session. Because we have problems, as you know, beyond this committee.

Mr. JOHNSON. I understand, sir.

The CHAIRMAN. When we report a bill in the House, somebody will ask me what does "presume" mean. I have a lot of difficulty answering that. It leaves us more or less in the field of speculation.

And the committee would be vulnerable to attack. And "that is determined"—those words are plain. I assume by the word "presumed" that is what you mean—that is determined. Because that word "presumed" is not connected with "in support of."

"In support of" is one thing; "that will lead to the use of space" or "presumed to lead" is another thing.

Mr. JOHNSON. I agree with you.

Your connotation is correct. This would be self-serving; that the Department of Defense would so determine. That is correct, sir.

The CHAIRMAN. Then if the committee should in its wisdom—and I am not saying that I would be for it—I am just exploring—yet, I recognize the importance of the military in the world of today. And you say if we are going to err in judgment; I would go further, and say that if I am going to err in judgment I would rather err on the side of strength than weakness.

I have said that repeatedly before the House. We have to be prepared at all times, and be overprepared if we can be. But we won't go into that now.

We have to project our minds and see that this has to go through both branches of Congress. We have to come out of here with a civilian committee. And yet at the same time we have to recognize the practical situation that confronts the world of today and the word "presumed" if any member should hit upon that, why, I could imagine there would be a lot of difficulty for the members of the committee, including myself, answering that adequately where the word "determined" is used, or "decision made" or anything like that.

If we connect it up where there would be a few areas of disagreement, and it could go to the President or someone designated by him, why, nobody could object to that, that I could see.

Mr. JOHNSON. Admiral Clark and I both agree that "determine" is a better word.

The CHAIRMAN. Let me ask this of both of you gentlemen. We cannot write into a law words to meet every detail. We know that.

You have made a very fine case on something that might happen from hour to hour. What do you think of the liaison committee between this new Space Agency and the Defense and the Atomic Energy Commission where they are on a working level and they meet and they know what is going on?

Each one should acquaint the other with as much information as possible to prevent duplication of efforts and work. We expect a team. That is at least what I have in mind.

What might happen 10 years from now is another proposition. We will probably have a more peaceful world. But in the world of today we have to have the military in its proper sphere. We will not have a country, in case of war, unless we win.

What would you think of a liaison committee, sort of a working committee, that could meet as frequently as they wanted when anything arose, like in the Atomic Energy Commission.

Mr. JOHNSON. We like your idea of working very closely with the Congress. I think that bill has some safety features that are very desirable.

But there is the possibility of official committees set up by law delaying decision making. And do you want to comment on that, Admiral Clark?

Admiral CLARK. I think two different subjects are being discussed here. You were speaking, Mr. Chairman, were you not, of a committee such as our Military Liaison Committee with the AEC. That is the sort of thing you are talking about?

The CHAIRMAN. Something along that line; yes.

Admiral CLARK. Yes.

Mr. JOHNSON Oh, by all means; I like that idea.

Admiral CLARK. Yes; we feel that such a committee must be in existence We do not think that it needs to be, or should be, written into the law. As we said in this—as Mr. Johnson said in his amplified statement, the number of satellites that will be necessary to do all the exploration that we want will become quite a large number, Mr. Chairman. And these will come from the Nation's stockpile of weapons. And every one that is fired must be worked out completely to give us everything that it can.

Now, whenever a satellite is fired, we would sit right down with the NASA, with the National Science Foundation, with the National Academy of Sciences, and say, "We have a satellite here we are going to fire, what should we put in it; what should this experiment be?"

It should be a well-planned experiment to augment past knowledge, penetrate the frontiers of new knowledge, and not duplicate past work. In other words, it should be a well-planned experiment by everybody who has an interest in it.

The Department of Defense does not necessarily want the right to determine who is going to do what or determine what it should do. The Department of Defense's concern is simply that the Department of Defense not be written out of space exploration by law.

The CHAIRMAN. What do you mean by "written out"? You are not written out by this bill?

Admiral CLARK As I said this morning, the wording says that the Department of Defense will have projects that are associated with a weapons system or a military operation; that would immediately put a damper on our basic research, on our advanced research, in the fields leading up to these things, that we cannot visualize. We do not know what they are.

The CHAIRMAN. We had that in mind, Admiral. It was called to our attention by some of the previous witnesses. We had in mind some other language, including research and development, or words

to that effect. That was in mind and put before the committee. But you think your language in the proposed amendment will be better and cover the whole thing?

Admiral CLARK. With your modification. When you say "determined" is a better word, we agree.

The CHAIRMAN. Go ahead. I didn't mean to interrupt you, Admiral.

Admiral CLARK. I had finished.

The CHAIRMAN. But you think a liaison committee would be very helpful on a working level?

Admiral CLARK. It would, and I think there isn't any question but that this will be established. It is now, informally.

The CHAIRMAN. I would think, from the angle of the Department of Defense—and I would feel happier if I knew there were specific provisions for it. Then I would know the military are keeping in touch.

Admiral CLARK. Well, if you are speaking of a committee that would, in effect, provide a communications system, this we will have to do whether it is in the law or not. We could not work without it. Now, if you are talking about a committee that would have the authority to say who is going to do what, then that is something else. But I understood you to say on the working level. And that we would have to do. We just couldn't do without it.

The CHAIRMAN. It was on the working level that I had in mind. We have the Board, haven't we—the Advisory Board? It says, "At least one member shall be from the Defense Department." I am not talking about that. I am talking about the relationship with the Defense Department from day to day, keeping in touch with one another on the working level.

Admiral CLARK. Yes. And each will be very sure he knows what the other one is doing.

Mr. KEATING. You do not feel that you need, for that purpose, anything in the legislation at all? That would be an essential part of any working arrangement?

Admiral CLARK. Yes, sir.

Mr. MCDONOUGH. Is there, at the present time, a natural channel of exchange of information between NACA and the—and ARPA? Is there such an exchange of views in basic research at the present time?

Admiral CLARK. Yes, sir; almost continually. It is on an informal basis.

Mr. MCDONOUGH. Then it is a very natural thing. It does not require legislation, because it is a natural desire on the part of ARPA to say, "We have studied basic research on this particular physical implementation of something in space technology," and NACA says, "The same to you."

I notice in Mr. Johnson's statement that he refers to NSF, NAS, NASA, ARPA, and others deemed appropriate under the guidance and overall direction of the present Scientific Advisory Committee.

So, that means that there is a perfect coordination there, and the reason I wanted to emphasize and to be assured there would be no duplication on basic research is because basic research usually takes a long time and costs a lot of money. And, if a formula is found to work in the civilian agency and it is good for the military, they

should immediately report it to them. And if the military finds something—if the military finds a formula that is good to work in the other group, they should immediately report it to them.

Now, as far as building the hardware is concerned, there you get into expenditure of money in the industrial field. And it depends on, then, the ultimate use of the project for military or civilian and which of the two should write the specifications and call for the bids. Isn't that true?

Mr. JOHNSON. That is right, sir. And, of course, the problem with regard to all missiles—there are two demands for them. We do want to establish missiles bases, and missiles are wanted to fire satellites. There has to be a thoughtful program of timing, so that both can be done without impairing the work of either.

Mr. McDONOUGH. Yes. Well, I have appreciated over the years the competitive spirit between the various military branches. I have also been a little disturbed about the attempt on the part of one branch to do a better job than the other and, thereby, duplicating and overlapping many of the functions of one branch of the military service to the other.

I think we ought to get away from that kind of overlapping desire to be better than the other fellow. They ought to put the thing—they ought to sit around the table and talk it over a little bit, rather than to compete as severely as they have.

In many cases, duplicate airfields, duplicate types of aircraft, duplicate types of missiles, each one of them claiming they won the war. Who is going to deny it? They were there and shot the shots.

The CHAIRMAN. That is pretty good argument for the President's reorganization plan.

Mr. McDONOUGH. It is in that direction.

Mr. JOHNSON. This is one of the reasons for ARPA being set up; to get the conflict in space and missile defense out of the competitiveness of the three services. We are valiantly trying to do this. And one example is this: Just Friday we had the meteorological people from the three services, including the Weather Bureau, together, and we said, "Now, what do we want to do on space satellites to improve weather forecasting? Are each of you four going to set up your own satellites and go your own way?" The Lord forbid. And we talked this out.

And I suspect, as a result of this continuing meeting that will go on now between the four agencies, that we will have a program—it will not suit everybody—but we will have weather reporting via satellites that will satisfy the civilian, the Weather Bureau, it will satisfy the Navy, the Army, and the Air Force.

Mr. KEATING. Who is going to get it?

Mr. JOHNSON. ARPA.

Mr. KEATING. No. But which one of the services is going to do it?

Mr. JOHNSON. ARPA will determine that, depending upon the best boosters, the best equipment to get the satellite up there.

The CHAIRMAN. That is all right, within the Agency. You are dealing with two agencies now—one the Defense Department, and the other the new Space Agency. I will agree with you that ordinary common sense should say such a committee should be appointed. But, on the other hand, we meet stubborn-minded men in the journey of life. And, if everybody agreed there should be a liaison committee, why not specifically provide for it in the law? Then it has to be.

Mr. JOHNSON. I agree with you, sir.

The CHAIRMAN. That is all I have.

Mr. FELDMAN.

Mr. FELDMAN. Mr. Johnson, in response to a previous question, you said that—I think it was you, Admiral Clark, who said that, in order to get a ballistics missile that would travel 5,000 miles, you would have to have about a third of a million pounds of thrust.

The engine that the Russians developed in connection with the 2 sputniks, I am told, had, conservatively, between 250,000 and 395,000 pounds of thrust. And one estimate from another military source was that it had approximately 500,000 pounds of thrust.

Does that mean the Russians have a ballistic missile that can travel 5,000 miles?

Admiral CLARK. Yes; I would think they had an ICBM that could travel 5,000 miles. We have the thrust necessary for this. But we do it by combining engines. Some airplanes are 4-engine, some 2; it depends on the model; we put them together.

Mr. FELDMAN. If we have such an engine, why don't we get something up that weighs 1,100 pounds?

Admiral CLARK. I said we cluster our instruments.

Mr. JOHNSON. Sir, we have plans of getting something up that weighs more than 1,100 pounds in the not too distant future.

Mr. FELDMAN. It is one thing to plan something and another thing to get it up there.

Admiral CLARK. I would remind you that right after Sputnik I—immediately after Sputnik I, Russia promised the world a satellite a month. They haven't quite made it.

Mr. FELDMAN. Is that an official pronouncement?

Admiral CLARK. It was in the press. They announced it, officially.

Mr. FELDMAN. I am glad to hear they are not succeeding. And I hope you are right.

Admiral CLARK. They fired a much larger one than we have.

Mr. FELDMAN. You have worked closely with the NACA; is that right, Mr. Johnson?

Mr. JOHNSON. That is right, sir.

Mr. FELDMAN. NACA has a number of committees?

Mr. JOHNSON. When I say I have worked closely with NACA, I mean it has been only in the weeks I have been working with this particular project. As far as NACA, my work does not go for any long period of time. I am not completely familiar with their committee operations.

Mr. FELDMAN. Well, I am told they have five major committees. They had four until last fall. And then they created a new one in connection with space. And they have 31 subcommittees. And then they also have some panels under the subcommittees that meet on occasions.

I am told, also, that when a project is presented to NACA it starts with either one of the panels or with one of the subcommittees and then has to go through the organization before it finally gets up on top.

Do you know the timelag involved between the time that a project is first presented to NACA and a final decision is reached?

Mr. JOHNSON. No; I do not, sir. But I would guess, from using the committee-type structure, that it is quite a while. This is generally the case.

25973—58——77

Mr. FELDMAN. Now, going through these liaison committees, and a decision is finally made by the Director, if the project were one that is in controversy as to whether or not it was civilian or military in character, and there was an impasse reached, then the matter would have to be presented to the President, or a person designated by the President?

Mr. JOHNSON. That is my interpretation; yes.

Mr. FELDMAN. Now, that person, in order to be able to make an appraisal of the project, would have to study it very carefully?

Mr. JOHNSON. He would have to go through the whole procedure again: yes.

Mr. FELDMAN. That is right. He could not be enough of an expert so that, if the problem, say, involved cosmic rays, or some other highly technical problem, even though he, himself, were a scientist, he could know it all. So he would have to, in turn, have a staff which would be advising him concerning these various projects: is that not so?

Mr. JOHNSON. Certainly. If I were in that position, I would demand a staff.

Mr. FELDMAN. So what we have is another agency on top of this Agency; is that not so?

Mr. JOHNSON. Well, you would have a staff on a staff on a staff; yes. It may not be an agency.

Mr. FELDMAN. Well, it is still an agency. Whether you call it a staff or agency is immaterial.

What I am trying to get at is this: Dr. Dornberger, who is one of the elder statesmen in this field, testified here on Thursday. And he said he began in 1951 and made 678 separate and distinct presentations—separate presentations—of a project which was finally accepted in 1958.

Is this the result of this kind of layer upon layer of committee and indecision which results in that kind of a delay, and the huge amount of effort involved in getting an answer?

Mr. JOHNSON. It could be. I wouldn't know how to answer that question in this specific case. But it could be.

The CHAIRMAN. Are you familiar with the report last October of the Army scientists, the panel, Secretary Brucker's report that we have the men, the facilities, but the question is top management?

Mr. JOHNSON. No, I am not familiar with that report, sir.

The CHAIRMAN. That is in the record.

Mr. FELDMAN. Do you feel that the Department of Defense should be allowed to carry out any space projects it feels are military in character, even if they had foreign policy implications which might be important to the Department of State?

Mr. JOHNSON. Oh, no, sir. I think the National Security Council—there definitely are connotations that have to be weighed by the President and the entire National Security Council involving the Department of State and other agencies. I would not think that the Department of Defense could be freewheeling ever.

Admiral CLARK. We are briefing the Department of State tomorrow morning on a number of our projects for their education in space work, programs to be planned, and things we want to do for this very purpose.

Mr. FELDMAN. Do you feel the head of this Agency, this new Agency, should be a member of the Security Council?

Mr. JOHNSON. Are you referring to the new civilian Space Agency?

Mr. FELDMAN. That is right.

Mr. JOHNSON. Well, I think that there would be good reasons for it. And I can think of reasons against it. Because policymaking at that level cannot involve too many people, too many agencies and too many viewpoints.

I think the reporting should be made to the President; someone in the President's office would probably make the Security Council familiar with the viewpoint if there was a viewpoint there to be expressed.

We would not recommend officially making them a member of the Council, no.

Mr. FELDMAN. Getting back again to this committee structure where you have, as I say, starting with a panel, a subcommittee, then a committee, then the Director or a Commissioner if you will, and then going to—having to go to the designee of the President or the Agency or the staff that would be appointed to arbitrate disputes; do you think we can afford to sit on our hands that long and wait for a decision on some important project while the Russians, of course, are going full speed ahead?

Mr. JOHNSON. No. This is really my concern. I can see in the months ahead very important decisions being made day to day.

If this were not a public hearing we could take our hair down and tell you of some decisions that are being made by the hour right now fraught with tremendous responsibility.

We are going off on a project decided in the last few days that has a 15-percent chance of succeeding. But it is so imperative to find this knowledge that we had to do some very extraordinary things even over the weekend. If I had had to stop and get a committee or someone else into the act, we would have lost very precious hours. And this is a matter of utmost urgency.

And I think more of this is going to come in the future.

Mr. FELDMAN. That is why ARPA was created?

Mr. JOHNSON. We have cut red tape and we deal directly.

Mr. FELDMAN. Which of the following projects would you feel should be controlled by ARPA and which by NASA if it is created:

1. Weather reconnaissance satellites?

Mr. JOHNSON. Weather reconnaissance has very vital connotations. Any military theater needs to have the weather forecast much more accurately than we do now. The Navy has different requirements than the Air Force. The Air Force has quite a different problem. And the Army has an entirely different one.

Now, the Weather Bureau has another problem. My guess is that to best do this job, since much military equipment will be used, that it ought to be under the supervision of a military agency.

However, I would not argue in putting it under a civilian. But my guess would be that if that were done, instead of having a minimum number of weather satellites in orbit, we might have to put a—and expensively—put up additional ones to satisfy additional military and civilians separately.

Mr. FELDMAN. No. 2. Television, facsimile relay satellite.

Mr. JOHNSON. Television could be used, of course, for cloud cover to tell us what cloud formations there were.

It could be used also for reconnaissance of another nature. I think, generally speaking, the weather reconnaissance will ultimately use television. Television is accurate—or television can accurately tell in a small area whether the clouds are rising or falling, which will be very helpful information.

I would say television would definitely be needed in military reconnaissance and will be needed also for weather observation.

Mr. FELDMAN. Three. Mapping satellites.

Mr. JOHNSON. Mapping satellites, of course, obviously have two uses. And my guess is that the greater use for the period ahead will be military. We know more about our own country than we know about other countries.

Mr. FELDMAN. Four. Manned space station. Or a large satellite.

Mr. JOHNSON. Well, I cannot conceive of a civilian need to put a man in a satellite at the moment. But I can conceive of many reasons militarily. I think this is a military program; should be a military program.

It is going to be a very expensive one. It is going to be very, very costly to put a man up there and keep him there for any period of time and do it with any assurance of success. Millions and millions and millions of dollars.

If we are going to do it through a civilian agency, it is hard to justify it.

Mr. FELDMAN. Five. Probes to the Moon, Mars, and Venus.

Mr. JOHNSON. I think we have already made that decision. For now we are conducting the scientific experiments but will transfer them to the civilian agency.

Mr. FELDMAN. Six. Manned circumlunar flight.

Mr. JOHNSON. For the moment that is also civilian.

Mr. FELDMAN. Seven. Manned round trips to the moon or planets?

Mr. JOHNSON. There I think you are coming very close. If you are operational to that, the military has got to get into the act.

Mr. FELDMAN. Eight. I have here a million pound rocket. But you answered that question before.

Nine. Nuclear rocket system.

Mr. JOHNSON. The military are just as interested in nuclear rocket systems as any possible use in a civilian setup.

Mr. FELDMAN. Ten. The Ionic rocket system.

Mr. JOHNSON. Same for that.

Mr. FELDMAN. What are the real principles that have guided these decisions that have long had ultimate military applications as well as civilian and scientific uses?

Mr. JOHNSON. We have used, I think, a formula—not an original one—but again I come back to the time span. At the moment this first basic knowledge that we are getting is purely research in character. We are saying it should be under civilian auspices, because the whole scientific fraternity is interesting themselves. The IGY program let loose a whole—literally hundreds of scientific people in the search for new data.

We want to keep that enthusiasm and that interest high. I believe that the continuation of the IGY program, which I understand has been extended for another 6 months, is a very desirable thing.

I think that sort of thing under a civilian agency ought to go on for a number of years.

Then, as this science becomes more definitive and we see the military threat—I think that is what we always have to look for—by using that science, then I think we have to do more in the Department of Defense down very special alleys. And I could talk—if this were not an open session, I could talk also about security matters and things we are learning already that very early have military problems.

Mr. FELDMAN. I think it gets back to something along the line that Congressman Ford mentioned before, namely, that there has to be a transition period. While the percentage of military activity may be great at the outset, it becomes lessened over the years, just as in the case of the Atomic Energy Commission where the development of isotopes is becoming an important factor as well as nuclear reactors for powerplants and things of that sort.

Experience teaches those things. And then, as I say, the peaceful uses become—the percentage of peaceful uses increases correspondingly.

Mr. JOHNSON. It is bound to do that here also.

Mr. FELDMAN. At least at this point, the NACA as presently constituted works primarily either for the military, that is, serves the military, or contracts with the military; is that not so?

Mr. JOHNSON. Yes, sir, it does. But the charter that set the NACA up allows that Agency to initiate work on its own.

Mr. FELDMAN. Well, I am talking about the fact, rather than what the charter says.

Mr. JOHNSON. Oh, yes, as a fact I think you are right.

Mr. FELDMAN. No further questions.

The CHAIRMAN. What kind of a man—the qualifications and so forth assuming it is an Agency with a director or an administrator—oneman agency—what kind of man do you think should head the new Agency at this time?

Mr. JOHNSON. Well, certainly he would have to be a very highly qualified man. I would say that his administrative ability should transcend other characteristics. I do not necessarily think that it would be necessary or even wise to pick the finest scientist, for example that we have in the country and put him in charge of a show like this. I think that the man has to be administratively capable with a proven record for getting things done, of planning—the planning function, particularly.

I think he has to have an understanding, however, of research and scientists in order to work with them. I think the greatest characteristic is a proven record of getting things done—cooperatively, of course, and preferably within Government.

The CHAIRMAN. Well, proven records in one situation might create a status quo state of mind as to the future, you understand.

Mr. JOHNSON. Yes.

The CHAIRMAN. Would you include in that that one must have a forward-looking, pioneering mind, and a sound refreshing dynamic outlook?

Mr. JOHNSON. Oh, you describe perfectly the other characteristics that are certainly needed.

If a man doesn't have vision and is not reaching forward all the time, he won't work. I think he ought to not be interested in operational hardware as such.

The CHAIRMAN. We could pass the best law in the world, and if it isn't administered right, why, then, it is a poor law. A law that may not be weak and may not be strong, but has flexible provisions and interpretations—with a man who has confidence in himself, it could function fairly well.

So, no matter what we do, it has to be administered through human hands. That is a question that is self-answerable.

Mr. JOHNSON. However, sir, if I may observe this: Counsel was talking about committees and panels and administrative procedure that is time-consuming. I think it is important to recognize an experience perhaps that gets things done quickly but thoroughly. This is the reason I put the emphasis on administration first.

The CHAIRMAN. I realize the significance of that. Because I understand administrators in this particular field are very few and far between. They don't necessarily have to be scientists, but have the confidence.

I understand Doctor Killian is one of those men.

Mr. JOHNSON. I think he is a very capable man.

The CHAIRMAN. We understand just what you mean, Mr. Johnson.

Mr. JOHNSON. The Chief Scientist for ARPA is in the same league. He is largely responsible for our atomic weapons—as much responsible for our atomic weapons as any man in the country.

The CHAIRMAN. I found when we had the Riehlman Committee in 1954 there were good men, fine men, dedicated men, men I respected, but there were those little clashes of personality which we all have which we have got to subordinate to the country's interest.

I attach much importance to who is going to be appointed if we establish an agency with one man at the head. Because we can pass the strongest law in the world, but it isn't going to be administered effectively unless there is a man there who has the vision and the capabilities and all the other factors that will make up—and most important among those is confidence in himself—I would rather have a man with ordinary ability but good commonsense than a brilliant man who is irrational-minded, for example, in a position of trust.

And, so, it is very important what kind of a man is appointed in the event of a one-man agency.

Are there any further questions?

(No response.)

The CHAIRMAN. You have been very patient, both of you gentlemen. And we appreciate it very much. You have given us an awful lot of information. You have been frank.

And for myself, as chairman of the committee, and for all the other members of the committee, I express to both of you gentlemen our thanks.

Mr. JOHNSON. Thank you. It has been an honor to be here.

The CHAIRMAN. The next witness is Dr. Hubertus Strughold, Chief of the Department of Space Medicine, School of Aviation Medicine, United States Air Force, Randolph Air Force Base, San Antonio, Tex. And also Col John Stapp, Chief of the Aero Medical Laboratory, Dayton, Ohio.

Have you a prepared statement?

Dr. STRUGHOLD. Yes.

The CHAIRMAN. Do you have one, Colonel Stapp?

Colonel STAPP. I have a fairly large report to come later.

The CHAIRMAN. Well, we will hear Dr. Strughold and then you can make your preliminary statement. Then we will have members of the committee ask both of you questions.

We are glad to have you before us.

Mr. KEATING. Do we have copies of the statement?

Dr. STRUGHOLD. They are available.

The CHAIRMAN. All right. Dr. Strughold.

STATEMENT OF HUBERTUS STRUGHOLD, M.D., Ph.D.,[33] PROFESSOR OF SPACE MEDICINE, ADVISER FOR RESEARCH SCHOOL OF AVIATION MEDICINE, UNITED STATES AIR FORCE, RANDOLPH AIR FORCE BASE, SAN ANTONIO, TEX.

Dr. STRUGHOLD. I consider it a great honor to appear before this committee today (May 5, 1958) to discuss the medical aspects of space flight, or astronautics. Perhaps first I should give you in a brief prepared statement an overall picture of this entire field of space medicine and astrobiology, followed by specific remarks about the following points:

1. Medical and biological research aspects of space exploration.
   (*a*) What research is being done.
   (*b*) What are the areas which need immediate and special attention?
   (*c*) How can research be improved.
2. Education in the medical and biological sector of astronautics.
   (*a*) What is the present status.
   (*b*) How can education be improved.

Scope of research.

As a logical extension of aviation medicine, space medicine studies [35] the medical problems in flight within the space-equivalent regions of the atmosphere, and [36] outside the aerodynamically effective atmosphere. They are essentially the result of the ecological milieu conditions of space and of the process of motion to, through, and return from the environment of space.

The inclusion of the environment found on other celestial bodies into space medical considerations, i. e., viewed from the standpoint of human physiology and survival requires careful studies in planetary ecology in advance. This astromedical study overlaps with astrobiology which concentrates upon the question of indigenous life on other celestial bodies. All these various studies represent specific aspects of a more general field which can be called bioastronautics.

Originating about 10 years ago, space medicine has made considerable progress in the United States theoretically and experimentally

[33] Strughold, Hubertus, physician, educator, b. Westtnennen, Germany, June 15, 1898; s. Ferdinand and Anna (Tillmann) S., student U of Muenster, 1919–20, U. Gottingen, 1920–21, U. Assn., of Am. Aeromed. Assn., 1951–52. Author· Grundrisseder Luftfahrtmedixin; Space Medicine (coauthor). Contbr. articles on physiology, aviation medicine and space medicine. Address· U. S. Air Force School of Aviation Medicine, Randolph Field, Tex.

[35] Atmospheric range from about 12 to 120 miles.

[36] Atmospheric range from above 120 miles.

in the laboratory and in flight operations. In the U. S. S. R. the literature in "cosmic medicine," as space medicine is called, follows very closely the line of thinking of the West. For several years the Russians have stood on their own feet, and the progress made by them is evidenced by animal experiments in rockets, and by Sputnik II. In 1947 the Russians founded a department of astrobotany.

After this brief introduction, the following comments are made.

1. MEDICAL AND BIOLOGICAL ASPECTS OF SPACE EXPLORATIONS

(*a*) What research is being done? A great deal of research has been devoted to human engineering of the space cabin as carried out in space cabin simulators. These studies concentrate upon the question of the best suitable artificial atmosphere, and of the most effective air regenerating devices.

Methods for recording the climatic conditions in such closed ecological systems and for recording the physiological reactions are being developed. For the past 5 years the inclusion of plants in a closed ecological system as oxygen producers and carbon dioxide absorbers has been under study at various places. The effect of increased g. forces upon the human body is pretty well understood due to studies on centrifuges and on sleds. Zero gravity, or weightlessness, is presently being studied during parabolic flights in jet planes concerning its physiological and psychological effects

The problem of day-night cycling in space operations has been and is being studied theoretically and experimentally in space cabin simulators. The same is true for the psychological effects of isolation and confinement.

Sealed gondolas have been tested in manned balloon flights up to 102,000 feet. One man has been kept alert in a space cabin simulator for 7 days.

The physiological effect of rapid decompression of a space cabin is well understood. Cosmic ray studies have been carried out in numerous balloon flights. In experimental astrobiology, terrestrial microorganisms have been studied under simulated Mars conditions. These are some of the most important studies that are underway.

(*b*) What are the areas that need immediate attention:

(1) Methods of rescue during the critical launching period.

(2) The problems related to reentry.

(3) Studies concerning long range straight line landing maneuvers.

(4) Visibility of the earth from great altitudes.

(5) Exposure to gravity for longer durations.

(6) Exposure to cosmic rays for longer periods of time.

(7) Simulation of cosmic ray particles.

(8) Experimentation with artificial meteorites and their impact upon a closed cabin.

(9) Search for the most effective air-regenerating means.

(10) Continuation of efforts in the development of comfortable pressure suits.

(11) Animal experiments in rockets and satellites as supporting studies for the solution of manned space operations.

(12) Interdynamic medical adaptation to space flight for selection.
(13) Experiments in multimen space cabin simulators.
(14) Telemetering as means of monitoring the space crew.
(15) All medical problems related to the time factor in flight.
(*c*) How can research be improved?
(1) By minimization of redtape.
(2) By more and better facilities.
(3) By better opportunities in the form of a sabbatical leave for scientists to visit scientific institutions here and especially abroad.
(4) By the creation of a translation and distribution center of foreign literature.
(5) By the introduction of the metric system. (The introduction of the metric system by the Russians during the October Revolution of 1917 is to a great extent responsible for their success in rocketry.)

2. EDUCATION IN THE MEDICAL AND BIOLOGICAL SECTOR OF ASTRONAUTICS

(*a*) What is the present status? For more than 5 years, space medicine has been taught in the various courses for flight surgeons at the School of Aviation Medicine, Randolph Air Force Base, Texas only.

(*b*) How can education be improved? All universities should include in their curricula several space medicine lectures per semester. Educational films should be used on a broader scale.

All pupils in grammar schools and students in high schools should be familiarized immediately with the metric system as this is the only system that—as in nuclear physics—can conveniently be used in astronautics.

In concluding this report, I should like to emphasize that all the efforts at the present time have to be concentrated on achieving a manned orbital flight in the sense of celestial mechanics. A dozen or so revolutions of such a biosatellite will reveal whether or not man can stand space flights over longer periods of time. At present it seems to me that, from the standpoint of medicine, the picture looks rosier than it did 5 years ago, but it should also be emphasized that there are limitations for space operations in our solar system. Space flight in the near and remote future will have to be confined to a certain area in our solar system. (Ecosphere=the range from Venus to Mars.)

All suggestions for operations beyond this area are not acceptable from the standpoint of space medicine and belong in the department of nonsense. For a realistic approach, factual science combined with imagination and horsesense must be the basis for planning in the exploration of space.

As a final remark I would like to add that space medical studies will be beneficial for medicine in general.

Thank you very much.

The CHAIRMAN. Colonel, do you want to make your statement now?

Colonel STAPP. Yes, sir.

STATEMENT OF COL. JOHN PAUL STAPP,[34] CHIEF AERO MEDICAL LABORATORY

Colonel Stapp. My principal concern relates to the rather limited resources for biomedical research which exists in the United States. These are concentrated in 3 aero medical laboratories in the Air Force and 2 facilities in the Navy. The Aero Medical Laboratory at Wright Field, the School of Aviation Medicine at Randolph Air Force Base, and the Holloman Air Force Base Aeromedical Field Laboratory. In the Navy, Aero Medical Acceleration Laboratory at Johnsville, Pa., and location of a modern human centrifuge, and at the Pensacola activity of the Navy in conjunction with the Navy's flight surgeon school, where cosmic radiation biological effects are studied.

This means that we have in these laboratories facilities that have been developed, special equipment for aero medical and space medical research, and a limited number of personnel that can be used effectivey in carrying out such research.

A report which I would like to have admitted to the record for later delivery concerns the resources for biomedical research available in the Armed Forces, and in particular, the Aeromedical Laboratory and the supporting laboratories at Wright Field, which constitute a very strong capability. A civilian agency requiring space medical and aero medical research would have the choice of working with these facilities without disturbing or greatly impairing their capability, or else creating laboratories of its own which could only be staffed adequately, at least in the early stages, by competing for the services or personnel in the armed service laboratories, or else by utilizing a contractor who would have no choice except to proselyte the armed services laboratories personnel

Speaking as the project officer for Wright Field's man-in-space program, we are very happy to cooperate with the civilian agency in carrying out any research problems in the area of human factors in relation to space research. In my own career I have done both civilian and military research; I find the only difference to be in the applications. The capabilities can be turned in either direction; if the military laboratories were to be limited specifically to military missions, then, a large proportion of their capability would certainly be available for work with a civilian agency on whatever problems could be agreed on.

I can see only three important military potentialities of a man in space that need exploration. First, is the capability of a man to be of any use in a boost glide or Dynasoar type of vehicle. Here it is intended to use a man in a ballistics missile for whatever guidance he can adequately provide.

(The above-mentioned report follows:)

Requested by Select Committee on Astronautics and Space Exploration

Biophysics branch

Personnel:

Field of work	Civilian	Military	Field of work	Civilian	Military
Medicine	1	10	Engineering	3	6
Veterinary medicine	0	1	Electrical engineering	6	0
Medical technology	2	0	Machinist (master)	1	0
Pharmacology	0	1	Psychologist	0	1
Biology	0	2			
Physiology	2	1	Total	20	24
Anthropology	5	0			

Facilities (major):	*Use*
(*a*) Human centrifuge (20 ft radius).	Physiological, mechanical, and some engineering testing. G-protection devices and related equipment development.
(*b*) Small animal centrifuge.	Basic research in microcirculation.
(*c*) Isolation chambers (1 large, 2 small).	Psychological and psychophysiological studies in the areas of stress, fatigue, and performance.
(*d*) Specialized medical instrumentation group.	Supports varied projects requiring highly specialized medical and physiological data recording systems.
(*e*) Downward ejection rig.	Studies of the human factors in escape from aircraft.
(*f*) Deceleration tower (under construction).	For use in testing various types of Air Force equipment (e. g., restraint systems, seats), studies of vertebral injury sustained in escape from aircraft. Equipped to record several types of physiological and mechanical data.

Research effort: Dollar value for fiscal year 1958, $713,302.
Research problems for civilian investigation: None.

Clothing Branch

1. The following research resources are available to the Clothing Branch for support of or assistance to a civilian space research program:

(*a*) *Personnel* (*all civilians*)

(1) One materials engineer (textile engineer) for establishment of requirements and applied research in the field of textiles and related materials and their application. Research and development of clothing components.

(2) One materials engineer (chemical engineer) for establishment of chemical requirements and applied research in the fields of plastics, coating, and treatments of textiles and related materials and their components.

(3) Three designers for functional, flight, and protective clothing.

(4) One designer for protective headgear.

(5) One patternmaker for making and grading patterns.

(6) Two graphics art specialists for carryout grading of patterns.

(7) Five technicians for experimental production.

(8) Five clothing samplemakers for fabrication.

(9) One cutter.

(*b*) *Facilities*

(1) Equipment to perform tests for physical and chemical material characteristics, including resistance to heat up to 3,000° F.

(2) Complete shop facilities for experimental garment production, including 50 sewing machines, electronic seam-sealing equipment, hardware installation equipment, cutting equipment, patternmaking and cutting equipment.

(c) *Dollar value*

(1) $142,724, committed.
(2) $92,000, uncommitted

Aero medical laboratory—engineering and development branch, research resources

I. Personnel:

3 General supervisory engineers	Civilian.
6 Mechanical Engineers	Do.
2 Chemists	Do.
1 Physiologist	Military.
1 Biologist	Do.
1 Chemical engineer	Civilian.
3 Engineering technicians	Do.
1 Master mechanic	Do.

II. Facilities:

Helium cryostat	Low temperature and gas properties studies.
"Norelco" gas liquefier	Do.
Rubber, fabric and limited plastic fabricator facility.	Prototype fabrication.
Oxygen generating plant (2)	Low temperature and gas properties studies.
Water test tank (40 by 40 feet)	Capsular water survival tests and submerged atmosphere tests.
Heat, cold, and low pressure laboratory test facilities.	Testing purposes

II Dollar value: Contract funds, $600,000 per year.

IV. Suggestions:

A. Suggestions as to research projects which might lend themselves to civilian investigations:

1. Project tasks:
   - Equipment for life support in astronautical operation.
   - Respiratory support equipment
   - Nutritional support equipment.
   - Refuse management.
   - Crew survival problems and equipment.
   - Integrated systems of life-supporting equipment.
2. Project tasks:
   - Life-supporting elements for space flight.
   - Composition and conversion of respiratory gases.
   - Composition and conversion of body wastes to reusable form.
   - Interaction of composite regenerative cycles.

B. Suggestion of research problems:

1. Biological gas exchanger.
2. Zero "G" oxygen converter.
3. Carbon dioxide decomposition cell.
4. Chemical respiratory closed system.
5. Hydrogen peroxide respiratory closed system.
6. Miniature feeding console.
7. Crew survival compartment.
8. Waste disposal unit.
9. Human waste water recovery unit.

Physiology Branch

A. Personnel:

	Component
1 administrator, (research and development)	1 military.
3 bacteriologists	2 military, 1 civilian.
4 biochemists	3 military, 1 civilian.
4 biologists	Do.
18 chamber operators	18 military.
2 chemists	2 military.
4 engineers	1 military, 3 civilian.
3 engineering technicians	3 civilian.
1 food service supervisor	1 military.
1 health physicist	Do.
1 home economist	Do.
1 instrument and model maker	1 civilian.
7 medical officers	4 military, 3 civilian
3 nutritionists	1 military, 2 civilian
4 optometrists	3 military, 1 civilian
1 pathologist, veterinary	1 military.
14 physiologists	6 military, 8 civilian.
1 pharmacologist	1 civilian.
3 scientific aids	2 military, 1 civilian
3 veterinary medical officers	3 military.

B. Facilities

1. Facilities for all types of human and animal physiological testing under extremes of heat, cold, humidity, and altitude as follows:

(*a*) All-weather environment chamber:

Size 13 feet by 18 feet by 10 feet high.

Capacity: 10 bench seats.

Temperature range: $-40°$ F. to $+165°$ F. (control within $\pm 3°$ F.).

(*b*) Environmental test facility (under construction).

Size: Test space 4 feet by 8 feet by 6 feet high.

Capacity: 1 subject, plus 1 observer in lock.

Altitude. 100,000 feet maximum ascent to 100,000 in 6½ minutes; descent to ground level in 7½ minutes.

Environmental capabilities:

Wall temperature. $-65°$ F. to 500° F. in 2½ minutes, 500° F. to $-65°$ F. in 5 minutes.

Air temperature: $-50°$ F. to 350° F. in 5 minutes, 350° F. to $-50°$ F. in 6 minutes.

Relative humidity: 0 to saturation in 4 minutes.

Air velocity: 50 ft./min., 800 ft./min. in 4 minutes, 800 ft./min. 50 ft./min. in 4 minutes.

(*c*) Temperature and humidity test equipment and instrumentation for recording physical variables.

(*d*) Air source for conditioned ventilating air and allied instruments.

2. Facilities for conducting biochemical and toxicological investigations involved in human factors aspects of astronautical operations as follows:

(*a*) Biochemical, clinical and toxicological laboratory.

(*b*) Pathological and histological laboratory.

(*c*) Small animal colony.

3. Altitude chambers used to investigate human responses to simulated high altitudes as follows:

(*a*) Altitude Chamber—Door 6 feet x 6 feet—0 to 100,000 feet altitude.

(*b*) Altitude Chamber—Door 2½ feet x 6 feet—0 to 70,000 feet altitude $-65°$ F. to $+160°$ F.

4. Isotope laboratory contains facilities and instrumentation to conduct isotope studies involved in physiological and biochemical investigations.

5. Nutritional Assay Laboratory. This laboratory contains standard biochemical apparatus, including the following items: fume hood, Kjeldahl nitrogen apparatus, fat extraction apparatus, analytical balances, oxygen bomb calorimeter, muffle furnaces and vacuum oven, gas analyses apparatus with meter, refrigeration equipment, autoclave, centrifuge, spectrophotometer, pH meter, water distilling apparatus, and allied equipment. This equipment will support a program consisting of basic nutritional and biochemical factors relating to inflight and space feeding.

6. Microbiology and Cellular Physiology Laboratory. This laboratory contains standard micro-biological apparatus, including the following items: Aterile hood (for tissue culture), fume hood, Warburg, refrigerated and nonrefrigerated centrifuge, incubator, autoclave, freezer, pH meter, analytical balance, spectrophotometer, microscope, and other corresponding equipment. This laboratory, as it is presently equipped, supports all microbiological and tissue culture requirements for the study of space environment and space feeding.

7. Experimental Food Preparation Facility. This laboratory is used to translate and apply nutritional requirements into feeding programs. Formulate packaging procedures. Develop storage and service techniques.

8. Bacteriological laboratories equipped to conduct studies on the vulnerability and defense of Air Force installations to bacterial warfare agents.

9. Bacteriological air-transportable trailer laboratory with facilities for BW research on pathogenic micro-organisms

10. Optical laboratory equipped for the investigation of visual problems concerned with air operations and facilities for simulating high intensity flash phenomenon involved in nuclear explosions.

C. Dollar value of contract research: $1,800,000.

D. Research projects which might lend themselves to civilian investigation:

1. Acceptance of precooked dehydrated foods Determine the effect of continuous and repetitive consumption of a limited number of precooked dehydrated foods on their preference ratings and the extent to which they may be rejected. This will involve studies of 6-month duration in which captive test subjects would be essential.

2 Determination of types and amounts of food constituents to incorporate into low-residue feeding regimens for space feeding.

3. Determination of the physiological compatability of feeding concentrated and purified foods.

4. Electrolyte and water balance studies under stresses of space environment (elevated temperatures, zero gravity, etc)

5. Development of acceptable types of feeding devices for use in space travel (under zero gravity conditions)

6 Determination of caloric requirements of man existing for varied lengths of time under space travel environmental conditions.

7. Determine the nutritional requirements under conditions of continuous low-level radiation, and the value of certain nutrients in enhancing the rate of repair from the effects of such radiation.

8 Determine the effect of continuous low-level radiation on infectivity and resistance of animal hosts and the protective effects of proteins, carbohydrates and fats

9. Determine site of action of radiation, utlizing tissue culture techniques.

10 Investigation of visual factors in air-air detection.

11. Effect of space flight environment upon the normal flora of the respiratory and digestive tracts.

12. Effect of high-altitude radiations upon the virulence of pathogenic microorganisms for experimental animals.

TRAINING PSYCHOLOGY BRANCH

1. Number of personnel identified by technical specialty and component:

	Assigned		Vacant [1]	
	Civilian	Military	Civilian	Military
Research Psychologist	13	3	10	2
Engineer	5	1	2	
Apparatus Technician	2			2
Education Specialist	1		1	
Total	19	4	13	4

[1] These vacant positions are a portion of those recently allocated to Wright Air Development Center as a result of the reorganization of the personnel and training program in the Air Force. It is expected that they will be filled by September 1, 1958. Approximately 15 additional personnel spaces will be available when the present vacancies are filled.

2. Facilities and potential uses:

(*a*) Ten small analog computers and associated equipment are available for studies to determine the necessary conditions for training, and evaluating, operators (ground and space) in the operation of precise and complex control systems.

(*b*) Seven automatic tutoring devices are available for research on more efficient ways of training maintenance personnel.

(*c*) Several experimental devices are available for studies of more efficient ways to teach personnel how to troubleshoot complex electronic equipment—such as the equipment at launch and tracking sites.

(*d*) Space for experimentation, and the multifold miscellaneous support facilities, are available for research on the necessary training conditions to support space systems.

3. Dollar value of the contract research effort:

Fiscal year 1958	$128,000
Fiscal year 1959	[1] 585,000
Fiscal year 1960	[1] 790,000

[1] Ceiling (with new responsibilities).

4. Suggestions for research projects which might lend themselves to investigation by a civilian agency:

(*a*) Determination of the training that is necessary so that a man will not panic, or perform unreliably, even under the extreme stress (or stresses) of isolation, acceleration, and unforeseen emergencies. Perhaps the studies will include the use of drugs or hypnotism to synthetically induce stresses for training purposes.

(*b*) Determination of the training that is necessary in order for a man to interpret his own physiological cues to unsafe environmental conditions, such as excess carbon dioxide, ozone, irradiated atmosphere, etc.

AIRCREW EFFECTIVENESS BRANCH, AERO MEDICAL LABORATORY (WCLDH)

1 officer, B. S. Biology, 8696, Research and Development.
1 officer, B. S. Bacteriology, 8696, Research and Development.
1 officer, B. S. Mechanical Engineering, 8636, Mechanical Engineer.
1 officer, B. S. Psychology, 8461, Research and Development Administrator.
2 airmen, 58170, Parachute Supervisors.
2 airmen, 92270A, Personal Equipment General Supervisors.
1 civilian, 8696, Research and Development Officer (Survival Equipment Supervisor).

2 civilians, 92270A, Equipment Specialists (Personal Equipment).
1 officer, M S Ichthyology, 8446, Research and Development Administrator.
1 civilian, B S Industrial Management, 8464, Engineering Technician
1 Officer, Doctor of Optometry, 8696, Research and Development Officer.
2 officers, B S Mechanical Engineering, 8636, Mechanical Engineer.
1 officer, M. A. in Psychology, 8596, Research Psychologist.
1 civilian, Mechanical Engineering, 8696, Research and Development Officer.

BIOACOUSTICS BRANCH

1. *Personnel*

The Branch is made up of 36 technically qualified persons under the supervision of a research physicist who has had considerable experience in directing research in biophysics and bioacoustics. The Branch functions as five unified multidisciplinary research teams.

(*a*) A team of 13 persons with the highly specialized capabilities for measuring, evaluating, and controlling the acoustic fields generated by missiles and space vehicles during flight and launch. Technical specialties represented on this team are as follows:

1 civilian physicist.
4 military physicists
1 civilian electronics engineer
1 military electronics engineer
1 civilian mathematician.
1 civilian mechanical engineer.
1 military mechanical engineer.
1 civilian master instrument designer.
1 civilian electronics instrumentation specialist
1 military electrician.

(*b*) A team of seven persons with experience and capabilities for investigations on the effects of large amplitude transient accelerations and impact on men and animals. These investigations include studies of the physical characteristics of the body, physiological response and psychological performance under adverse conditions. Scientific and technical specialties represented are as follows:

1 civilian biophysicist.
1 civilian medical doctor
1 military medical officer, neurophysiologist.
1 military nuclear research officer.
1 military electrician.
1 electronics engineer.
1 electronics instrumentation technician.

(*c*) A team of six persons under the direction of a senior neurophysiologist. This team possesses capabilities for conducting basic and fundamental studies on the neurophysiological properties of animal and human sensory systems. Examples of these systems are the hearing organ, the vestibular apparatus, and the central nervous system. Specialties represented on this team are as follows:

1 civilian Ph.D.-M. D. neurophysiologist.
2 military medical officers, neurophysiologists.
2 military research biologists.
1 civilian electronics engineer.

(*d*) A team of six persons with specialized experience and capabilities for developing improved methods and techniques for the protection of personnel against hazardous exposures of high intensity noise and vibration. Specialties represented are as follows:

1 military research physiologist.
1 military research clinical psychologist
1 military research and development officer, biologist.
1 civilian audiologist.
1 military Ph D, speech and hearing specialist.
1 military medical officer, neurologist

(*e*) A team of four mathematicians and physicists with specialized knowledge and capabilities for applying mathematical methods and interpretations of the noise fields and shock waves generated by space vehicles under launch, flight, reentry, and recovery conditions Capabilities are also on hand for defining the effects of sound, shock, and vibrations in biological and other visco-elastic media.

Specialities represented are as follows:
1 civilian research mathematician.
2 military mathematicians.
1 military physicist.

2. Facilities

(*a*) *Bioacoustics research facility.*—A specialized acoustic research and development building with 15,911 square feet of floor area on two floors. Special wall and floor construction provides reduction of sound and vibration transmission. The facility is used for conducting studies pertaining to the action of sound and vibration on man; the generation of sound and vibration by Air Force equipment, the development, design, and test of noise and vibration control equipment, the development of protective procedures and other bioacoustics research programs. Low noise level rooms are available for calibrating bioacoustics and physical acoustics equipment such as microphones, level recorders, analyzers and audiometers. A special anechoic room provides a working space of the following dimensions: 22 feet by 22 feet by 22 feet. This room is used for research, development, and test experimentation where conditions simulating sound propagation is free space are required Such research projects include hearing studies on man and animals, the calibration or microphones, the study of the acoustical properties of jet sound sources and the calibration of special sound sources for generating very intense sound fields. To serve these functions the noise transmitted from the outside to the interior of the anechoic room is nondetectable by the human ear. Three reverberation rooms are used for testing sound control structures, for human and animal experiments requiring intense uniform sound fields and for evaluating the transmission loss of wall materials to be used in Air Force noise control structures.

Special laboratory rooms are available in the facility for research on human hearing, effects of noise on the ear and for electrophysiological and neurophysiological studies on the responses of man and animals to noise.

b. The vertical accelerator.—For use in determining the effects on humans or animals of buffeting, low frequency-high amplitude vibrations and impact The vertical accelerator will handle a maximum specimen weight of 400 pounds The specimen table has a total excursion of 20 feet peak to peak and operates up to 3 g from 1 cycle to 10 cycles per second. In addition it has an auxiliary vibrating motion which is driven off of the hydraulic system and operates at one-fourth inch peak to peak from 10 to 20 cycles per second. The machine was designed to simulate buffering, vibration, and impact encountered in operational situations in the Air Force.

(*c*) *Vibration table.*—A mechanical shake table for studying the physical, physiological, and psychological effects of vibration on humans. The table can be vibrated in three directions with variable amplitude in each direction. Frequency range is 10 to 50 cycles per second. Maximum specimen weight is 500 pounds. Maximum acceleration obtainable is 10 g.

3. Dollar value

The annual dollar value of the research effort of the Bioacoustics Branch is $5,000,000.

4. Suggested projects

(*a*) *Studies relating to vibrations, transient acceleration, and impact encountered in space vehicles.*—The objective will be to (1) acquire quantitative measurement of vibration, transient acceleration and impact encountered by occupants in launch, power flight, and atmospheric reentry of space vehicles; and (2) measure the physiological response of experimental animals subjected to these environments. Vibratory and accelerative patterns encountered will be simulated for study in the laboratory. Physiological measurements under actual flight conditions will be made for those environments which cannot be simulated in the laboratory.

(*b*) *Destructive noise and vibration environments.*—The technical objective will be to define the dynamic characteristics (vibration, noise, aeroelastic instability, and dynamic loads) in rocket-propelled vehicles This will reveal the important problem areas with respect to structure dynamics and accessory environment thus providing needed guidance in envolving a scientifically valid vibration and sound technology. Such basic data are essential in setting up design and labroatory simulation requirements and in advancing space technology toward the objective "Man in Space."

25973—58——78

ENGINEERING PSYCHOLOGY BRANCH

1. Number of personnel identified by technical specialty and component.

	Assigned		Vacant [1]	
	Civilian	Military	Civilian	Military
Research psychologist	25	12	20	3
Electronics engineer			2	
Engineering aide			1	
Mathematician	1		1	
Physicist			1	
Guided missile officer		1		

[1] These vacancies are a portion of those allocated to WADC as a result of the recent reorganization of the personnel and training research program in the Air Force. It is expected that they will be filled by September 1, 1958

Approximately 20 additional slots will become available when the present slots are filled.

2. Facilities including research capability, and use to which these facilities may be put.

(a) *C–131B aircraft.*—Completely instrumented for studying the performance and physiological reactions of aircrew members in flight. Also can be used to study brief periods of weightlessness as they effect the unrestrained man.

(b) *C–11B jet simulator.*—Completely instrumented for studying pilot performance as a function of a wide range of variables. Combines the reality of a flight situation with the control of the laboratory.

(c) *Air-bearing platform.*—Useful in studying man's ability to control body rotation in the vertical dimensions under conditions where he has little frictional contact with his environment. Such research is relevant to the problems of personal locomotion in space.

(d) *Gimbled device (3–D).*—Similar to device described above except that it allows "frictionless" movement in the three rotational dimensions. Useful in studying man's ability to control his body position and rotation in space.

(e) *Four-poster*—This device is useful in obtaining objective, quantitative indices of the mobility restrictions imposed by space suits and other protective garments. Such data are useful in evaluating protective garments and in designing work spaces for crew members wearing such garments.

(f) *Analogue commuters and function generators.*—This equipment is useful in simulating control display systems in real time and in studying human performance as a part of such systems.

(g) *Generalized laboratory space and equipment.*—The branch has a large amount of generalized laboratory equipment useful in studying all aspects of human performance as a part of a man-machine system Approximately 4000 sq. ft. of air conditioned laboratory space is also available.

3. Dollar value of your research effort (contract):

Fiscal year 1958	$789,000
Fiscal year 1959	[1] 1,084,000
Fiscal year 1960	[1] 2,073,000

[1] Ceiling.

4. Suggestions as to research projects which might lend themselves to civilian investigation.

(a) Effects of radiation on human performance. This would, of course, have to be limited to radiation which can be produced on earth.

(b) Effects of extended periods of isolation, confinement and sensory deprivations on human performance.

(c) Effects of exposure to high intensity, low frequency magnetic fields on animal and human behavior.

(d) Effects of ionized breathing atmosphere on human performance.

This needs exploring.

Second, the usefulness of a man either for reconnaissance or attack purposes in an orbiting vehicle of modest altitudes, say, 150 miles.

Third, the feasibility of putting a man on a so-called stationary orbiting vehicle at 22,000 miles distant from the earth, potentially a very useful observation platform for meteorological purposes and

relay station for electronic communication. Formidable problems of supply and transportation between earth and such a space platform would have to be solved.

When we have explored those three possibilities, then I think we will know to what extent man can be justifiably used from a military standpoint in space research and defense.

Mr. McDONOUGH. To what extent can we simulate these conditions without going up there?

Colonel STAPP. We lack one factor, a very important factor, which cannot be duplicated on earth. That is the effect of weightlessness.

In the case of the Dynasoar, or boost glide type vehicle, a man will be exposed to about 8 minutes of rather severe acceleration, then 30 or 40 minutes of varying degrees of subgravity, including 7 or 8 minutes of weightlessness, followed by a fairly prolonged low continuous decelleration in the reentry and recovery phases.

His ability to adjust to these numerous and frequent changes would have to be evaluated before we could determine just how much better a man would be than a black box in controlling the operation of such a weapon.

Mr. McDONOUGH. In other words, it is impossible to simulate the environment on earth inside of the cabin through all of those phases.

Colonel STAPP. We can simulate everything as long as it is one gravity or higher. If it is subgravity, we can only simulate that for periods of one minute or less in jet aircraft going through a parabolic trajectory, or shallow outside loop flight, where the force of gravity is offset by centrifugal force.

Mr. McDONOUGH. Now will you review the problems in the second one?

Colonel STAPP. The second one is prolonged weightlessness which cannot be simulated on earth. If you are going to keep a man up in orbit for twelve 1½-hour revolutions, that will be 18 hours of exposure to weightlessness. The only way we can find out how a man reacts to 18 hours of weightlessness is to put him in orbit. There is no way we can do it in any simulator at ground level.

And in regard to the third military application, I use the word "feasibility."

We have an extremely well-worked-out plan for getting man in space; it is the joint effort of all the laboratories of Wright Field.

This plan is classified, and it will be available for closed consideration by this committee if you so desire.

The CHAIRMAN. Have you completed your statement, Colonel?

Colonel STAPP. There is just one more point that I would like to cover. In relation to the value of a civilian agency as compared to the military agency in carrying out research with man.

In previous testimony, it was brought out that the boundaries between military and civilian approaches to space research began somewhere on the other side of the moon. I daresay that a military vehicle could get beyond the moon without being challenged.

However a vehicle with military insignia, inadvertently coming down on the wrong part of the earth might bring about numerous problems as compared to a well designated, well advertised purely civilian vehicle.

I would think that a civilian agency would have a great deal more freedom of research in terms of where the vehicle could come down

without misinterpretations leading to retaliation or exorbitant demands for reparations or other embarrassments.

That is all.

The CHAIRMAN. Mr. Metcalf, do you have any questions of either one of these gentlemen?

Mr. METCALF. Thank you, Mr. Chairman.

I would like to ask two questions. First, as I understand it, Dr. Strughold, the point at which you go from let us say terrestrial medicine to space medicine is, you say, 120 miles.

Dr. STRUGHOLD. Yes, sir. I think in order to better understand this whole field and the problems involved, we need a kind of "geography of space", a "spatiography" even in an environment which is distinguished by emptiness.

Now, first, we find within our atmosphere some environmental ecological conditions which are practically the same as those encountered in space. These space equivalent conditions begin at about 10 miles. From here on we enter space step by step and encounter total space equivalence at about 120 miles. This is the mechanical surface of the atmosphere, which means that in this altitude air resistance to any vehicle terminates. Those satellites which slightly touch the atmosphere during perigee and then go out into space again are very valuable for the exact determination of the range of this mechanical border between earth and space.

Now, above this mechanical border, around 120 to 140 miles, we enter extra-atmospheric space. But even in this area, space is different from open interplanetary space, because in certain respects the environmental, ecological conditions are still strongly influenced by the earth itself.

First of all, on one side we are protected against cosmic rays and meteorites by the earth's solid body.

Furthermore, the radiation environment in the vicinity of the earth is considerably modified by the earth's own and reflected radiation. The existence of a radiation belt formed by the geomagnetic field recently discovered through Explorer I by Dr. Van Allen also belongs in this environmental complex.

All this means that the space in the vicinity of the earth is ecologically different from open interplanetary space. But the influence of the earth gradually diminishes and at about 8,000 miles is no longer distinctly recognizable.

We may call the space in the vicinity of the earth up to about two earth radii "terrestrial space" (Krafft Ehricke), or we could call it "near space".

Above this region where the earth's influence upon the ecological qualities of space becomes of minor significance, we enter "extraterrestrial space", or "outer space".

There is another possibility for a topographical subdivision of space which can be based on the gravity of a celestial body. As is generally known from astronomy, the gravitational field of any celestial body extends theoretically ad infinitum. But in astronautics the area in which the gravitational field of a celestial body prevails is of special interest. And this is called the "sphere of gravitational influence" in the international literature. Actually, it is the sphere of predominant gravitational influence, and we may briefly call it "gravisphere". The earth's gravisphere reaches up to about 1 million miles. This is

the "gravitational territory" of the earth. It includes the arena of the satellites. It is the "satellite space" (Clyde Tombaugh). But the actual satellite space reaches only a little beyond the moon. And for the practical satellite space, i. e., for artificial satellites—we might assume an area up to about 22,000 miles, which altitude is the 24-hour orbit. The moon has its own gravisphere or its own gravitational territory. And Mars and Venus too.

A "geography of space," or "spatiography", based on the ecological and the gravitational situation seems to me useful for the problem of military and/or civilian control of space exploration. I believe that up to about 1 million miles—that means within the terrestrial gravisphere, the military authorities and the civilian authorities should cooperate and that the vast space beyond the earth's gravitational territory could be the exclusive realm of a civilian authority; i. e., beyond about 1 million miles where the gravitational predominance of the earth terminates. How far the "sphere of military interest" actually extends within the gravisphere is up to the Armed Forces to decide.

Mr. METCALF. However, there wouldn't be any conflict, would there, when we say that one of the objectives of this new Commission, NASA, is to develop and operate vehicles capable of carrying living organisms through space. That would mean living organisms through an area of 120 miles and beyond. It wouldn't include below 120 miles.

Dr. STRUGHOLD. For a joint cooperation it would include all the area from 12 miles to 120 miles. This is the partially space equivalent region of the atmosphere. For instance, the recent high altitude rocket flights in balloons and rocket-powered planes are space operations of an experimental space equivalent type. They were carried out—to a great extent—under the same conditions found in space, but still within the atmosphere. I would like to add at this point that space medical research must be continued at the same places within the Air Force and the Navy where they have been started, and are presently being carried on. A change in this respect would cause a considerable time delay, which we cannot afford.

Mr. METCALF. Colonel Stapp, you say that there are three biomedical research laboratories the Air Force is operating at the present time?

Colonel STAPP. Yes.

Mr. METCALF. Are those available for civilian research now?

Colonel STAPP. They would be if they were authorized to go ahead on research problems for a civilian agency; yes, sir.

Mr. METCALF. What if somebody in the NACA, for example, set up some civilian research project, would these Air Force laboratories be available for those?

Colonel STAPP. On an informal basis on other problems.

I have worked with NACA. I am a member of a subcommittee on flight safety. We have done research in cooperation with NACA in that field. It was not done with any transfer of funds but just informally.

On the same basis, I have carried out space research with two agencies of the United States Navy. One, the research track at Naval Ordnance Research Station at China Lake, Calif., where we have been doing hypersonic wind blast biological experiments. The other, the Navy's large centrifuge at Johnsville. We work at laboratory level in complete harmony and with very little formality.

Mr. METCALF. Now, suppose the National Science Foundation, the National Academy of Science, had some civilian project to try to work out, do you think that they would be able to make use of these laboratories under the present legislation?

Colonel STAPP. There are administrative angles there that might become formal and a little beyond my knowledge on the subject. However at laboratory working level I am sure that we would be able to do any work anybody wanted.

Mr. METCALF. However, if this new Agency were created, there could be the fullest use of that laboratory and the coordination of that laboratory.

Colonel STAPP. Absolutely. In fact it would be to the best interest of our national capability if such an Agency made use of our laboratories rather than to set up competing laboratories that would derive their personnel from our staffs.

Mr. METCALF. Have you read the proposed bill that is before us?

Colonel STAPP. Yes, sir.

Mr. METCALF. Are you satisfied this bill gives enough authority to the Agency so that it could coordinate that work in these laboratories.

Colonel STAPP. I hope that is so; particularly after talking with some of the people in NACA.

Mr. METCALF. Thank you, Mr. Chairman.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. No questions.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. No questions.

The CHAIRMAN. Mr. McDonough.

Mr. McDONOUGH. Dr. Strughold on page 2 of your statement you say for several years the Russians have stood on their own feet and the progress made by them is evidenced by animal experiments in rockets and by Sputnik 2.

The only animal experiment that I know of is Sputnik 2. Do you know of other experiments in animal experiments that we have conducted in satellites?

Dr. STRUGHOLD. Yes. About 2 years ago they sent dogs up to an altitude of about 100 kilometers. And they were brought back to the earth by parachute.

Mr. McDONOUGH. Did they find any more out from that than we found out from Major Simmons?

Dr. STRUGHOLD. No. The results of these experiments were the same as in similar rocket experiments carried out with monkeys by Dr. J. Henry in 1952 in Holloman Air Force Base.

Mr. McDONOUGH. I think you have made quite a contribution to the committee. I appreciate your appearance here.

No further questions.

The CHAIRMAN. Mr Keating.

Mr. KEATING. Colonel, you handled the experiment of Major Simmons, did you not? You supervised that?

Colonel STAPP. Yes, sir; I was in charge of it. It was my idea in the first place. I took complete responsibility for the experiment.

Mr. KEATING. Is he all right now? He had no ill effects whatever?

Colonel STAPP. None except the ill effects of numerous banquets and luncheons.

Mr. KEATING. None as a result of the experiment?

Colonel STAPP. No, sir.

Mr. KEATING. Why can't we simulate weightlessness for longer than 5 or 6 minutes in an experiment? In other words, if we can do that that long, why can't we do it longer?

Colonel STAPP. Well, the jet aircraft has to climb to 20,000 or 25,000 feet altitude and get up to speeds exceeding 400 knots. And then go into this shallow outside loop and maintain it to a point where pullout must be accomplished in order to keep from getting too low and endangering aircraft with hitting the earth. This limits duration to less than 1 minute.

Mr. KEATING. That is the way you simulate weightlessness.

Colonel STAPP. That is right. Such an experiment is vitiated by about 3 times gravity of force acting on the aircraft during entry into this configuration; and then a pullout of 3 or 4 times gravity at the end of the brief exposure, so that we cannot discriminate between transition effects and maintained zero gravity effects.

Mr. KEATING. Do you plan any new experiments, similar to the one which Major Simmons went through, in the near future.

Colonel STAPP. We plan a similar flight in June.

Mr. KEATING. That is all.

The CHAIRMAN. Mr. Ford?

Mr. FORD. Dr. Strughold, why is the introduction of the metric system so essential?

Dr. STRUGHOLD. For several reasons: First, the metric system or the gram-centimeter-liter system is so simple and clear. It therefore has no deterrent effect upon students to enter the field of natural sciences. It also makes it easy to understand immediately the international literature, and it is therefore not so time consuming as the English system. This system of the old colonial times cannot survive this coming space age. The metric system based on 1, 10, 100, 1,000, and so on, should be generally introduced now, just the same as it is in the monetary system.

The introduction of the metric system in the Soviet Union is to a great extent responsible for the success of the Russians in rocketry. They introduced it in October 1917.

Before and during the last war, the Russians had no experience in the construction and operation of large rockets of the V-2 type. They had experience with small rockets, and they also had a good knowledge in the fundamentals of rocket science.

However, after the war they obtained the blueprints of the V-2 which, of course, were based on the metric system. And immediately in 1946 they began to build V-2's. They could do it without time delay, because they did not need to translate the metric system into the old czaristic system of measures.

Mr. FORD. What system did they use prior to October 1917?

Dr. STRUGHOLD. They used units of measures, such as the arshin, pud, and werst, which are similar to those of the English system. After the October revolution, they switched over to the metric system in science and technology with regard to tools, work machinery, and so forth. Because of this, they were able to build V-2's themselves, and since 1947 they have built several thousands of them.

Consequently, they had a whole arsenal ready for training purposes, and I am of the opinion that this is one of the reasons that they have met with such success in this field.

I would like to add here also that if you attend any meetings on astronomy, astronautics, rocket, or satellite panels here in the United States, you will observe that the metric system has recently come into use more and more just the same as in nuclear physics. But in certain areas, such as engineering, this is not yet so.

Mr. KEATING. How did you get into this space medicine field?

Dr. STRUGHOLD. I started with aviation medicine in 1927. And to get in space medicine is nothing else but a matter of logic. There is nothing particular about it.

Mr KEATING Thank you very much.

Mr. CHAIRMAN. Doctor, I was interested on page 4 as to how research can be improved, and you put your No. 1 by minimization of redtape. Will you clarify that, please? We understand it, but we want it in connection with you gentlemen.

Dr. STRUGHOLD. I have no particular things in mind. But I would like to emphasize that there are too many committees. I mean in the engineering and scientific sector. Sometimes too many completely incompetent people have to give their approval. As an example, I would like to refer to a certain project of Dr. Walter Dornberger which, from a medical point of view, seems sound to me. Dr. Dornberger has been to Randolph Air Force Base at least three times since 1954 to discuss all the medical problems involved. And I had the opinion 3 years ago that he would have his vehicle in the sky in about 1957. But this is not the case, and I think that this is due to too many committees to which he had to submit the project for approval.

Mr. CHAIRMAN. You have given excellent testimony, both of you gentlemen, on the space medicine, the logical extension of aviation medicine. Is there any relationship? Could there be any relationship between biological and chemical warfare in space medicine?

Colonel STAPP. Very remote. Because safe use of such agents in terms of difficulty of getting them exactly where you want them would demand that you use a vehicle close enough to the earth to assure accurate placement of the chemical or the biological agents.

In other words, it takes airplanes or rockets to get the biological or chemical agents where you want them.

The CHAIRMAN. We read a lot about ballistic missiles, and so forth. But I understand that the potentialities of chemical and bilogical warfare are very far reaching. I am not talking now in connection with outer space. But I am talking about the situation that confronts us. Isn't that so?

Colonel STAPP. Well, I was a little confused at first because I was under the impression that you were thinking of using a space vehicle to carry biological or chemical warfare agents. A ground-to-ground or air-to-ground rocket or even a ballistic missile might be an effective vehicle for carring such agents to a target.

The CHAIRMAN. If, in other words, any potential enemy of ours or actual enemy should get far ahead of us in the field of biological or chemical warfare, it could be disastrous?

Colonel STAPP. Yes, sir. Likewise, psychological warfare.

The CHAIRMAN. Yes, I will include that also. And psychological, as you have used it, you mean as generally understood; isn't that right?

Colonel STAPP. Yes, sir.

The CHAIRMAN. Mr. Feldman.

Mr. FELDMAN. Doctor Stapp, would you be in favor of a provision—rather I should frame this in the affirmative—would you be in favor of a provision in the bill which would require the agency to use available facilities whenever they are in existence?

Colonel STAPP. Yes, sir. Because that would be the best way to conserve the effectiveness of these Air Force laboratory facilities.

Mr. FELDMAN. I believe that as between the military you have such a working arrangement in existence at the present time?

Colonel STAPP. We do; yes, sir.

Mr. FELDMAN. Is it possible that space stations——

The CHAIRMAN. Pardon me. In other words, you can easily make arrangements where, in connection with your laboratories and facilities, the military exigencies or considerations would not be ignored and the military be in control but make arrangements with the Space Agency or any other Agency where they could make use of your facilities under some kind of coordinated plan or cooperative idea.

Colonel STAPP. Yes, sir. Because the space research would be the same. Only the applications would differ.

The CHAIRMAN. And the interchange of information is valuable too.

Colonel STAPP. Yes, sir. And the same vehicle would carry experiments that would have different interpretations, or carry different experiments, civilian and military.

The CHAIRMAN. Your answers to these questions are very important because they become a part of a record which sort of shows the intent of Congress to a great extent. And these questions are not asked idly, because we realize the importance of establishing as broadly as possible the record. So that has a lot of governing influence after a law is passed.

What would be the approximate value of the facilities that you are connected with?

Colonel STAPP. We have 422 trained people working at the Aero Medical Laboratory at Wright Field. And I would estimate that two-thirds of them are doing work which has either direct or indirect application to space.

There are some 10 additional laboratories at Wright Field that would give use close support. For example, the equipment laboratory prepares, and does research on all parachutes that we would use in any recovery phase of a space experiment.

The plan which Wright Field has prepared, which I will try to obtain for the closed consideration of the committee, illustrates beautifully how these laboratories work together. The amount of resources in terms of equipment, dollar value of man-hours, and of the facilities brought to bear on the problem, depends on the size of the problem.

The CHAIRMAN. Mr. Feldman.

Mr. FELDMAN. Colonel Stapp, you spoke of a report that is being prepared. How soon will that report be ready, do you know?

Colonel STAPP. That should be ready within the next 10 days.

The CHAIRMAN. By the way, you gentlemen both will have the opportunity of editing your testimony and enlarging and more fully expressing your views upon reflection. And without objection the report will be made a part of the record.

Colonel STAPP. Thank you.

Mr. FELDMAN. Dr. Strughold, at the opening of these hearings Dr. von Braun described the project he was interested in which would send a man up in a Redstone 150 miles and give the man about 6 minutes of weightlessness. I believe 30 to 40 seconds is all that is possible by existing means. Would you characterize the von Braun plan as a circus stunt or useful from the space medical point of view?

Dr. STRUGHOLD. From the space medical point of view I would say if we consider such an experiment as a preliminary phase for the preparation of a more advanced operation, let's say into the neighborhood of the moon, it is a valuable experiment.

First of all, a man in such a vehicle would be familarized with the accelerations during the active period—this means during the launching. Second, he would have about 6 minutes of weightlessness, which is at least 7 times the total circulation time of our blood. Third, we would get some more information about the deceleration effects during reentry.

Mr. KEATING. May I interrupt there?

Mr. FELDMAN. Certainly.

Mr. KEATING. Is the circulation time of the blood of a chimpanzee about the same time of a human?

Dr. STRUGHOLD. It is a little shorter. The total circulation time of the human body is 55 seconds, or equivalent to 65 heartbeats.

Mr. KEATING. And the chimpanzee would be a little bit less than that?

Dr. STRUGHOLD. Yes, sir.

Mr. KEATING. And an animal like a mouse is much less?

Dr. STRUGHOLD. Yes, sir.

Mr. FELDMAN. Colonel Stapp, what is the maximum number of g's of gravity acceleration that you have experienced in rocket sled rides?

Colonel STAPP. 46.2 g's during a total exposure of one quarter of a second.

Mr. FELDMAN. What does that mean?

Colonel STAPP. It means applying 8,000 pounds of force for 80 milliseconds, during a total exposure to 250 milliseconds. That is 4 tons of mechanical force against the body.

Mr. FELDMAN. I was thinking of some standard measurement we could have by which we could compare this kind of force with the normal force, for example.

Colonel STAPP. If you went from 60 miles an hour to a stop in 3 feet, you would be exposed to the 8,000 pounds of force, but perhaps not for the same duration.

Mr. FELDMAN. In other words, it is a question of impact, is it?

Colonel STAPP. Impact force, yes. And that is applicable mainly to accidental forces.

Mr. FELDMAN. How would that be of value in connection with space flight?

Colonel STAPP. It at least proves that a man could survive some accidental very high exposure to force that might occur in a space missile flight.

However, of a little greater importance are experiments we have done on the centrifuge at Wright Field where we have simulated the

three stages of the rocket in terms of the magnitude and duration of force of gravity applied to the acceleration of the rocket. We find that a man can operate a guidance device for as long as 3 minutes while subjected to 8 times the force of gravity, applied transversely, or going from front to back of the body; and that with 12 times gravity an exposure lasting more than a minute can produce a blackout. Space accelerations have to be kept below 8 times gravity as a maximum, although as high as 10 times gravity could be allowed briefly.

On reentry it might be necessary to trade off a long exposure to a fairly low gravitational force to avoid excessive heating due to air friction. In other words, accomplish reentry slowdown by a prolonged deceleration in the outer atmosphere rather than by plunging steeply into resistant atmosphere and overheating.

We, therefore, have done centrifuge experiments where a man was exposed to 3 times gravity across the body for 1 hour. We found that 4 times gravity could be tolerated for about 20 minutes before it became too laborious as far as breathing is concerned.

Mr. KEATING. You personally participated in these sled experiments, did you not?

Colonel STAPP. That is right. I have had 29 sled rides.

Mr. KEATING. How fast did you go?

Colonel STAPP. The fastest I have gone is 632 miles an hour. That is not as important as the fact that I stopped in 1.4 seconds.

Mr. KEATING. You stopped in what?

Colonel STAPP. 1.4 seconds.

Mr. KEATING. Did you have any physical ill effects from that?

Colonel STAPP. I was put in the hospital for observation for five days at the end of which they turned me out on flying status. Therefore, there were no serious effects.

Mr. KEATING. Could you see all right after that?

Colonel STAPP. I had a temporary disturbance of vision after the exposure to this sudden stop, for a period of about eight minutes. All I could see was a red haze. But when I was put on a stretcher, the blood drained away from my eyes and I was able to see again.

Mr. KEATING. You volunteered for that experiment, didn't you?

Colonel STAPP. Yes, sir. And I would be prepared to do some more.

Mr. KEATING. I want to commend you for your courage. I think it is remarkable.

Colonel STAPP. Thank you, sir.

The CHAIRMAN. Any further questions?

(No response)

The CHAIRMAN. Well, Doctor Strughold and Colonel Stapp, we appreciate very much your appearings before us this afternoon.

Your testimony is very valuable because it is another part in making a well-rounded record for Members of the House and those discerning minds in the future who will be interested in it.

We appreciate your appearing before us, both of you gentlemen.

And as chairman, for myself and the other members of the committee I express my thanks to both of you, to Doctor Strughold and to you, Colonel Stapp.

Thank you very much.

(Additional material submitted by Dr. Strughold follows:)

Medical Problems Involved in Orbital Space Flight [1]

Hubertus Strughold [2]

School of Aviation Medicine, USAF, Randolph Air Force Base, Texas

After analyzing the various kinds of space operations that might be expected in the near or remote future (space equivalent flight, circumplanetary space flight, and interplanetary space travel), the second phase—circumplanetary space flight or orbital space flight—is chosen as a platform for the discussion of some of the most important medical problems involved in space operations. First, the state of weightlessness is discussed with regard to its effect upon the general well-being of the occupants of a satellite vehicle and in regard to its sensomotor effects. In connection herewith, the optical situation is considered with regard to the properties of the environment and the visual appearance of the light sources. Furthermore, physiological day-night cycling is discussed in an environment where there is no natural day and night. And finally some problems involved in human engineering of the space cabin concerning pressurization, supply of oxygen and removal of carbon dioxide, photosynthetic gas exchange and the event of sudden decompression of the cabin are discussed. Some of these problems are presently under study in an experimental space cabin simulator.

INTRODUCTION

For about seven years space medicine—a branch of aviation medicine—has been studying the human factors involved in flights into the upper atmosphere and beyond, into space. There are various phases of this kind of flight depending upon the physical and physiological characteristics of the environment, the speed of the vehicle, and upon the destination of the flight.

The first phase of space operations that we can expect in the immediate future will be the long distance flights at supersonic and hypersonic speeds through the space equivalent regions of the higher and upper atmosphere. These flights will be the logical development of the present-day long distance atmospheric flights on a global scale and can justly be called global or long distance space equivalent flights. With regard to motion dynamics, part of the time the vehicle exhibits airplane status and part of the time projectile status. We are now at the threshold of this first phase of space flight, namely, global space equivalent flight (10, 27).[3]

The second phase in the development of human space flight will have been achieved as soon as the orbital velocity of about 17,500 mph has been reached. This speed, which enables a vehicle to circle for a longer period of time or even permanently around the earth in an orbit, gives the vehicle satellite status. This is circumplanetary space flight or, more specifically, circumterrestrial space flight (4).

As soon as the escape velocity of 25,000 mph has been reached, the vehicle will have attained spaceship status, this will be the final phase of space flight and can truly be called interplanetary space travel (34).

It is my purpose in this paper to discuss the medical problems involved in the second phase of space operations, namely, that of circumplanetary space flight or satellite flight This is full-fledged space flight in its simplest form: full-fledged, because all of the strange environmental and motion conditions associated with space flight are encountered; in its simplest form, because the vehicle's movement is uniform with regard to speed and trajectory. Circumplanetary space flight, therefore, is an especially suitable example for discussion of the fundamental medical problems confronted in space flight. As for its technical side, see (4, 9, 11, 21, 24, 25, 26, 31, and 34).

The first step in the direction of this phase of space flight is the instrumented unmanned satellite, such as the one to be launched in 1957 (18); but we shall take a step further and assume, for the purpose of our discussion, an instrumented manned satellite. We shall not, however, discuss how this vehicle arrives at its

[1] Presented at the ARS 25th Anniversary Annual Meeting, Chicago, Ill., Nov. 14-18, 1955
[2] Chief, Department of Space Medicine. Mem ARS.
[3] Numbers in parentheses indicate References at end of paper.

orbit and the medical (acceleration) problems involved—which are not insurmountable—but rather we shall presume to be at the stage where the vehicle has already reached a certain orbit and has attained satellite status. But, I should like to add at this point, this paper in no way directly relates to the scientific satellite program which is presently under way.

The speed required to attain satellite status is about 18,000 mph near sea level. The denser regions of the atmosphere would prohibit this speed because of air resistance and friction heat. At about 120 miles or 200 km, however, the air is without noticeable effect in both respects (5). This aerodynamic and aerothermodynamic border of the atmosphere can therefore be designated by the more general term, flight effective limit or final functional limit of the atmosphere. The actual material border of the atmosphere, however, reaches into the area of 600 miles or 1,000 km from where we enter, through a 600-mile-wide spray zone, into interplanetary space. But it must be emphasized that even above the final functional border the atmospheric environment is space equivalent in practically every respect. It is here that the laws of aerodynamics lose their meaning and those of astrodynamics (Romick) become fully effective, rather than at the material limit of the atmosphere.

Above 120 miles, therefore, the nearest satellite orbit is conceivable. The orbital speed required at this level is, roughly, 17,500 mph and the period of revolution is about 88 min. Naturally, with increasing altitude, the orbital velocity decreases and the period of revolution increases

For our medical discussion, let us assume the 2-hr orbit slightly above 1,000 miles, as chosen by W. von Braun for his space platform. At this altitude we are in the exosphere, far beyond the final functional limit and also beyond the material limit of the atmosphere. The particle density is about 10 per cm^3. In the 2-hr orbit the orbital velocity is about 15,800 mph.

WEIGHTLESSNESS

Characteristic of orbital flight is the fact that the gravitational pull of the earth and the centrifugal forces caused by the vehicle's inertia are balanced, which means that the vehicle and its occupants are in the state of weightlessness or zero gravity. This is the first of the medical problems that I would like to discuss. There are two sides to this problem: (*a*) the general medical aspect regarding the well-being of the occupants, and (*b*) the sensory physiological aspect concerning perception of position of the body in space and senso-motor control of the movement of the body and its parts.

So far, experiments on man—to study the effect of zero gravity (16)—have been carried out only up to 30 sec. in parabolic flight maneuvers in jet planes. The experiments of E. R. Ballinger (2) in Wright Field Aero-Medical Laboratory in 1952, those of Harold von Beckh in Buenos Aires (3) in 1953, and most recently those of S. J. Gerathewohl in Randolph Field, Tex., do not as a rule indicate a general disturbance in the automatic nervous system which controls respiration and circulation. J. P. Henry et al. (17) in their recordings on monkeys in a V-2 and an Aerobee during a 3-min. period of zero gravity, found no evidence of a significant disturbance of the cardiovascular or respiratory system. So far, we have no proof that there would be any difference during a longer period of time, such as would be found in a satellite. A possible shift in blood pressure, due to the absence of hydrostatic pressure in the blood vessels, might be easily regulated by the presso-regulators of the arterial system. The whole problem boils down to the question of the possibility of adaptation to the state of zero gravity. Such adaptation seems to be a possibility At this point, I should like to add that a manned artificial satellite is the only means of bringing about a final solution of this entire problem, because it alone offers the possibility of experiencing the gravity-free state for periods of days, weeks, and months, not too far from the earth.

As to the second, or the sensory aspect of the gravity-free state, this can be said: we have several sense organs, or specific nerve endings, that serve as gravireceptors, such as the centrally located otolith organ and the receptors of the pressure sense distributed peripherally over the entire skin (about 20 per cm^2), specific nerve endings in the muscles, the so-called muscle spindles, and, finally, specific nerve endings in the connective tissue, the Pacinian corpuscles. They all, belong to the category of mechanoreceptors, these receptors have an exteroceptive function insofar as they react to external forces and inform us about the outer world. One such external force is the gravitational pull of the earth. They also have an enteroceptive or a proprioceptive function insofar as they inform us about the tension conditions in the skin, the muscles, and the connective tissue.

They play, therefore, an important role in the sensomotor control of the movements of the whole body as well as of its parts. In the case of the vestibular apparatus and the pressoreceptors of the skin, the exteroceptive function is more pronounced, in the other mechanoreceptors, the proprioceptive function is dominant.

In the gravity-free state the exteroceptive or the gravireceptive function of the mechano-receptors is eliminated, the proprioceptive function, however, is not. For this reason, a man making a high dive from a diving board is able to perform a variety of acrobatic jumps quite skillfully, although he is in a gravity-free state throughout the dive. In a gravity-free state the absent gravireceptive (exteroceptive) function of the mechanoreceptors is substituted by the exteroceptive sensory organ par excellence: the photoreceptors or, in other words, the eyes. When in the gravity-free state, as in a satellite, the eyes will be the only sense organ that informs the occupants of their position in space. This brings us to the problem of vision in space.

VISUAL PROBLEMS

Of what kind are the light sources that confront us in space? Direct sunlight and starlight are first, we are also confronted by indirect sunlight coming from the earth, reflected by the continents, the oceans, and especially by the clouds. Moreover, some of the indirect sunlight is scattered from the denser layers of the atmosphere back into space. Finally, we have indirect sunlight reflected from the moon's surface. But there is no skylight and this is the factor that makes the visual conditions so strange in the regions where satellites are conceivable. Skylight is sunlight scattered in all directions by the air molecules. Because the short wave part of the visible spectrum is especially affected, the scattering produces the diffuse blue daylight in the denser regions of the atmosphere, as it is observed from the earth's surface. Against this rather bright skylight, during the daytime the stars fade into invisibility. With increasing rarefication of the air molecules in higher altitudes, scattering of light diminishes gradually and ceases at about 80 to 100 miles (15). This is the optical functional border between atmosphere and space or the visual space equivalent level within the atmosphere. It is the dividing line between atmospheric optics and space optics. Beyond this level the sky is permanently dark. The extra-atmospheric sky luminance is only 10^{-5} mL as compared with that of 500 mL the average value in the lower atmosphere. But the sun is visible in its full brilliance against the dark sky, except of course when the satellite moves through the shadow of the earth. The stars are also visible all the time, and when its position allows, the moon can be seen in full brightness together with the sun. Because of the lack of skylight in space, the contrast between light and dark is a dominant feature. Everything that is exposed to sunlight appears in full brightness and vivid color, and everything else is in the darkness of shadow. The extra-atmospheric illumination is around 13,500 ft-c compared with 10,000 ft-c at the earth's surface. Light and shadow dominate the scenery, comparable to the light and shadow effects such as those produced on the stage for the magician. This strange photoscotic condition poses physiological problems in the field of contrast vision and retinal adaptation (7, 15). And the strange distribution of the light sources, sun, stars, and the indirect sunlight from the earth and moon, is of special interest from the standpoint of orientation in space (6).

At this point I should like to make a comparison with an environment that is, so to speak, the extreme opposite of that found in space, namely, the deep sea. But there are also some similarities, according to the well-known proverb, "les extremes se touchent."

W. Beebe observed in his "bathysphere" that the light intensity in the sea decreases rapidly with increasing depths. At a depth of 1600 ft., light is completely absent in the Atlantic Ocean. In these regions we find fish with luminous organs and telescopic cylindrical eyes. At depths of about 10,000 ft. there are fish with only vestigial eyes. These deep sea fish rely almost entirely on the mechano-sensory system of their skin to sense the environment. This represents an extreme contrast to the situation that will be experienced by man under space conditions. In the darkness of the deep sea, where the photo-receptors are out of function, the position and movement of the fish is controlled solely by the gravireceptors, in the darkness of deep space and under the gravitational conditions of orbital space flight where the gravi-receptive function of the mechano-receptors is eliminated, orientation of man depends entirely upon the photo-receptors or upon vision.

We do not know whether man can adjust to purely optical orientation in space. Fish can be trained for an optical orientation in their environment. Several years ago it was found by E. von Holst that when an aquarium in a dark room was covered with a black plate and the light penetrated through the glass bottom, some of the fish will swim upside down, and will look for fresh air at the bottom which is lighted and will swim to the dark surface of the water when they want to rest.

In orbital space flight, the sun, the stars, and the earth and moon are the optical footholds for the visual orientation in space. The observation of the sun, however, poses an important medical problem. The brilliant radiance of the sun in its original intensity, while not affected by atmospheric absorption and scattering, represents a hazard to the eyes. A much shorter time of exposure is sufficient to cause a retinal burn, such as that known to the ophthalmologist, as it occurs occasionally when someone observes a solar eclipse through an insufficiently smoked glass. The result of such a so-called "eclipse blindness" is a scotoma or a blind spot in the visual field. Outside of the atmosphere, the danger of such a retinal injury by direct solar light is much greater, and from an artificial satellite the sun should be observed only through glass with very high absorptive power.

In connection with the optical conditions found in the space equivalent regions of the atmosphere beyond 120 miles and in interplanetary space, I should like to touch upon a physiological problem that has never been discussed in space medical papers. It is the problem of maintenance of an adequate physiological day-night cycle for the occupants of a space vehicle.

PHYSIOLOGICAL DAY-NIGHT CYCLING

In orbital space flight, the concept of natural night loses its meaning and must be replaced by that which night really is, namely, the shadow of the earth.

The shadow or umbra of the earth tapers down in the form of a cone 859,000 miles or 1,385,000 km deep into interplanetary space. Travling through the greatest width of this sunless dark cone would take our assumed satellite about 50 min. During the remaining part of the revolution (about 70 min.) the vehicle is exposed to the sun and surrounded by darkness at the same time, as described earlier. Such are the optical conditions if the satellite orbit passes through the earth's shadow.

Many different orbital planes, however, are conceivable; in every case at a distance of about 1,000 miles an adequate ambient physical day-night cycle is absent because the day-night or, more precisely, the sunlight-shadow cycle is only 2 hr. Therefore, we must create and maintain an artificial day-night cycle within the satellite to meet the physiological requirements of the occupants. For, adequate diurnal cycling is of great importance to the health and efficiency of man. In fact we are physiologically so strongly adapted or so bound to a day-night cycle, manifested in rest or sleep and wakefulness or activity, that it must be regarded as a biological law. To ignore this law, after a week or so, would lead to a complete nervous breakdown (19, 33).

How can an adequate day-night cycle be achieved for the occupants of an artificial satellite? For them, the night must be induced in a special night compartment or by a device covering the eyes. The question is posed as to the time pattern of such an artificial day-night period.

In this regard, reference is made to the important basic experiments carried out in the Mammouth Cave in Kentucky, 1940, by N. Kleitmann, Professor of Physiology at the University of Chicago (19). Dr. Kleitmann spent two months in this cave with several co-workers, under artificially regulated day-night cycles of different lengths. The result of these experiments showed that man can adapt himself to a diurnal cycle only in the range from 18 to 28 hr. Within this range the temperature curve of the body follows the various cycles. When a cycle shorter than 18 hr or longer than 28 hrs was introduced, no adaptation was possible and the temperature curve returned to its normal cycle of 24 hr.

This gives us the clue for solving the problem of diurnal cycling in a manned satellite. If we choose a minimum day-night cycle of 18 hr, dividing it into 8 hr for sleep, 2 hr for recreation, and 8 hr for duty, that would be a reasonable solution. Or, if a 24-hr day-night cycle is selected, the best plan for a subdividion of this cycle would be 8 hr for sleep, 8 hr for rest and recreation, and 8 hr for duty. This presupposes that the crew will be large enough to be subdivided into three groups. In the case of an artificial 18- or 20-hr day-night cycle, a two-group crew would be sufficient for a manned satellite operation.

HUMAN ENGINEERING OF SPACE CABIN

We may assume that the metabolic rate of an occupant of an artificial satellite during his duty hours is about the same as that of an individual on earth during moderate work; the total metabolism during a 24-hr period, including sleep and recreation, would then be on the order of 2,500 cal for a 70-kg. man This brings us to the respiratory requirements for the satellite crew or, more generally speaking, to the climatization of the cabin (1, 13, 22, 7). The cabin in a satellite must, of course, be completely closed—a sealed cabin in which an adequate atmosphere is artificially created and controlled. It must be emphasized, however, that such a type of cabin is required even down to the atmospheric region of 70,000 to 80,000 ft.

One of the vital tasks in the climatization of the sealed cabin is the solution of the oxygen problem for respiration.

From the aforementioned metabolic rate of 2,500 cal per man per day, we can calculate the amount of oxygen required by 1 man per day. The thermal equivalent of 1l of oxygen is 4 85 cal under normal nutritional conditions. This means that the biological production of 1 cal requires 206 cm^3 of oxygen. Consequently, the total amount of oxygen consumed per man per 24 hr is roughly 500 l or 0.7 kg. This amounts to 58 kg of oxygen per man for 1,000 satellite revolutions that take place in 83 days in our assumed orbit at the 1,000-mile altitude, or 348 kg O_2 for a crew of 6. Replacement of the consumed oxygen from the storage tanks must be controlled in such a way that the oxygen pressure does not fall below 100 mm. Hg. This is about the minimum permissible limit for comfort and efficiency; it should not surpass the permissible maximum of about 350 mm. Hg because O_2 concentrations above this level are toxic (8). This shows that we can tolerate a rather wide variation in oxygen pressure (from 100 to 350 mm. Hg), which facilitates considerably the oxygen problem in space flight.

Whereas oxygen is consumed in the metabolic processes of the body cells, carbon dioxide is produced in the same process and exhaled. Under normal nutritional conditions, the ratio between exhaled carbon dioxide and consumed oxygen, the so-called respiratory quotient, is 0 85. In our example, one man produces 425 l of carbon dioxide or 0 837 kg. per day or 70 kg. per 1,000 satellite revolutions. This would be 420 kg. for a crew of 6. Carbon dioxide in concentrations above 3 vol. percent is toxic, the permissible limit for a longer period of time lies at about 1 vol. percent under standard barometric pressure and temperature conditions, or at about 8 mm Hg. The removal of the excess carbon dioxide in the sealed cabin vehicle, which can be achieved by certain chemicals or in a physical way is, therefore, just as vital as the maintenance of an adequate oxygen pressure.

Since the consumed oxygen appears again in bound form, namely, within the carbon dioxide of the expired air, it has been suggested to try to regain the oxygen from the carbon dioxide, in this way eliminating a toxic gas and at the same time facilitating the problem of oxygen supply.

A natural method accomplishing this is known to us in the process of photosynthesis, found in chlorophyl-bearing plants. Photosynthesis is the reverse process of respiration as a comparison of their reaction formulas shows

Respiration: $C_6H_{12}O_6 + O_2 \rightarrow 6CO_2 + 6H_2O + \text{Energy}$
Photosynthesis: $6CO_2 + 6H_2O + \text{Light Energy} \rightarrow C_6H_{12}O_2 + O_2$

In respiration or biological oxidation, oxygen is consumed and carbon dioxide and water are produced. This process requires several so-called respiratory enzymes In photosynthesis, oxygen is produced and carbon dioxide and water are consumed This process requires the presence of chlorophyl as an enzyme.

In special studies sponsored by the USAF School of Aviation Medicine, it has been found by J. Myers, head of the Department of Algal Physiology, University of Texas, Austin (23), that 2 3 kg. fresh weight of a certain alga—the alga chlorella pyrenoidosa—with regard to gas metabolism, under optimal conditions, is sufficient to support one man. This means that this mass of algae consumes as much carbon dioxide and produces as much oxygen per time unit as one man produces carbon dioxide and consumes oxygen during the same period of time. Both, therefore, could live together and support each other with regard to the respective respiratory and photosynthetic requirements in a symbioticlike relationship in a closed system for a considerable length of time.

Plants like the alga chlorella are especially suitable as photosynthetic gas exchangers. They are small round bodies about the size of red blood cells and are dispersed in a nutritional solution. These primitive plants are perfect photosynthetic machines, since they have no specific organs nor various functions like the higher plants. Their only function is to build up carbohydrates and to produce oxygen photosynthetically. Primitive plants of this type appeared on this planet 1½ billion years ago. And they might have been responsible for an early buildup of an initial stock of oxygen in the primitive atmosphere or proto-atmosphere of the natural satellite of the sun, namely, the earth. But the difficulties in the use of such photosynthetic gas exchangers lie in the volume and weight of the device, in the arrangement of and in the power requirement for illumination As for the latter, solar energy may be the answer. For flights of short duration, however, we certainly shall never resort to a biological gas exchanger. For flights over weeks and months it might be different. Perhaps some day we shall have a type of photosynthesis that can utilize infrared; or the efforts that have been made for a number of years in order to achieve artificial photosynthesis may one day be successful.

In the sealed cabin also, the water vapor given off—in amounts of from 50 to 80 gram per man per hour through respiration and perspiration under comfortable temperature conditions by the occupants—must be kept within the comfort limits that range between 80 and 50 percent relative humidity. And, finally, the barometric pressure should be kept at levels corresponding to that found near sea level and up to 9,000 ft In this respect, however, the physiologist could make concessions to the engineer, who for structural reasons would probably desire a lower pressure differential between the cabin's air and the surrounding near vacuum. From the physiological point of view, a minimal barometric pressure corresponding to an altitude of about 15,000 ft. would be acceptable.

The multitude of factors involved in the climatization of the sealed cabin requires a complex instrumentation for automatic control. The School of Aviation Medicine, USAF, Randolph Air Force Base, Tex., now has an experimental sealed chamber (fig. 1) in which we can study the changes of the atmospheric conditions caused by the presence of the occupants, and the means to control these factors. This space cabin simulator can also serve as an indoctrination chamber in handling the situation in case the automatic controls fail or the cabin develops a leak.

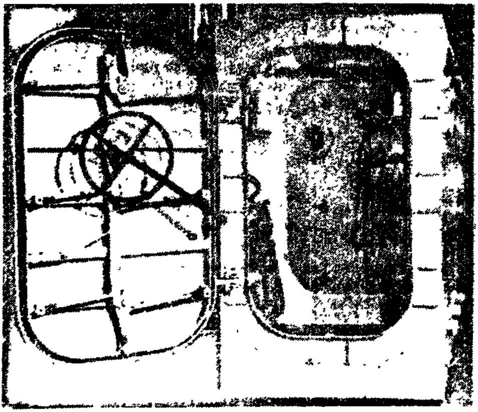

FIGURE 1 —The space cabin simulator of the School of Aviation Medicine, USAF, Randolph Air Force Base, Tex

25973—58——79

DECOMPRESSION EVENT OF THE SPACE CABIN

With this point we touch upon the Achilles' heel of the sealed cabin vehicle. One of the causes of a leak might be a collision with a meteor (20), a probability which is very remote; however, the occupants of a satellite vehicle must be prepared for such an event, even though meteor bumpers or screens—suggested by F. Whipple (35) and others—might offer effective protection

In the lower atmosphere, the time rate of decompression of the pressurized cabin is governed by four factors: the volume of the cabin, the size of the hole, the barometric pressure within the cabin, and the barometric pressure of the ambient atmosphere In a satellite vehicle, the last factor is practically zero, which means that under other equal conditions the decompression will be more violent. In any event, the crew must know that a drop in oxygen pressure to 100 mm. Hg will affect their efficiency, as mentioned earlier, and at an oxygen pressure of 60 mm Hg the situation will become critical and dangerous Before this critical level is reached, the source of the leak must be sealed; otherwise, the crew would face the whole physiological sequence of decreasing air pressure effects.

CONCLUSION

These are some of the medical problems encountered in obital space flight. I have not touched upon the radiation and temperature problem (12, 28, 29, 30) which has been discussed in the paper of David G Simons (30).

All of the space medical problems discussed so far are also encountered in transfer orbits to other celestial bodies, that is, in interplanetary space travel. Some of them will be faced also, more or less, during a certain portion of space equivalent flights, that is, in long distance flights at hypersonic speed through the space equivalent regions of the atmosphere, as previously defined But we find them, so to speak, in classical form in nearly circular orbital space flight.

I have chosen, therefore, this phase of space operations for this paper because it offers an ideal platform for the discussion of the problems of space medicine in general, and provides an up-to-date picture of some of the progress made in this fascinating branch of aviation medicine.

The Possibilities of an Inhabitable Extraterrestrial Environment Reachable From the Earth

By Hubertus Strughold,[1] M. D , Ph. D.

The problem of life on other worlds is a subject which captivates the imagination of mankind tremendously. Not until it was recognized by Copernicus in 1543 that the earth is not the center of the universe but rather only one of the members of the planetary family of the solar system, could such thoughts arise in the human mind. There are two technical events that have had a catalytic effect upon man's occupation with this question: The invention of the telescope some 350 years ago, which has brought the celestial bodies closer to us optically, and recently, the successful development of the rocket which possesses the potentialities of bringing us closer to them physically. Not only has the older question of the existence of indigenous life on other planets come anew into the focus of scientific and general public interest, but in addition, with the development of space operations, this question is posed: Are there planets in the solar system that offer an environment of such kind that an astronaut from the earth—the species homo sapiens terrestris—could land there and stay there for some time at least?

We get an answer to both of these points very quickly by projecting the specifications of the environment required, from the standpoint of human physiology and of general terrestrial biology, against the physical planetary data offered in the astronomical literature.

[1] Dr. Strughold is research adviser to the commandant, U. S. Air Force School of Aviation Medicine, Randolph Air Force Base, Tex.

Such a study can be called planetary ecology. For the science which particularly studies the possibility of indigenous life on the planets the terms "astrobiology" and "astrobotany" are in use. With regard to this latter problem this discussion will consider only the kind of life known to us, based on carbon as the structure atom and on oxygen as the energy liberation atom.

Table I shows a list of certain ecological factors indispensable for the existence of life such as: the presence of an atmosphere and a hydrosphere, or water in its liquid state, a biologically suitable temperature, carbon dioxide which is, in addition to water, the raw material for photosynthesis in green vegetation, and finally, oxygen, the key element in the biological energy liberation. The table further shows, by use of the marks + and − whether or not these ecological factors are found on the planets of our solar system. By screening the planets in this way, only Mars and Venus remain as bioplanets or conceivable bioplanets. And these planets are found in neighboring orbits near the sun only. The decisive factor responsible for this zonation of the planets with life-favoring conditions is the intensity of solar radiation which decreases with the inverse square of the distance from the sun. The difference in the radiation intensities to which the planets are exposed, and have been exposed since their protoplanetary stage, are therefore tremendous.

TABLE I.—*The planets and some of the ecological necessities for life*

Planets	Atmosphere	Hydrosphere	Biotemperature	Carbon dioxide	Oxygen
Mercury	−	−	−	−	−
Venus	+	(+)	+	+	(+)
Earth	+	+	+	+	+
Mars	+	(+)	+	+	(+)
Jupiter	+	(−)	−	−	−
Saturn	+	(−)	−	−	−
Uranus	+	(−)	−	−	−
Neptune	+	(−)	−	−	−
Pluto	+	(−)	−	−	−

+ present, (+) probably present in small amounts
− not present, (−) present in frozen state.

We get a dramatic picture of this by considering the size of the sun as seen at the distances of the various planetary orbits (Fig. 1). To an observer on Mercury the diameter of the solar disk would appear more than twice the size it does to us on earth As seen from Mars, the sun would have a considerably smaller apparent dimension than our moon. At the distance of Jupiter the sun's diameter is only one-fifth as large as seen from the earth, and at the distance of Pluto the sun would appear no larger than the evening star Venus appears to us on earth. This means that in the more remote portions of our planetary system, the role of the sun, as dominating source of light and heat energy, fades into that of a common star. If there were people on Pluto, these Plutonians would not even know the concept of a sun This consideration makes it quite clear why life-supporting planets are conceivable only in a certain zone within the planetary system.

More in detail, the visible section of the solar radiation spectrum presents a narrow zone of physiologically desirable planetary illumination, a kind of "euphotic belt" surrounded by dysphotic (hyperphotic and hypophotic) regions. With this we have added a new ecological factor not mentioned in Table I, namely, light. The infrared portion of solar radiation, as the main carrier of heat energy, is apparently effective in providing biologically acceptable temperatures on planets only in the range from Venus to Mars, which justifies our speaking of a "biotemperature belt" in the planetary system. The occurrence of water in this same zone represents a kind of "liquid water belt" in the planetary system (5).

Finally a zonal distribution is evidenced in the chemical composition of the planetary atmospheres. On the inner planets we find atmospheres containing oxygen, and such oxygen compound as carbon dioxide, while the atmospheres of the outer planets contain hydrogen and such hydrogen compounds as methane and ammonia. Originally about two and one-half billion years go, the atmospheres of all the planets were basically hydrogen and reduced atmospheres. This protoatmospheric composition dominated by hydrogen has been transformed in the course of many millions of years into one of oxygen and oxidized compounds by the effect of ultraviolet of solar radiation, but only on the planets relatively near the sun, namely, on Venus, Earth, and Mars. These planets, therefore, form a kind of atmospheric "oxygen belt" in the planetary system.

The atmospheres of the outer planets, moving beyond the effective reach of ultraviolet solar radiation, are still protoatmospheres preserved in a frozen state. They form a "hydrogen belt" of the primordial brand in the planetary system. But Jupiter, nearest to the sun in this outer belt, shows some indication of photochemical reactions in the upper atmospheric regions, manifested in green and reddish colorations, which have recently been interpreted by Rice (4) as caused by free radicals of methane and ammonia in a frozen state.

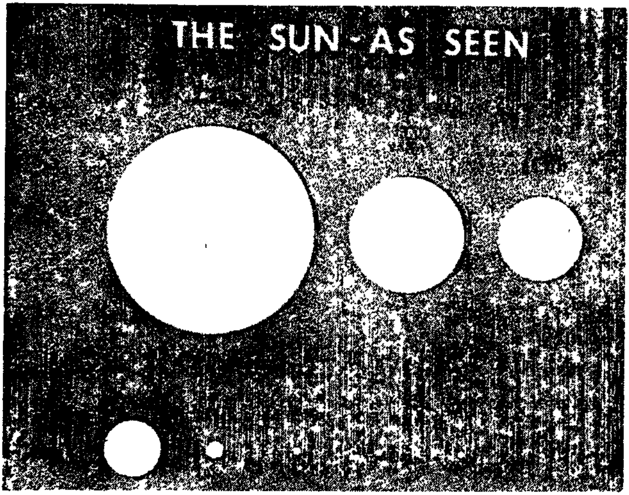

FIGURE 1.—Size of the sun as seen from the orbital distances of the various planets.

In summary, this general ecological consideration leads us to the assumption of specific life favoring ecological belts in the planetary system such as an euphotic belt, biotemperature belt, liquid water belt, and oxygen belt. Because all of these belts are found in about the same region, they are therefore parts of a "general life zone" which we might call "ecosphere" in the solar planetary system and which is confined to the orbital range from Venus to Mars (fig. 2). This is the zone on the planets in which the kind of life now predominant on earth is conceivable. On the planets in the hydrogen belt, micro-organisms such as hydrogen-, ammonia-, methane-, and iron-bacteria, are conceivable; these are the kind which probably populated the earth during its protoplanet stage some two billion years ago and which we still find today in the pores of the soil and other poorly aerated spaces. However, the low temperature on the outer, so to speak, permafrost planets excludes the possibility of life in the hydrogen belt. The sun's radiation in this region apparently has not been sufficiently effective to change the atmospheric environment on these planets into a biologic climate.

For all of these reasons, it would be ecologically impracticable to extend space operations beyond the well irradiated ecosphere to the outer planets with their hydrogen, methane and ammonia saturated atmospheres, and their arctic temperatures and surrounding midnight sun light conditions. But even the two ecologically acceptable planets, Venus and Mars, pose considerable medical problems. Because of lack of time, I will omit a discussion of Venus, whose surface features are wrapped in mystery by dense clouds of carbon dioxide, and shall concentrate upon Mars.

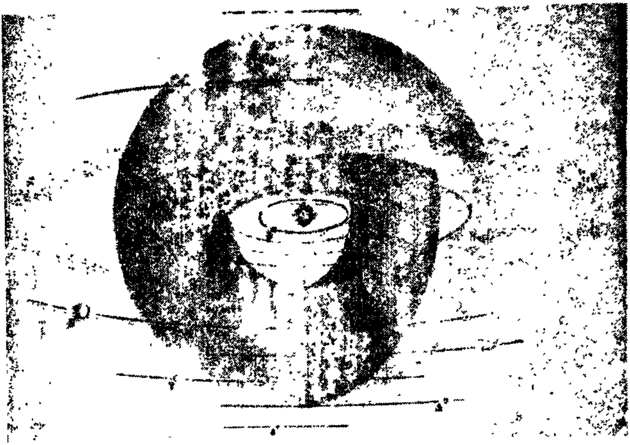

FIGURE 2.—Ecosphere or life zone of the planetary system comprising Venus, Earth, and Mars. Within this sphere lie the eupnotic biotemperature, liquid water and oxygen belts. All are essential to support life as we know it.

Of primary interest to the astronaut will be the question of the kind of atmospheric environment he would find there from the standpoint of human physiology, especially what protective measures he would have to take concerning respiration.

Atmospheric entry will pose fewer aerodynamic, aerothermodynamic and pertinent physiological difficulties than are encountered in the terrestrial atmosphere because of the lower air density. The most likely chemical composition according to de Vaucouleur (7) is as follows 98 5 percent nitrogen, 1.20 percent argon, 0.25 percent carbon dioxide, and oxygen < 0.12 volume percent The barometric pressure at ground level (there is, by the way, no sea level on Mars because of the absence of open bodies of water) is about 70 mm. Hg. or 95 millibar. This pressure corresponds to an altitude of 55,000 feet in our atmosphere (fig. 3). Barometrically, this altitude is the Mars equivalent level in our atmosphere. The oxygen pressure at ground level is probably lower than it is in our stratosphere.

Pilots flying at altitudes above 55,000 feet must wear pressure suits. The same would be required for an astronaut on Mars when he leaves the sealed compartment of his spaceship However, an air pressure of 70 mm. Hg. lies just within the critical border range in which a pressure suit, or simple oxygen equipment with pressure breathing, are a matter of dispute. Oxygen equipment with pressure breathing may be sufficient for shorter periods of time. Balke, (9) after spending six weeks at a height of 14,800 feet at Morococca, Peru, for acclimitization purposes, was able to withstand an altitude of 58,000 feet in a low pressure chamber for three minutes with pressure breathing only. A certain altitude adaptation of the astronaut can be expected if the air pressure in the sealed cabin is kept at a pressure of half an atmosphere during the trip. Be that as it may, a terrestrial explorer on Mars, wearing a pressure suit or pressure breathing device must always retreat, after an hour or hours depending on the efficiency of the equipment, into the more convenient sealed compartment of the ship, which should have its landing place in the lowlands because, with regard to the respiration equipment, every milimeter of Mercury of air pressure counts. Such a depressed area, for instance, is the Trivium Charontis, a dark greenish patch several thousand feet below the level of the surrounding desert.

In the event of a leak in the sealed compartment or in the pressure suit, the astronaut would encounter the same rapid decompression effects including anoxia and aeroembolism as the pilots do in our atmospheric region at about 50,000 to 55,000 feet. He would not, however, be endangered by "ebullism" a new term

(8) for the so-called "boiling" of body fluids. This effect becomes manifest on Mars at an altitude of 13,000 feet which corresponds to 63,000 feet in our atmosphere. These are the essential points which must be considered in insuring physiological air and oxygen pressure for an astronaut A factor which might facilitate the oxygen requirement and the mobility of the astronaut is the relatively low gravity on Mars, which is 38 percent of that on earth.

The temperature in summer during the day in the equatorial regions may reach 25° C. After sundown when the temperature drops very quickly to −45° C., the space cabin must provide adequate protection. Harmful effects from solar ultraviolet rays can be disregarded. Even if they were not sufficiently filtered out by the martian atmosphere, the skin of the astronaut is always protected from sunburn by the respiratory equipment or by the cabin. Health hazards from primary cosmic rays are probably not to be expected because of the atmosphere's absorbing power. The same certainly would be true concerning meteorites.

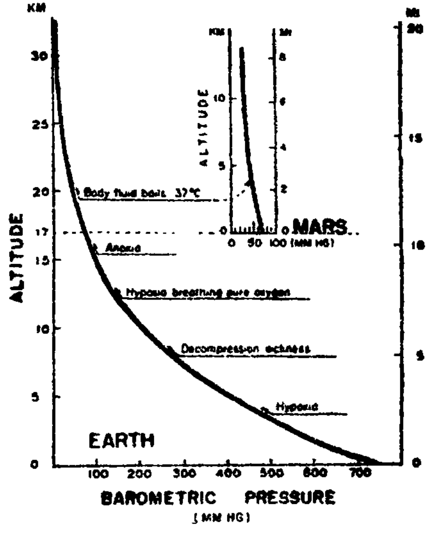

FIGURE 3.—Mars equivalent altitudes within the earth atmosphere. The altitudes and air pressures of the martian atmosphere are projected onto those of the earth. The curve shows points at which certain physiologic effects of decreasing air pressure are observed.

The intensity of daylight on Mars is lower than on earth but still in physiologically desirable limits. The color of the sky is probably whitish blue (2) due to scattering of light by the various hazy cloud layers. It might be that under this umbrella of whitish haze the sun would be invisible. Finally, an adaptation of the astronaut to a different day-night cycle is not necessary because the day-night cycle on Mars is only thirty-four minutes longer than that on earth. Such are the climatic environmental conditions that a terrestrial explorer probably will find on Mars from the standpoint of human physiology or, in other words, with regard to himself. A strange "second earth"!

Of particular interest for a terrestrial explorer on Mars will be the question: Does indigenous life exist on the planet itself? With this we touch upon the much discussed dark green areas in the equatorial regions which show seasonal color changes and therefore have been interpreted as vegetation. Will the

astronaut find that this is correct or will he find instead volcanic ash (3) or some hygroscopic inorganic material? (1) Recent spectroscopic studies seem to support the martian vegetation theory. The physical conditions are extremely severe with the exception of sufficient amounts of carbon dioxide and light. Such conditions, especially the extreme day-night temperature variations, according to terrestrial standards, could support only very hardy and cold resistant plants. We must, however, consider not only the climate as a whole but also the so-called microclimate near, on, and below the ground influenced by surface and subsurface features, snow coverings, hollows, and caves which usually moderate the extremes of the macroclimate Then there is the enormous capacity of life to adapt itself to abnormal climatic conditions. With regard to the specific environment on Mars we should consider the possibility of specific structures and properties of the plants for storing water, carbon dioxide and photo-synthetically produced oxygen. Such phenomena are well known in terrestrial biology Strong absorbing power of the plant surfaces are infrared and reflecting power for blue could be imagined as a means for temperature control and protection against ultraviolet, respectively, if the latter is necessary. The pronounced bluish tint of the green areas on Mars might offer a hint in this respect. Protection against frost might be possible if the martian plants were able to develop some kind of antifreeze such as glycerol. We know that even terrestrial animal cells can survive temperatures as low as −70° C when placed in glycerol solutions

The opinion has been expressed by Tikhoff (6) that a terrestrial climate which comes nearest to that on Mars with regard to temperature, radiation and humidity is that found on the Pamir plateau, a high mountain desert in Central West Asia, or that on the high plateau of Tibet. As previously mentioned, the air pressure conditions on Mars correspond to those in the lower region of our own stratosphere. So if we combine the microclimate of the Pamir plateau or Tibet with the macroclimatic air pressure milieu of the lower stratosphere, we have an approximation of the environment on Mars. It is more severe than on the Pamir plateau but friendlier to life than our stratosphere because of its higher temperature during the day.

Such is the picture than can presently be drawn of an extraterrestrial environment most probably reachable from the earth Whether or not this earthly conception corresponds to the martian reality, is a question that will probably remain open until a successful space operation to the green and red planet has been achieved. Until then, it will remain a common meeting place for discussion for astronomers, biologists, botanists and physiologists—in fact, for everybody.

From Aviation Medicine to Space Medicine [1]

By H. Strughold, M. D., Ph. D.

Department of Space Medicine, USAF School of Aviation Medicine, Randolph Field, Tex.

Space medicine appears with a special program of papers, for the first time, on the public platform of a scientific society—the Aero Medical Association. For this reason, it would seem that a few introductory remarks are appropriate. It is a privilege, and indeed a source of great pleasure, that this task has been delegated to me.

Space medicine, at first glance, undoubtedly appears to many people as a capricious or whimsical idea in aviation medicine. However, upon closer examination, it proves to be a very logical step in development. When we view it from a historical standpoint, starting with the predecessors of aviation medicine, we gain a better understanding of its scope and meaning.

Aviation medicine, throughout its 40 years of development, has benefited by the experiences gained in high-mountain physiology. As a science, high-mountain physiology is nearly 100 years old. Mountain sickness, however, was first described by José de Acosta in 1588. The first mention of this uncomfortable effect of thin air can be traced back to Greek literature, since it was Aristotle who observed that men could not live on the top of the 10,000-foot Mount Olympus in Thessaly without breathing through a wet sponge. High-mountain physiology, with all of its descendants, could very well claim as its birthplace, a holy mountain dedicated to Zeus or Jupiter.

Logically, twentieth century aviation medicine in its early years, was more or less concerned with the problems of cadet selection, reaction time, orientation, crashes, et cetera. The early issues of the Journal of Aviation Medicine tell this story. However, with the passing of time, interest in higher altitudes increased more and more. Experiments in low-pressure chambers and explosive decompression chambers opened the way into the tropopause and stratosphere. Extreme explosive decompression experiments (1), (6), (9), (12), (18), (19), and the medical evaluation of the balloon flight of the Explorer II (2) had already touched the area of space medicine. Aviation had attained a very high level in safety, efficiency, and comfort, as a result of the accomplishments of aviation medicine (1), (4), (9), (11), (21,). Only high-powered propeller planes and jet planes could still bring some progress in speed and high altitude flying

It was in this situation that the first rocket appeared in the sky and—within 5 years—exceeded all altitude records by 20 times. This was not only a signal for the engineering world, but a challenge to all sciences concerned with the human factor. This new revolutionary development becomes quite clear when we review the records of altitudes reached—during the past 150 years—by means of the balloon, airplane, and rocket. We note that the balloon and airplane, both depending upon air, are—in a way—confined to two-dimensional movement in the horizontal plane around the globe, whereas, only the rocket has really conquered the vertical—the third dimension—moving away from the earth. Considered from a global point of view, this shift in dimensions is the most conspicuous mark in the new development of flight. A new frontier has now been opened—the "vertical" frontier (5).

[1] Presented at the 23d annual meeting of the Aero Medical Association, Washington, D. C, March 17-19, 1952. Symposium on space medicine

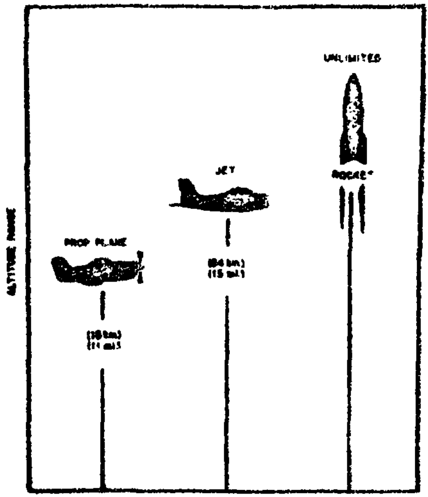

FIGURE 1. The vertical extent of the operational areas of propeller, jet, and rocket craft.

Figure 1 shows the vertical extent of the operational areas of propeller, jet, and rocket craft. The ultimate limit for propeller-driven planes is about 18 km. or 60,000 feet; for jet planes, about 24 km. or 80,000 feet; and rockets are limited only by their fuel capacity. With regard to speed, propeller-driven and jet planes have attained velocities in the neighborhood of the speed of sound. Rockets have practically no limitations of speed.

The limiting factor in height and speed, for conventional planes including jets, is the atmosphere. However, in the realm of the rocket, flying is no longer dependent upon air as a supporting medium. Thus, the factors with which we must deal in rocket flight are not properties of the atmosphere, but rather attributes of free space.

For this reason, a most logical step, and a daring one too, was the creation of a new branch of aviation medicine, space medicine In anticipation of this development, a special department, the Department of Space Medicine, was founded in 1949 by Major General Harry G. Armstrong, at that time Commandant of the USAF School of Aviation Medicine at Randolph Field, Texas. Problems concerning rocket flights were also being studied by the Aeromedical Laboratory at Wright Field about the same time.

The first open discussions in the field of space medicine were held at two earlier meetings, one called by General Armstrong in 1948 at the USAF School of Aviation Medicine, Randolph Field, Texas (3) and another organized by Dr. Andrew Ivy and Dr John D. Marbarger in 1950 at the University of Illinois in Chicago (20).

At the 1950 meeting of the Aero Medical Association in Chicago the creation of a space medicine branch of this organization was proposed, and at the 1951 meeting in Denver this branch was finally established with Col. Paul A. Campbell as its chairman. The foundation of this branch was a necessity in order that we could have a medical counterpart of the various rocket societies, space-flight societies, astronautical and interplanetary societies, which are exclusively technical in nature. It must be recognized that these societies, which exist in more than half a dozen countries, have shown great activity and success during recent years. The human factor in space flight, however, is as important as the technical factor.

Today the space medical branch of the Aero Medical Association offers a special program. Space medicine is no longer the diffuse area which it may have appeared to be a few years ago. The scope of its problems is now clearly defined. They have been clarified by the introduction of a new concept of the boundaries between the atmosphere and space, based on the function which the atmosphere has for man and craft (13, 23). This functional consideration demonstrates that at relatively low altitudes the various functions of the atmosphere cease, one after the other. Consequently, the various space factors take over. Such levels are properly called space equivalent altitudes (fig 2) In mentioning only a few of them, we meet space equivalent conditions with regard to—

Anoxia at 52,000 feet;
Body fluid boiling at 65,000 feet;
Heavy primaries of cosmic radiation at 120,000 feet; (22, 16)
Ultraviolet solar radiation at 135,000 feet; (17)
Optical appearance of the sky at 400,000 feet; (13) and
Meteorites at 500,000 feet. (34)

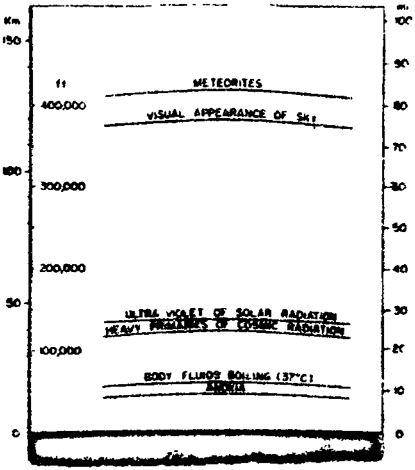

FIGURE 2.—Space equivalent and semiequivalent conditions within the earth's atmosphere. (For further details see text.)

It may be added that only the earth with its magnetic field, its radiation, and its bulk, modifies some of these conditions, making them different from those found at greater distance Since the bulk of earth affords protection from one-half of the cosmic radiation and meteorites, we may, in these particular cases, speak of semiequivalent conditions of space.

Space equivalent stages within the atmosphere must be considered in regard to the necessity for sealed cabins, and also with regard to pure radiation climate above a certain altitude. (7) Further, conditions characteristic of space originate in the motion of the craft, here, weightlessness is the most outstanding phenomenon. (8, 14, 15) This problem was first discussed by H. Haber in a seminar at the Aeromedical Center in Heidelberg in 1946 (10)

This approach, based on a functional concept of the atmosphere, clearly indicates that a differentiation must be made between two distinct regions of the physical atmosphere: The lower section is the realm of conventional flight where the properties of the atmosphere can be utilized, the upper section, beginning as low as 50,000 feet, where the functions of the atmosphere gradually become ineffective, has many properties in common with free space. It is indeed amazing

to observe that various environmental factors of space penetrate down to rather low altitudes. The usable portion of the atmosphere is a very thin shell. The so-called upper atmosphere of the physicist is equivalent to free space, for all practical purposes.

A symposium on the physics and medicine of the upper atmosphere was held in San Antonio, Tex., in November 1951. (25) This meeting, which was organized by Brig. Gen. Otis O. Benson, Jr., Commandant of the United States Air Force School of Aviation Medicine, and Dr Clayton S. White, director of research of the Lovelace Foundation, must be considered an important step toward clarifying the medical problems involved in flight in the highest strata of the atmosphere, where the various benefits derived from the presence of air fall short. The problems of flight in this area are different from those encountered in free space For this reason, the area was designated by a special term, namely, the aeropause (K. Buettner). (25) In a way, flight at present is in an amphibian stage, in a phase of transition between conventional aviation and future space flight

The technical development clearly points to the final conquest of free space. We must be prepared to meet the necessities of this day. The field of space medicine must in time be promoted to eventually cope with the human problems which will most certainly arise.

A Simple Classification of the Present and Future Stages of Manned Flight

By H. Strughold, M. D., Ph. D. [1]

Whenever great inventions or discoveries are made, there is public concern with their potentialities and the length of time required for their full realization. This has been notably true in the application of the rocket principle of propulsion to flight. Rocket flight and space flight symbolize trips to the moon or to Mars. As long as these trips do not materialize, in the public view there is no such thing as space flight. This all-or-nothing attitude is often found in conversations, in radio and television programs, and in print.

It is true that the development of the rocket principle of propulsion is an achievement of revolutionary significance. Yet its complete exploitation will probably follow the pattern of a gradual evolution. The stages of this evolution can be understood best if we examine three factors: (1) the physiological and mechanical properties of the environment, (2) the speeds attained by rockets, (3) and distances they travel over and away from the earth.

ENVIRONMENT

It is well known that the border between the atmosphere and space, in meteorological and astrophysical terms, lies at an altitude of about 600 miles. As an environment for the flyer and the vehicle, however, the atmosphere shows conditions typical of space at much lower altitudes. We encounter within our atmosphere, beginning at 50,000 feet, a region which becomes increasingly space-equivalent with regard to one or more of the conditions, important for manned flight. These conditions are anoxia (50,000 feet), the boiling point of body fluids (63,000 feet), the necessity for a sealed cabin (80,000 feet), meteors (75 miles), and the darkness of space (100 miles). (9)

Above 120 miles we find space-equivalent conditions in almost all respects. The atmospheric region from 50,000 feet (about 10 miles) up to 120 miles may be considered partially space-equivalent, and the region above 120 miles totally space-equivalent, if we ignore certain environmental effects which are caused by the solid body of the earth, its magnetic field, and its own and reflected radiation (8) (fig. 1). Above the 120 mile level, the atmosphere is unrecognizable in manned flight. It is imperceptible to the flyer, although for the astronomer it exists up to 600 miles.

This being true, the rocket-powered plane which has carried man to 90,000 feet and the rockets which have carried animals up to 36 miles (4) have flown in a region which is space-equivalent to a high degree. A two-stage rocket, the WAC corporal mounted on the nose of a V–2, which attained an altitude of 250 miles, was flying under conditions of total space-equivalence even though for a few minutes only. Do not these achievements in very high altitude flying, justify the statement that we have already reached the era of space flight? From the standpoint of the environment we are at present in the partial space-equivalent phase of manned flight.

---

[1] From the U. S Air Force School of Aviation Medicine, Randolph AFB, Texas. Dr. Strughold is head of the Department of Space Medicine.

Presented on March 21, 1955, at the luncheon during the annual meeting of the Space Medicine Association, Washington, D. C.

SPEED

Just as we find levels that are characteristic in the environment around the earth, so too do we find certain characteristic points in the factor of speed. They also mark distinctive stages in the development of flight (Fig. 2).

The first of these is the speed of sound (760 m. p. h. at sea level). The present record in the supersonic speed range exceeds Mach 2. In the higher range of Mach 3 or 4, in horizontal flight, centrifugal forces begin to counteract gravitation to an increasingly noticeable degree. This brings on the phenomenon of decreased weight or subgravity. Theoretically, at about 18,000 m. p. h. or 5 miles per second, in a horizontal flight the state of weightlessness, or the gravity-free state, is finally reached. This speed of 5 miles per second or 8 kilometers per second, where centrifugal force equals the gravitational pull of the earth, is known as the orbital, or better, circular velocity. It is the speed which will enable a craft to circle about the earth in a fixed circular orbit like an artificial satellite. At 7 miles per second or 11 kilometers per second, the craft breaks away from the earth's gravitational pull and escapes into the depths of interplanetary space. It is called the escape velocity.

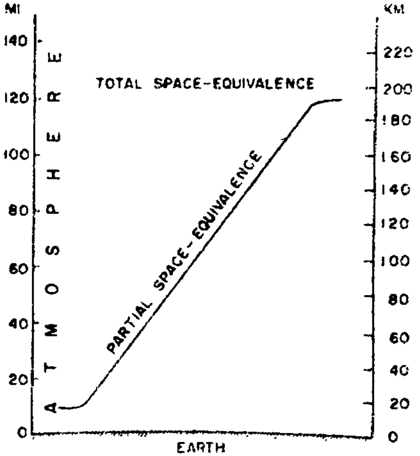

FIGURE 1 —The space-equivalent regions within the earth's atmosphere.

The highest speed so far attained in a two-stage rocket (the WAC Corporal mounted on a V–2) is 1.4 miles per second. This is 30 percent of the orbital and 20 percent of the escape velocity. This is where we stand today with regard to speed The three-stage rocket (1 5) or the atomic rocket (2.7) may bring in the remaining percentage.

DISTANCES

The various stages of flight can also be classified by the factor of the distance they cover The craft may fly from one point on the globe to another point on the globe, in a certain distance around the globe, or far away from the globe into space.

If we combine the factors of environment, speed and distance with their characteristic levels into one picture, we see an evolutionary course in the development of manned flight that looks somewhat as follows: The long distance flights of today take us at subsonic speed, under normal gravitational conditions, in pressurized cabins through the lower regions of the atmosphere from one point on the globe to another distant point on the globe, across a number of time

zones and/or across zones of different seasons in a single day. These are global atmospheric flights. This epoch in flying began when Lindberg crossed the Atlantic Ocean in 1927.

We are now on the threshold of the next stage. Rocket powered planes will take us at supersonic speed under subgravitational conditions and in sealed cabins through the space-equivalent regions of the atmosphere from one point on the globe to another even more distant point in a matter of hours (3). Still

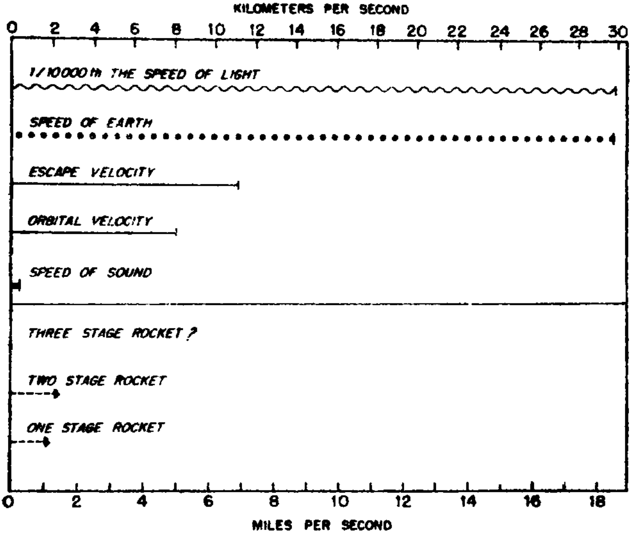

FIGURE 2.—Speed records in rocket flight compared to speed of sound, orbital velocity and escape velocity.

bound to the earth, they will fall into the category of global space-equivalent flight. The precursors of this long distance space-equivalent space flight are seen in the short distance, short time flights of rocket powered planes and unmanned rockets of today. They can be termed local space-equivalent flight.

As soon as the orbital velocity (5 miles per second) is reached, flights of long duration around the globe in a satellite orbit under conditions of zero gravity and in an environment equivalent to space will become possible. But these craft still will operate within the gravitational hold of the earth and will remain within the earth's vicinity. This eventual stage may be called circumplanetary space flight.

The next step will follow as the escape velocity (7 miles per second) is reached. When, one day, a manned rocket leaves the earth, attains this speed and moves freely in space, then we will have arrived at interplanetary space flight or what we may now call "space travel" (1) (5) (6)

This classification (table I) gives us, I believe, a clearly defined and realistic picture of the stage at which we stand today and of the possibilities we may expect in the future. At present we are actually in the first phase of space flight, the phase defined as global space-equivalent flight. Solution of the medical problems in this stage is, therefore, of immediate concern to the physiologist, the engineer, and the flyer. Incidentally, most of the medical problems involved in the final stage (space travel) are encountered in the stage of global space-equivalent flight.

This step-by-step approach to the possibilities of rocket-powered flight by human beings is perhaps more stimulating, and more fruitful for research and develop-

ment, than the all-or-nothing attitude displayed by those who constantly gaze upon remote celestial bodies like the Moon or Mars with a kind of space fascination. The psychological power of attraction of these objects as the final goal, however, must not be underestimated. They are extremely valuable as a background stimulus for our efforts toward advancement of human flight.

TABLE I.—*Classification of developmental stages in manned flight*

	I Global atmospheric flight	II Global space-equivalent flight	III Circumplanetary space flight	IV Interplanetary space travel
Distance	Geographic dimensions	Geographic dimensions.	Vicinity of earth	Interplanetary dimensions.
Environment	Lower atmosphere.	Space-equivalent regions of the atmosphere	Circumplanetary space.	Interplanetary space.
Speed	Sub- and supersonic speed	Supersonic speed	Orbital velocity	Escape velocity.
Gravitational condition	Normal gravitation (1 g).	Subgravity	Zero gravity	Zero gravity.

SPATIOGRAPHY

(ASTRONAUTICAL ASPECT)

By Hubertus Strughold, M. D., Ph. D.[1]

Never before in its history has the imagination of mankind been captivated so much by the concept of space as today, following the rapid progress in rocketry. It is used in a great variety of versions such as near space, outer space, deep space, free space, interplanetary space, cosmic space, blue yonder, and so on. But space is an immensely vast area even within our solar system. From the standpoint of astronautics and especially of space medicine or bioastronautics, we need a specification of just what is meant by these terms topographically and environmentally

Just as the traveler on the earth's surface uses the science of geography for his orientation concerning distance, climate, etc to be encountered on his journey, so does the astronaut need a topographical and environmental description of space, a kind of spatiography for orientation, navigation, the designation of the various kinds of space operations, and the estimation of the medical problems involved. At first glance, it may seem strange to draw borderlines or demarcation lines for subdividing an environment distinguished by emptiness; there are, however, several possibilities

First, the question arises "Where does space begin?" This is the title of a paper published by the writer with H Haber, K. Buettner, and F. Haber in 1951, in which the concept of the functional borders between atmosphere and space was introduced. In this publication, it was shown that the various atmospheric functions for manned flight come to an end at various altitudes, some

[1] Advisor for Research, School of Aviation Medicine, USAF.

even within the lower regions of the stratosphere. The final functional limit of the atmosphere is found at a height of 120 to 140 miles, where the atmosphere aerodynamically terminates though it continues as a material medium up to 600 miles. Expressed in another way, the atmosphere begins to become partially space equivalent at about 10 miles and progresses to total space equivalence at about 120 to 140 miles, as far as the atmospheric functions are concerned. There the laws of aerodynamics lose their meaning (except for objects of enormous velocity) and those of astrodynamics become fully effective. This is the dividing line between space equivalent flight and true space operations, or between the aerodynamically effective airspace and free space. Such is the picture concerning the border between atmosphere and space as seen from the standpoint of space medicine.

Now, what are the possibilities of subdividing, for astronautical purposes, the regions beyond this border—the vast extra atmospheric void of our solar system? First, we can use as demarcation lines the orbital distances of the moon and the planets. Then we speak of cislunar space, translunar space, cismartian, and transmartian space, etc., as Frafft Ehricke has suggested. (Cislunar—on this side; translunar beyond.)

Of special interest from the standpoint of navigation is the gravitational situation in space. The gravitational field of the earth, as of every other body, extends of course to infinity. But for the astronaut, the sphere of predominant gravitational attraction is of most importance. It might be practical to call these gravitational control zones, briefly, gravispheres. The gravisphere of the earth extends to about 1 million miles This is the arena in which satellites are conceivable. Escape velocity thrusts a vehicle eventually out of the earth's gravisphere into the gravitational control zones of other celestial bodies. Thus we arrive at an astronautical subdivision of space based on the extension of the gravitational territories of the various celestial bodies.

Of practical and vital importance to the astronaut are differences in the environmental conditions of space itself. To begin with, the space environment in the vicinity of celestial bodies is different from that in free interplanetary space. It shows some peculiarities caused by the mere presence of their solid bodies, by optical properties of their surfaces and by forces originating in these bodies and extending into space

In the vicinity of the earth for instance, on one side we are protected by the solid body of our globe itself from cosmic rays and meteorites just as we are protected in the lee of a house against rain, hail, or wind. Other peculiarities of the space environment in the vicinity of the earth are the shadow of the earth and the earth's own and reflected radiation, which pose special visual problems and influence the heat balance of a space vehicle.

The forces which cause special regional environmental differences in the space near the earth are those of the geomagnetic field. The magnetic field of the earth strongly influences the influx of corpuscular rays of solar and cosmic origin by channeling them into the polar regions. The density distribution of these ray particles in adjacent space in fact shows considerable variations with the earth's latitudes.

For all these reasons, the space in the vicinity of the earth is somewhat different from open interplanetary space. To emphasize these differences, Krafft Ehricke has introduced the concept of the "terrestrial space" and assumes for it an extension of 1 earth radius or 4,000 miles where they dominate the picture. "Circumterrestrial space" might be another suitable designation. For this region within which the earth's influence upon the ecological qualities of space is distinctly recognizable, it might be advisable to use the term "near space," and for the region beyond, the term "deep space" or "outer space."

But this outer space again shows environmental differences in the various parts of our solar system. These are based on variations in the intensity of solar radiation as a function of the distance from the sun.

A vehicle in the neighborhood of Venus receives about 50 times as much heat per unit of surface area each minute as a vehicle in the area of Jupiter. This is an important factor in the climate control within the space cabin. A vehicle fitted for a trip to Venus is not equipped for an excursion to Jupiter, just as an expedition outfitted to hunt alligators in the jungles of the Amazon could not be sent to hunt polar bears in the Arctic. Any vehicle entering the mercurian space would finally run into a kind of solar heat barrier.

With respect to visible radiation, or light the sky in space is dark everywhere. However, the illumination received from the sun varies considerably. In the orbit of Mercury it amounts to almost 80,000-foot candles while at the remote distance of Pluto, it is only 8-foot candles.

25973—58——80

Finally, the ultraviolet range of solar radiation, which is chemically very active, has strongly influenced environmental conditions on the planets. This is shown by the division of their atmospheres into an inner oxygen belt, and an outer hydrogen belt. The first includes Venus, the Earth, and Mars. The second comprises the planets from Jupiter to Pluto. Spatiographic ecology then, covers two areas; the ecology of space itself, and the ecology of the planets, or planetary ecology.

For manned space operations there seems to be, at least for the time being and in the near future, a limited area in the solar system with regard to the ecological conditions of space itself and the planets, a kind of ecosphere as a function of the distance from the sun and the resulting radiation intensities. This sphere includes the region from Venus to Mars.

We get a dramatic impression of the radiation intensiveness of the sun in both respects by comparing the size of the sun as seen from the various planets. For instance, from the distance of Pluto the sun would not appear larger than the Evening Star, Venus, appears to us on earth.

For hundreds of years, astronomers have been mapping the stars, measuring their distances, and defining their motions. The astronomer performs these magical feats from afar while he sits behind his telescope in a well-tempered observatory, surrounded by the fresh air of Texas or the California mountains. By contrast, the astronaut leaves the life-supporting air of our planet terra and ventures far into space itself in his little terrella. He has to know where he is going, into what physical environment. He needs indeed as guidance a "geography of space," or spatiography, based essentially on ecological considerations concerning space itself and the planets.

Space Medicine and Astrobiology

(Report to be submitted to House Select Committee on Astronautics and Space Exploration, room 214, New House Office Building, Washington, D. C.)

By Hubertus Strughold, M. D., Ph. D.[1]

After a brief outline of the scope of the medical and biological aspects of space flight or astronautics, and the international situation in these fields, the following items, as requested, are discussed.

1. Medical and biological aspects of space exploration.
(a) What research is being done?
(b) What are the areas which need immediate and special attention?
(c) How can research be improved?
2. Education in the medical and biological sector of astronautics.
(a) What is the present status?
(b) How can education be improved?

Scope of research.—As a logical extension of aviation medicine, space medicine studies the medical problems in flight within the space-equivalent[2] regions of the atmosphere and outside the flight effective[3] atmosphere. They are essentially the result of the ecological milieu conditions of space and of the process of motion to, through, and return from the environment of space. The inclusion of the environment found on other celestial bodies into space medical considerations, i. e., viewed from the standpoint of human physiology and survival requires careful studies in planetary ecology in advance.

This astromedical study overlaps with astrobiology which concentrates upon the question of indigenous life on other celestial bodies. All these various studies represent specific aspects of a more general field which can be called bioastronautics.

Originating about 10 years ago, space medicine has made considerable progress in the United States theoretically and experimentally in the laboratory and in flight operations. In the U. S. S. R. the literature in cosmic medicine (as space medicine is called) follows very closely the line of thinking of the West. For several years the Russians have stood on their own feet, and the progress made by them is evidenced by animal experiments in rockets, and by Sputnik II. In 1947 the Russians founded a Department of Astrobotany.

[1] Professor of space medicine and adviser for research, Air University, School of Aviation Medicine, Randolph Air Force Base, Tex.
[2] Atmospheric range from about 12 to 120 miles.
[3] Atmospheric range from above 120 miles.

After this brief introduction, the following comments are made.

1. Medical and biological aspects of space explorations.

(*a*) What research is being done? A great deal of research has been devoted to human engineering of the space cabin as carried out in space cabin simulators. These studies concentrate upon the question of the best suitable artificial atmosphere, and of the most effective air regenerating devices Methods for recording the climatic conditions in such closed ecological systems and for recording the physiological reactions are being developed. For the past 5 years the inclusion of plants in a closed ecological system as oxygen producers and carbon dioxide absorbers has been under study at various places. The effect of increased gravity forces upon the human body is pretty well understood due to studies on centrifuges and on sleds. These have been carried out since 1935. Zero gravity is presently being studied during parabolic flights in jet planes concerning its physiological and psychological effects. The problem of day-night cycling in space operations has been and is being studied theoretically, and experimentally in space-cabin simulators. The same is true for the psychological effects of isolation and confinement. Sealed gondolas have been tested in manned balloon flights up to 102,000 feet. One man has been kept alert in a space cabin simulator for 7 days. The physiological effect of rapid decompression of a space cabin is well understood. Cosmic ray studies have been carried out in numerous balloon flights In experimental astrobiology, terrestrial microorganisms have been studied under simulated Mars conditions. These are some of the most important studies that are underway:

(*b*) What are the areas that need immediate attention?

(1) Methods of recovery and rescue during the critical launching period.

(2) The problems related to reentry.

(3) Studies concerning long-range straight-line landing maneuvers.

(4) Visibility of the earth from great altitudes.

(5) Exposure to zero gravity for longer durations.

(6) Exposure to cosmic rays for longer periods of time.

(7) Simulation of cosmic ray particles.

(8) Experimentation with artificial meteorites and their impact upon a closed cabin.

(9) Search for the most effective air-regenerating means

(10) Continuation of efforts in the development of comfortable pressure suits.

(11) Animal experiments in rockets and satellites as supporting studies for the solution of manned space operations.

(12) Interdynamic medical adaptation to space flight.

(13) Experiments in multi men space cabin simulators.

(14) Telemetering as means of monitoring the space crew.

(15) All medical problems related to the time factor in flight.

(*c*) How can research be improved?

(1) By minimization of red tape

(2) By more and better facilities.

(3) By better opportunities in the form of a sabbatical leave for scientists to visit scientific institutions here and especially abroad

(4) By the creation of a translation and distribution center of foreign literature.

(5) By the introduction of the metric system. (The introduction of the metric system by the Russians during the October Revolution of 1917 is to a great extent responsible for their success in rocketry.)

2. Education in the medical and biological sector of astronautics.

(*a*) What is the present status? For more than 5 years, space medicine has been taught in the various courses for flight surgeons at the School of Aviation Medicine, Randolph Air Force Base, Texas only.

(*b*) How can education be improved? All universities should include in their curriculums several space medicine lectures per semester. Educational films should be used on a broader scale. All pupils in grammar schools and students in high schools should immediately be familiarized with the metric system as this is the only system that—as in nuclear physics—can conveniently be used in astronautics.

In concluding this report, I should like to emphasize that all the efforts at the present time have to be concentrated on achieving a manned orbital flight in the sense of celestial mechanics. A dozen or so revolutions of such a biosatellite will reveal whether or not man can stand space flights over longer durations of time. At present it seems to me that, from the standpoint of medicine, the picture looks rosier than it did 5 years ago, but it should also be emphasized that there are limitations for space operations in our solar system. Space flight in the near and remote future will have to be confined to a certain area in our solar system. All

suggestions for operations beyond this area are not acceptable from the standpoint of space medicine and belong in the department of nonsense. For a realistic approach, factual science combined with imagination and horsesense must be the basis for planning in the exploration of space.

As a final remark I would like to add that space medical studies will be beneficial for medicine in general.

5. Spatiography (Astronautical Aspect), 1958.

The committee stands adjourned until next Wednesday at 10 o'clock.

(Whereupon, at 5:05 p. m., the committee recessed to reconvene at 10 a. m., May 7, 1958.)

ASTRONAUTICS AND SPACE EXPLORATION

WEDNESDAY, MAY 7, 1958

HOUSE OF REPRESENTATIVES,
SELECT COMMITTEE ON ASTRONAUTICS AND SPACE,
Washington, D. C.

The committee met pursuant to call, at 10 a. m., in the caucus room, Old House Office Building, Hon. John W. McCormack (chairman of the committee) presiding.

Present: Representatives McCormack, McDonough, Fulton, Keating, Ford, Brooks, Hays, Metcalf, Natcher, and Sisk.

The CHAIRMAN. The committee will be in order.

The first witness we have is Mr. Loftus Becker, legal adviser of the Department of State. And we are very glad to have you appear before us, Mr. Becker, and I welcome you to the committee.

Also Mr. John C. Cooper, professor of international law, at McGill University.

We like the panel idea. You both will testify and then the members of the committee will have the opportunity of asking either one or both of you questions.

We will hear from you first, Mr. Becker, and then we will hear from you, Professor Cooper.

Mr. BECKER. Mr. Chairman, if it is satisfactory to the Chair, Professor Cooper and I have briefly discussed our testimony and we would like to have him go first, if that would be satisfactory.

The CHAIRMAN. It is perfectly agreeable to the Chair. I was only following protocol. That is all. You represent the State Department. If the State Department wishes to waive its protocol status, that is all right with me.

Professor Cooper, we all know about you. But I would be very happy if you would give your background for the record.

Mr. COOPER. Thank you, Mr. Chairman. May I say in advance that I am very deeply honored to be asked to appear here, to take part in these hearings. Anything that I do have to say is entirely my own personal point of view. And I am not speaking in behalf of any organization, any committee of which I am a member, or any other connections I may have.

STATEMENT OF JOHN C. COOPER,[35] OF PRINCETON, N. J.: PROFESSOR (EMERITUS) OF INTERNATIONAL AIR LAW, McGILL UNIVERSITY

Mr. COOPER. I was born and raised in Jacksonville, Fla., and practiced law there until 1934, except for 2 years spent as a radio officer in the Navy in the first World War. I was chairman of the American Bar Association committee on aeronautical law from 1931 through 1934; and in 1933 represented the United States at Rome as chairman of the delegation to the first conference on private international air law in which the United States participated. I retired from the practice of law in 1934 to become a vice president of Pan American Airways, and, while in that capacity, at the request of the State Department, took leave of absence to become one of the legal advisers on the United States delegation at the Chicago conference in 1944, when the present Convention on International Civil Aviation was drafted. I served as chairman of the drafting committee which reported out about half of the present convention—another drafting committee handling other parts of the convention.

I retired from Pan American Airways in 1946 to become a member of the Institute for Advanced Study at Princeton, because I wanted to do some research and writing on international air law. While at the institute, I was asked to serve as one of the legal advisers to the Air Policy Commission of which Mr. Finletter was Chairman, and later in the same capacity on the Airports Commission of which General Doolittle was Chairman.

When I left the institute in Princeton in 1951, I founded and was the first director of the Institute of International Air Law at McGill University (Montreal), from which I have since retired—I am now an emeritus professor.

This information is given you at Mr. Feldman's suggestion to show that I have had some connection with flight problems, or some of these problems, for many years.

I might also say that some bibliographies indicate that one of the earliest discussions of the problem of the use of space was contained in a lecture I gave at the Naval War College in 1948. Later in a

Home: 1 Armour Rd. Office: 240 Nassau St., Princeton, N J

1951 lecture in Mexico City I raised some of the specific questions I am going to talk about this morning.

Mr. Chairman, the United States, in my judgment, faces grave flight policy decisions in fields other than pure science. These may well affect its future use of space and its relations with other nations similarly engaged.

Four such decisions are of primary importance: (1) the types of flight instrumentalities to be regulated by treaty or statute; (2) the extent upward of our territorial air space; (3) control by international agreement of flight in outer space; (4) the rights of protective action in outer space by the estate below in the absence of effective international agreement.

Each of these questions should be carefully considered by any national Space Agency, acting either alone or in cooperation with those Government departments which may be directly affected by the final policy decisions.

The powers given to the Space Agency should in my judgment be sufficiently broad to accomplish these objectives.

First, as to flight instrumentalities: The present position as to the types of flight instrumentalities regulated by statute or treaty is dangerously confused. This is particularly true of the United States position.

National flight control was first made part of our statutory law by the Air Commerce Act of 1926. Flight in the future by instrumentalities other than balloons, airplanes, and similar devices which require aerodynamic lift was not considered. Aircraft regulated by the act were defined as—and this is of importance—

> any contrivance now known, or hereafter invented, used or designed for flight in the air.

Airplanes, balloons and other types of normal aircraft are of course included. Those guided missiles, such as Snark, which are equipped with air-breathing motors and therefore operate only in the atmosphere as pilotless aircraft, would also meet the statutory definition.

Grave doubt must exist, however, as to how rockets would be classified. They are powered with motors which do not require air intake for combustion. But they do pass through the "air" when used at low altitudes, and operate more efficiently outside the dense atmosphere with its inherent drag.

However, no one could possibly bring presently operated satellites or future space ships within our statutory definition of aircraft. They are designed for flight outside and beyond the "air." They are today not covered by our regulations and statutes.

The situation is in fact even more difficult. The United States is a party to the Chicago Convention of 1944 and is a member of the Council of the International Civil Aviation Organization created by that convention.

And I would say, Mr. Chairman, as a very definite legal point, the annexes to the Chicago convention are not part of the treaty. When adopted by the Council, they are referred to the several States, and unless excepted to, they are normally considered internationally binding. A very difficult situation had to be met at Chicago in 1944 because one of the difficulties to us in the Paris convention of 1919, which prevented the United States from accepting that convention,

was the fact that the annexes were part of the convention. The fact that the international committee created by the Paris convention could amend these annexes had raised serious constitutional questions as to whether the United States could ratify such a treaty which gave to an international organization the power in substance, without reratification, to modify the treaty.

When the matter was considered again at Chicago, a formula was worked out in which the annexes to the Chicago convention are not part of the convention, but are submitted afterward to the states for consideration.

This particular annex was administratively accepted by the United States. It is not technically part of our law, but practically, in my judgment, will be considered binding as to international flight unless something unusual should arise.

In this annex dealing with aircraft, adopted by the International Civil Aviation Organization and accepted by the United States, aircraft are defined as "all machines which can derive support in the atmosphere from reactions of the air." That was the same definition adopted in 1919 in the Paris convention and is, therefore, practically 40 years old; but it is still the only international definition of "aircraft."

This is even more restricted in its scope than the United States Air Commerce Act definition. No type of flight instrumentalities are internationally regulated except normal aircraft types, flying with or without a pilot, and depending for support on aerodynamic lift. Rockets, satellites, and spaceships are thus excluded.

The importance of this becomes evident when the convention itself is examined. I refer to the Chicago convention of 1944.

The body of the convention deals generally with civil aircraft. It includes such provisions as article 12, which empowers the International Civil Aviation Organization to adopt rules for flight of "aircraft" over the high seas with no limit as to height, and article 8 which provides that no "aircraft" capable of being flown without a pilot shall be thus flown over the territory of any state which is a party to the convention without special authorization by that state. Due to the limited definition of aircraft, these provisions will not be applicable to rockets, satellites, or spaceships used even for civil purposes.

But the difficulty is even deeper. Article 3 of the Chicago convention forbids the flight of state aircraft over the territory of another state without special authorization. This is the only existing international agreement on the subject. It might apply to such guided missiles as Snark, but not to those which do not "derive support in the atmosphere from reactions of the air." Certainly article 3 of the Chicago convention does not now prohibit rocket and satellite high altitude flight over the United States because such rockets and satellites are not "aircraft" as internationally defined.

The United States must examine the legal and diplomatic positions created by these narrow, outdated, and confused provisions, and reach definite conclusions as to its future position. Any civil Space Agency should take part in the recommendations when finally made. Future civil as well as military space flight will be directly affected.

Territorial space: The territory of a state is three dimensional. This basic rule which directly affects all international flight must

never be overlooked. National territory includes surface lands and waters within recognized boundaries, areas below the surface, and space above to a height not yet fixed.

The fact that the extent upward of territorial space has never been fixed exactly in our statutes, or the treaties to which we are parties, presents a problem which demands immediate and pressing consideration now that high-altitude rocket and satellite flight has moved from theory to fact. For every state is supreme within its territory. It can unilaterally determine for itself what foreign aircraft or other flight instrumentalities may enter its territorial space and on what conditions. Its jurisdiction within that area is exclusive and its decisions are final, limited only by such exceptions as it may admit by statute, treaty, or other binding national act.

As Chief Justice Marshall said in 1812—7 Cranch 116—all exceptions—

> to the full and complete power of a nation within its own territory must be traced to the consent of the nation itself.

If the area within which the sputniks operated is part of the territory of the United States, our sovereign rights were violated unless it be that the flights in aid of the Geophysical Year were considered to be agreed exceptions to the prevailing rule of law. These questions must not be left long unanswered. The United States must reach a decision as to its position so that the rules applicable to future space flight will be clear.

The past position of the United States can be briefly stated. And this I would suggest, gentlemen, is history very little known. The United States took a very active part in drafting the Paris draft in 1919 although it never became a party to it.

In Paris in 1919 the United States delegates to the Aeronautical Commission successfully proposed the basic position of the "full and absolute sovereignty of each state over the air above its territories and territorial waters, carrying with it the right of exclusion of foreign aircraft." Later we suggested that the "sovereignty of states extends throughout the atmosphere above their own territories," and finally proposed a draft aviation convention recognizing "the full and absolute sovereignty and jurisdiction of every state in the airspace above its territory."

The terms "air," "atmosphere," and "airspace" were being used interchangeably.

I would like to say, gentlemen, if at any time you desire further information on this subject, I was instrumental in unearthing several years ago in the National Archives here in Washington the original report by the delegates to the Paris convention of 1919 where the documents to which I referred are set out in extenso. They have never been properly annotated. They have never been printed. They are tremendously valuable to anybody studying international air law.

The final text of the Paris Civil Aviation Convention of 1919 contained an airspace sovereignty clause following closely the American draft. We signed, but did not ratify, the Paris convention. However, in adopting the Air Commerce Act of 1926, the United States asserted that it has "to the exclusion of all foreign nations complete sovereignty of the airspace over the lands and waters of the United

States." This is still the law, further strengthened by our ratification of the Chicago convention, which provides that every state has complete and exclusive sovereignty over the airspace above its territory.

The Chicago convention has been ratified by most of the flying nations of the world, with the notable exception of the U. S. S. R. However, the Soviet Government has for may years asserted its airspace sovereignty by statute and vigorously enforced regulations.

When the Chicago convention was drafted, flight in space beyond the lower atsmosphere did not exist. I should add I am referring here to flights of normal types of aircraft. A few months before that, the first V–2 flying bombs, or rockets, had been launched. None of us knew at that time the height to which they operated. The trajectory is now estimated at about 116 miles. I can tell you as a matter of unwritten history, that the effect, if any of the flight of the V–2 on the legal conclusions applicable to flight was not put forward nor discussed at Chicago. And article 1 of the Chicago convention dealing with air space sovereignty, which I had the honor to report out as chairman of the drafting committee, was modeled on the Paris convention. It did not take into consideration the fact that there had been a few rocket flights of V–2's prior to the time of the drafting of the Chicago convention.

No factual basis existed for any determination as to whether states in the international community claimed or could exercise sovereignty beyond areas where aircraft could fly depending on aerodynamic lift. But nothing in the Chicago convention precludes the possibility of state sovereignty being extended upward by international agreement or by unilateral force beyond the "airspace." Nor does the convention define what is meant by "airspace."

The United States must face the fact that until the upper boundary of its territorial space has been fixed, and the status fully determined of the area beyond, all future plans for space flight will run the hazard of serious international complications. Any National Space Agency will be directly involved.

Various suggestions have been put forward as to the boundary to be fixed between the territorial space and areas beyond. Some will lead to international chaos. Included in this category are the ideas that no agreement should be made and that each state may claim territorial rights upward as high as it may exercise sufficient command to make its laws effective. The world will then return to the theory that sovereignty depends on power alone—a disastrous outlook for the future

Personally, I believe that an agreement must be reached as to what is "airspace" in the Chicago Convention and national statutes, or preferably that a new convention be adopted fixing clearly the upper boundary of future territorial space irrespective of what was meant in the past by "airspace".

Such solutions might include an agreement that sovereignty should be limited to the height where all possibility of aerodynamic lift ceases, a height, so I am told, of about 50 miles. This might well be a reasonable construction of the Chicago Convention.

Perhaps a more practical boundary might be at the lower limit of the areas in which a satellite can be put in orbit. Professor Menzel of Harvard, a distinguished astronomer, has stated, at a meeting of

the American Academy only a few weeks ago, that studies of meteors entering the earth's atmosphere indicate that the lower limit of a possible satellite orbit is about 70 miles above the earth's surface, defining an orbit as passage at least once around the earth.

Another suggested solution is that territorial space should be extended upward to include all areas where sufficient drag exists to bring the satellite flight to an eventual end. When the facts are available which are being collected now as part of the Geophysical Year, we will know more as to the upper boundary of areas in which satellite flight may prove a potential danger to the earth below due to atmosphere or other sources of drag. And I would say that some of my distinguished scientific friends feel that there is an area of drag due to perhaps cosmic rays or other things than purely atmospheric drag. It is a very difficult problem even to guess at what the result would be.

If the area of territorial space is extended beyond the upper boundary of aerodynamic lift, consideration must be given to an international privilege of innocent passage for rockets, satellites, and space ships engaged in scientific or other civil functions.

In any event, the United States must consider where its greatest boundary is located, that between its territorial space and areas beyond. The decisions to be reached will be aided by scientific research, but involve grave additional political, military, and legal questions in which any Space Agency should participate.

Outer space: The United States must next consider its position as to the political and legal status of flight in space above its territorial space and above the high seas. This decision, when reached, may well govern a large part of the activities of any national Space Agency.

Strong arguments can be made that this outer space should be dealt with as an area somewhat like the high seas where no single nation may exercise exclusive sovereignty. If such an understanding is reached, it should apply also to the moon and nullify any attempt to seize any part of its surface.

It is impossible for me to accept any decision which says that outer space is not subject to seizure by any state and at the same time says that the surface of the moon may be subject to seizure.

I think there is a complete non sequitur.

One able group has gone so far as to urge that the General Assembly of the United Nations should declare that the international community has title to outer space. This is a very radical suggestion. It would infer, I assume, that some international agency would then be created to determine how, when, and under what regulations any state could use outer space even for peaceful purposes. The inherent political difficulties are immediately apparent.

Another suggestion is that any military use of outer space be banned. This would require an effective international control system. It would, I assume, leave all nations free to use outer space for peaceful purposes subject perhaps to minimum regulations, rules of the road, radio and other communication arrangements, acceptance of national responsibility for damages by collisions or otherwise, and similar provisions. With such an international agreement, man would have a better chance to live in peace.

Even this brief statement shows how vital it is that the United States reach a decision as to its own policy. Careful consideration

must also be given to the question as to whether our course of dealing with our satellite flights and those of the U. S. S. R. has or has not already committed us to the position that outer space is beyond the territorial jurisdiction of any state and is free to all flight. I refer, of course, to the fact that no permission was asked of any state before the satellites were launched, and no protests appear to have been made by any state overflown. If the organization of the International Geophysical Year is deemed tacit consent to the satellite flights without creating precedents for the future, perhaps everyone should be so advised. In any event, a future National Space Agency will be directly affected.

Protective action in outer space by the state below: Years may elapse before complete international agreement exists as to regulation of outer space flight. Even when agreement is reached in theory, experience may show that regulation is not effective in protecting the state below from outer space attack or other danger. In either case, a state below may find itself threatened by the use of outer space above it. If so, has it any right to take defensive and protective action in the areas above and beyond its declared territorial space?

The political and legal aspects of this vital problem should be given urgent consideration. The precedents as to the high seas must be studied with great care. A decision must be reached as to whether principles exist capable of application in outer space.

The rights of national self-preservation and of self-defense are unquestioned. The only problem is whether they are applicable in cases other than definite armed attack.

In 1804, Chief Justice Marshall, in the case of *Church* v. *Hubbart*, discussing protective action on the high seas, stated that the power of a state—

> to assure itself from injury may certainly be exercised beyond the limits of its territory.

In 1914, 110 years later, Secretary of State Root relied upon the same principle as the basis of the Monroe Doctrine, namely—

> the right of every sovereign state to protect itself by preventing a condition of affairs in which it will be too late to protect itself.

I know of no statement of the law that is more accurate in a few words than that statement.

In 1941, President Franklin Roosevelt defended the establishment of defense zones off our coasts before we had entered the war, saying:

> In the waters which we deem necessary for our defense, American naval vessels and American planes will no longer wait until Axis submarines lurking under the water or Axis raiders on the surface of the sea strike their deadly blow first—our patrolling vessels and planes will protect all merchant ships, not only American ships but ships of any flag, engaged in commerce in our defensive waters.

Even more in point is the establishment by the United States in 1950 of the "Air Defense Identification Zone" around our shores. This is curiously very little known. Canada has a similar series of air defense zones.

It is fully conceded that the airspace over the high seas is not territorial space and enjoys the same international status as the high seas themselves. Yet the United States did not hesitate to establish by executive order regulations to prevent unidentified aircraft approaching our shores from the seas. The regulations require among other

things that foreign aircraft must report to an appropriate aeronautical facility when the aircraft is not less than 1 hour and not more than 2 hours average cruising distance via the most direct route from the United States. This is a clear application of rights of self-preservation and self-defense effective outside the territory of the United States and within international space.

Certainly the proposed Space Agency will desire to study these and similar problems affecting the flight of unidentified and potentially dangerous flight instrumentalities over our surface territory but beyond our territorial space.

The examples just given of political and legal questions which are "problems of flight within and outside the earth's atmosphere" as stated in the title of the bills now under consideration—are merely illustrative of the many questions not necessarily included in scientific research. It is respectfully suggested that the functions of the proposed National Aeronautics and Space Agency be widened so as to permit research affecting flight problems other than those which are strictly included as "aeronautical and space sciences." If this is done, the advice of the Agency to other branches of the Government will, it is believed, be made much more comprehensive and useful. Certainly an opportunity will be afforded for a broad, unified analysis of policy affecting both national and international flight within and without the earth's atmosphere.

The CHAIRMAN. Thank you very much, Professor Cooper, for your original statement which is very penetrating and challenging.

We will now hear from you, Mr. Becker.

STATEMENT OF LOFTUS BECKER [36] LEGAL ADVISER, DEPARTMENT OF STATE

Mr. BECKER. Mr. Chairman, on behalf of the Department and on my own behalf, I would like to express my appreciation for the opportunity to appear before you.

I am a native of Buffalo, N. Y. I practiced law in Honolulu and in New York City after my graduation from law school in 1936; and with three exceptions I have merely engaged in the practice of law. One was a departure for the Army during the war. The second was a period of some 2½ years as deputy for intelligence for Gen. Bedell Smith. And finally my present position as the legal adviser of the Department of State.

I said I graduated from law school in 1936. You may have noted that was 2 years after Professor Cooper retired, and therefore, I cannot assume to have the great background and experience he has. My knowledge of the subject on which I am talking today has been acquired through forced feeding in the way they feed geese in order to make their livers somewhat more tasty. I seem to be full of the subject.

---

[36] Becker, Loftus Eugene, govt ofcl.; b. Buffalo, Apr 29, 1911, s Rueben Ezra and Helen Mary (Gilmartin) B., A B magna cum laude, Harvard, 1932, LL B magna cum laude, 1936, student U. Vienna, 1932-33; m. Ellen Vander Voort, Dec 25, 1933; children—Susan Elizabeth, Gretchen Ellen, Loftus Eugene Admitted to T. H. bar, 1936, N Y, 1940, asso Anderson, Marx, Wrenn & Jenks, Honolulu, T. I A, Washington, 1951-53, Washington partner Cahill, Gordon, Reindel & Ohl, 1953—. Served U S Army, 1942-45. Mem. Am., N. Y. State, T. H., N. Y. C bar assns. Club University. Home: Tempo Farm, Saul Rd., Kensington, Md Office: 1000 Vermont Av., N. W., Washington.

What I shall endeavor to discuss today is first to attempt to correct what I, and I believe my Department, regard as certain misconceptions with respect to international law in the space field, and then so far as I am able to do so to state the position of the Department on some of these matters of international law relating to space.

In doing the latter, I may sometimes sound like the witness who said, "I know nothing, and I shall tell all."

And when I do that, I shall endeavor to give you the rationale of why the Department has not taken a position on some of these issues, although many commentators—and Professor Cooper is not among the number of those commentators—have strongly urged that they do, and have said there is an emergency of some sort in this field.

The first question I would like to discuss is: "Is there any accepted principle of international law bearing upon outer space." I think that there is a great deal of misconception on this point, because I have read a number of articles in which it is stated that the only international agreement relating to space or the atmosphere is the Chicago convention of 1944. And there is no international law with respect to space outside the atmosphere.

Well, I regard that as incorrect because of the specific provisions of article 51 of the United Nations Charter. Under that provision, each of the members of the United Nations reserved their inherent right to defend themselves against armed attack. It is their inherent right of individual or collective self-defense.

Now, the origin of an armed attack against the United States, or the particular point in space through which it would have to pass in order to reach the United States, or one of its collective security partners, is completely immaterial.

The United States is prepared at all times to react to protect itself against an armed attack, even though that attack might originate in territory which is unquestionably subject to the sovereignty of another state.

A fortiori the United States would be prepared to react to protect itself against an armed attack either originating in outer space or passing through outer space in order to reach the United States. And Professor Cooper has already noted the instances in which the United States has stated that it is prepared to protect itself even though the activity threatening the United States is engaged in on the high seas which are common to all nations.

Now, the point I want to make is that if and when the United States takes such action, it is not merely acting unilaterally. It is exercising a right which it has under international law. Because international law in the last analysis is what nations will agree to. And the inherent right of individual and collective self-defense has been agreed to in the United Nations Charter.

Now, secondly, there is another error that I seem to have seen in a number of articles. And that is that we do not have any right to protest or take any action with respect to satellites because of the events relating to the International Geophysical Year. The facts are these: the arrangements with respect to the International Geophysical Year were not made on an intergovernmental basis. They were arrangements made between scientific bodies in a private capacity. It is true that certain governments, including the Soviet Union and the United States, announced in advance that during the Inter-

national Geophysical Year they intended to place objects in orbit around the earth. And it was also stated in connection with those announcements, if my memory is correct, that the purpose of these satellites would be for scientific investigation.

It follows, therefore, that the only conclusion that can be reached with respect to the arrangements regarding the International Geophysical Year—and I should say at this point, as Professor Cooper has already stated, that no nation protested any of these announcements—is that there is an implied agreement that for the period of the International Geophysical Year, it is permissible to put into orbit satellites designed for scientific purposes. Once the year is over, rights in this field will have to be determined by whatever agreement may be reached with respect to such objects.

The third question I would like to call attention to is: Has the United States recognized any top or upper limit to its sovereignty?

Again a number of commentators, other than Professor Cooper, have asserted without qualification that the sovereignty of the United States ends with the outer limits of the atmosphere, and that space outside the atmosphere is either free to all or, as has already been noted should possibly be conceded to be within the sovereignty of one or another international organizations.

Well, the answer to the question I have posed is "No." The United States Government has not recognized any top or upper limit to its sovereignty. And that is entirely aside from article 51 of the United Nations Charter and any limitations that may be inherent in that, such as armed attack.

Now, it is true, as a number of commentators have emphasized, that in such international agreements as the Chicago convention of 1944, the parties thereto recognize that each of them "has complete and exclusive sovereignty of the airspace above its territory."

Now, from this some commentators have inferred a negation of the principle that any state has sovereignty over space outside the airspace above its territory.

I cannot agree that the significance of international agreement upon a principle such as this can be evaluated without regard for the context in which it was made the subject of agreement. To stipulate that a state has complete and exclusive sovereignty within certain limits is not to say that it has no rights above those limits. The only reasonable inference from such a statement is that no agreement has been reached as to what, if any, rights may be recognized above such limits.

It is important to note that there is nowhere in the Chicago convention of 1944 or other international agreements comparable thereto any definition of what is meant by the term "airspace."

A number of those who have commented on what should be the law of space have suggested definitions for this term. I do not wish to take, nor has the State Department ever officially taken, a definitive position as to how this term "airspace" should be defined. I think it important to know, however, that one of the suggestions made in this regard is that the airspace should be defined to include that portion of space above the earth in which there is any atmosphere. I am informed that astronomically the earth's atmosphere extends 10,000 miles above its surface. Just before I came over here this morning I received a phone call in which it is reported that there is

an article in the Times this morning in which one investigator claims there is evidence of atmosphere anywhere from 40,000 to 200,000 miles away from the earth's surface.

Well, while we haven't taken any position on the question, I think you will appreciate from these facts that it would be perfectly rational for us to maintain that under the Chicago Convention the sovereignty of the United States extends 10,000 miles from the surface of the earth, an area which would comprehend the area in which all of the satellites up to this point have entered.

At any rate that type of definition would afford us enough elbowroom for discussion.

Now, it is also important to note that although the United States in its domestic law, as well as agreements such as the Chicago Convention, has plainly asserted its complete and exclusive sovereignty over the airspace above its territory, it has at no time conceded that it had no rights in the higher regions of space.

One rationale for this position which seems to me self-sufficient was that the United States had no need to define its position with respect to what rights, if any, it might possess outside the earth's atmosphere until such time as mankind had demonstrated a capability of existing outside the atmosphere.

Even after such a capability is demonstrated, there will be no imperative requirement in international law that the United States make any claims of sovereignty in order to protect its rights.

A very apt analogy is afforded by the Antarctic. There, for many, many years, the United States has been engaged in activities which under established principles of international law, without any question whatsoever, created rights upon which the United States would be justified in asserting territorial claims. That is to say, claims to sovereignty over one or more areas of the Antarctic.

Notwithstanding this fact, the United States has not asserted any claim of sovereignty over any portion of Antarctica, although the United States has at the same time made it plain that it did not recognize any such claims made by other states.

Nontheless, the United States has been consistent in asserting that under international law and practice its activities in the Antarctic Continent have entitled it to rights in that area which it has at all times expressly reserved. It is the position of your Government, and I believe one well founded in international law, that the fact that the United States has not based a claim of sovereignty over one or more areas of Antarctica, upon the basis of the activities it has engaged in there, in no way derrogates from the rights that were established by its activities.

So, too, in outer space the United States has already engaged in activities which, it could be asserted, have given to it certain rights and distinguished from those states who have not engaged in such activities. Up to this time, the United States has made no claims of sovereignty based upon such activities.

As in the situation with respect to Antarctica, this should not be interpreted as any concession of any kind whatsoever on the part of the United States that its activities have not given it certain rights in space which in turn could be relied upon as the basis of a claim of sovereignty.

Now, I would like to turn to the question of whether or not the law of space should be codified at this time. I may say in that connection that I returned very recently from Geneva, Switzerland, where 82 nations were engaged in an attempt to codify the law of the sea.

Now, man has been traveling on the sea for thousands of years. And a certain number of rules with respect to travel on the sea and what might be done there have been well recognized in international practice for hundreds of years. The conference lasted for 10 weeks. It was the subject of the most bitter negotiation that I have ever seen. This is with respect to an area of international law where many, many facts are known.

Now what has been done with respect to the law of space up to this date by this country?

The President, the Secretary of State, and Ambassador Lodge in the United Nations, have several times suggested—and they sometimes made the suggestion directly to the U. S. S. R., which to date is the only other state that has demonstrated a capability of placing objects in orbit in space—that we consult with the objective of insuring that mankind's activities in space be devoted exclusively to peaceful purposes. These proposals have included any and all activities in space, whether or not they involve putting an object in orbit.

To the extent envisaged by these proposals, we believe that the sooner that agreement is reached, the better.

As you know, the development or the tendency of development of the common law as it is applied in the United Kingdom and the United States and a number of other countries has been on a case-to-case basis.

Speaking very generally, it has been felt that the soundest way to progress in the extremely complex field of the law is by means of specific decisions on specific questions presented by specific fact situations. Even in those states which applied the principles of the civil law, it is recognized that a body of law can only be created upon a broader body of ascertained fact.

Moreover, there are very great risks in attempting to transmute a body of law based upon one determined set of facts into a body of law with respect to which the basic facts have not been determined.

Accordingly, we are inclined to view with great reserve, any suggestion that the principles of the law of the sea should, prior to the ascertaining of many more facts with respect to conditions in space, become the law of space.

Basically it is the position of our Government that the law of space should be based upon the facts of space, and that there is very much more that we have to learn about the conditions existing in space before we shall be in a position to say what shall be the legal principles applicable thereto.

Now, let me speak for a moment on the significance of a definition of the airspace. It has many times been suggested that it is imperative that at the earliest possible moment we shall have an internationally agreed upon definition of airspace. This is related to the suggestion that such definition is requisite in order to delimit areas of national sovereignty. I believe from what I have already stated it will be apparent to you that I do not share in this view, nor

25973—58——81

has the United States Government ever conceded that its sovereignty upward was restricted to the airspace above its territory.

There are other aspects of this question with respect to which the significance of this dividing line may be less important than has heretofore been asserted. Public announcement has been made of an X-15, which is designed to operate both inside and outside the earth's atmosphere as defined, at least, by some of the commentators. Moreover, all objects which orbit around the earth, whether they do so within or outside the atmosphere, or partly within and partly outside the atmosphere, have characteristics of operation which distinguish them sharply from other objects which may, for a period of time, pass through space.

As you are undoubtedly well aware, a number of systems of private law relate to the characteristics of the activities upon which one is engaged.

For example, in our own law we have one set of rules applicable to the activity of mining; another applicable to the extraction of petroleum and like materials; and still another applicable to subsurface waters; although all three activities in general relate to man's actions or interests below the surface of the earth.

Here again, one of the possibilities to which we shall have to give serious consideration is whether the performance of a particular space vehicle is sufficiently distinguishable so as to justify applying to it a set of rules which are different and distinct from those we apply to other space vehicles having different operating characteristics.

To take an analogy from the law of the sea, while there have been certain principles applicable to all seagoing vessels, there has always been a distinction between the rules applied to sailboats and those applying to boats propelled by one or another method of mechanical propulsion.

Another issue that has been raised with respect to space is the status of property rights there. A number of commentators have stressed the necessity of developing some internationally recognized set of principles of property rights applicable to space vehicles. Two of the questions frequently raised are, first, as to the right of the state beneath—the subjacent state—to protect itself from injury from such a vehicle landing on its surface or its inhabitants, or, second, as to the right of such a state to damages for injuries resulting from such activities.

Another question in this regard which received a certain amount of attention in the press when the Soviets claimed that a portion of their Sputnik No. 1 had landed in some unidentified portion of the United States, is whether or not the state which initiates the flight of a space vehicle retains a property right in that vehicle in the event that it comes to earth again.

Now, even though there isn't any generally accepted international code regarding space vehicles as such, I would suggest that existing international law and domestic law provide a set of principles which could be considered as applicable until such time as we find it necessary to recognize specialized principles.

With respect to the right of a satellite or a missile to pass through the airspace of the United States, we have to take account not only of the Chicago Convention and its definitions of "aircraft," but also the domestic law of the United States and its definition of "aircraft."

In our domestic law, just as in the Chicago Convention we assert complete and exclusive sovereignty over the airspace above our territory. Now the definition of aircraft in our domestic law is considerably broader than that contained in the Chicago Convention because both in section 9 of the Air Commerce Act of 1926 and in section 1, subsection (4), of the Civil Aeronautics Act of 1938, aircraft is defined as follows, and I quote:

> Aircraft means any contrivance now known, or hereafter invented, designed for navigation of or flight in the air.

As you can see that is an extremely broad definition—"designed for navigation of or flight in the air."

By that apposition, the indication is that you can navigate in the air without flying in the air in the sense of being suspended by the air.

I would take the position that that provision, regardless of any provision of the Chicago Convention, would cover a missile or any object regardless of the method of propulsion.

Accordingly, our domestic law would apply as to transit of our airspace by any such object. We have made it perfectly plain that other nations are not entitled to invade that airspace without the consent of the United States Government.

Assuming that the problem of reentry has been overcome, so that a space vehicle does not disintegrate before it returns to earth, such a vehicle must, of necessity, pass through the airspace of the United States in order to return to earth if it comes in over the geographical area of the United States, or over our territorial waters

It is a recognized principle of international law that the sovereignty of a state with respect to the airspace over its territory and its territorial seas is complete and exclusive. That means that the vessels of another state, including those which are unmanned as well as those that are manned, are not entitled to enter upon such airspace without the permission of the sovereign state.

If the permission of the subjacent state is to be obtained, it may be conditioned by undertakings with respect to liability for any damage that may result therefrom.

If it is not obtained, the tortious nature of the entry upon the airspace of the subjacent state would seem to make the initiating state a guarantor with respect to any damage resulting from its unjustified activity.

As respects the ownership of a space vehicle returning to earth, some commentators have suggested that at least as respects unmanned space vehicles, the appropriate analogy is a bullet; ownership of which is abandoned by the act of firing. An alternative rationale would be that any such vehicle entering the airspace of a sovereign state without the latter's permission should be placed in the category of smuggled goods which may not only be confiscated upon discovery but with respect to which action may be taken outside the territory or the territorial waters of the state in which they are to be introduced.

I refer there to the type of precedents that Professor Cooper referred to, that we reserve the right before an object or vessel has entered within our sovereign area to take measures to see that it does not so enter.

Thank you, gentlemen.

The CHAIRMAN. Professor Cooper, on your first page I note you said, "The powers given to the space agency should be sufficiently broad to encompass these objectives."

And on your last page, page 10, it is respectfully suggested that the—

> functions of the proposed international aeronautics and space agency be widened so as to permit research affecting flight problems other than those which are strictly included as "aeronautical and space sciences."

What language do you suggest could be included?

Mr. COOPER. I simply put that before the committee as consideration for a principle. I have no language to suggest.

I had a conflict in my own mind, having been a scholar and having been a rather technical lawyer at times. As a scholar, if I were acting as counsel for such a space agency, I would certainly wish that space agency had a reasonable opportunity to investigate cognate problems merely in addition to pure scientific questions.

As a technical lawyer, I was rather afraid that the language in the bill under the heading "Functions" delimited rather strictly the power of the space agency, and that some challenge might be given as to its right to expend funds for any research that was not pure or applied science. I simply wanted to bring that before you from my own personal point of view as something the committee might want to consider.

Mr. FULTON. We have the bill right here.

Mr. COOPER. I can point out the section.

This is the bill 11881. It was the provision appearing on page 5:

> The agency shall develop a comprehensive program of research in the aeronautical and space sciences, (2) plan, direct, and conduct scientific studies and investigations of the problem of manned and unmanned flights within or outside the earth's atmosphere with a view to their practical solution.

It seemed to me that both of those phrases were somewhat narrower than the declaration of policy which said that the general welfare and security of the United States required the adequate provision to be made for research into and the solutions of the problems of flight within and outside the earth's atmosphere.

That is much broader language than the functions which I, as a lawyer, thought had been delegated to the agency.

That, however, is a matter, sir, on which I would not consider myself an expert. Perhaps I am entirely incorrect, but I did wish to bring it to your attention.

The CHAIRMAN. You recognize, of course, like Mr. Becker, that this is a matter of long-range study, consideration, and action.

Mr. COOPER. That is exactly my point, sir. It seems to me there are problems in addition to those of pure science which are involved.

The CHAIRMAN. And Mr. Becker has in his statement properly tied up the whole question to security of our country.

Mr. COOPER. I agree. That was the purport of Mr. Becker's testimony, as I heard it.

The CHAIRMAN. As I analyzed your views and Mr. Becker's views, representing the State Department, there isn't much basic difference.

Mr. COOPER. I would say, sir, that I have had the pleasure of discussing these problems with Mr. Becker many times. I think our views are strikingly similar.

Mr. BECKER. I concur in that statement.

The CHAIRMAN. How did the Paris Convention and Chicago Convention come into being? Was that governmentally sponsored?

Mr. COOPER. The Paris Convention, sir, was an outgrowth of the Paris Peace Conference. In 1910 there had been an effort in Europe to draft a convention for the international regulation of civil flight. That conference drafted an almost complete convention. It broke down on some rather technical disputes between the German and the British delegation as to whether or not different rules could be made applicable by the state below for its own aircraft and foreign aircraft. Both the French Government and the British Government, during the war, did a great deal of work on the question of international control of flight after the war.

When the peace conference assembled in Paris, it was decided to assemble an aeronautical commission to deal not with the problems of the peace treaties, but to deal with the future control of international flight after the war. The United States delegates were two distinguished officers, one naval and one military. They had had no prior warning that this commission was to be set up. It is purely amazing the work that this hastily assembled delegation did.

And as I pointed out in my statement, they took a very active part in the determination of principals which should be applicable to civil flight.

One member of the American delegation was actually on the drafting committee which brought in the Paris Convention. The Paris Convention was signed by practically all of the Allied Powers, including the United States.

From statements made to me by a long-deceased member of the Senate, there are two reasons why it failed of ratification. The ordinarily assigned reason is that it referred indirectly in the convention to operations under the League of Nations, or something like that. In other words, it was tied up to some extent with the League of Nations.

The direct technical question which I mentioned this morning, so I was told by the then chairman of the Foreign Relations Committee, was that—I am trying to remember the name—who was the Senator from Nevada who was chairman of the Foreign Relations Committee for years.

Mr. McDONOUGH. Senator Pitman.

Mr. COOPER. Yes. He told me personally that the major reason, in his judgment, why the Foreign Relations Committee didn't accept the Paris Convention was that it constituted a delegation to the international regulatory body set up under the convention power to amend the annexes. And the annexes in the Paris Convention were part of the convention itself.

The Chicago Convention was drafted at an international diplomatic conference held in Chicago called by the United States at which were present all of the Allied Powers and a number of neutral powers. There was a long discussion in the United States delegation about this very point that I have just mentioned. And it was for that reason that the United States took the very vigorous position that the annexes to the Chicago Convention were not to be considered as part of the convention, namely that the International Civil Aviation Organization was not being delegated power to amend the convention without its being reratified by the United States.

I am not sure that that is material here, sir.

The CHAIRMAN. In other words, it might be a guidance to such nations as wanted to be guided by it, in whole or in part.

Mr. COOPER. There are very elaborate provisions applicable to the International Civil Aviation Organization under which they adopt annexes and distribute them to the member states. And they request that member states within a certain number of days, advise them whether they reserve on any of those provisions.

The CHAIRMAN. On page 6 you stated that "an agreement must be reached as to what is 'airspace' in the Chicago Convention and national statutes, or preferably that a new convention be adopted fixing clearly the upper boundary of future territorial space irrespective of what was meant in the past by 'airspace'."

Was the establishment of the Paris Convention on a governmental level?

Mr. COOPER. Yes. With reference to article 1 of the Chicago Convention which is the airspace sovereignty clause, it was copied almost verbatim from the Paris Convention. And the reason it was done was this: There was already a lot of international flying, military and otherwise, and some international agreements, prior to World War I. Some of the people at Chicago felt—and I concurred—that if we put new language as to state sovereignty in the Chicago Convention that had not been in the Paris Convention, someone will say, "What is the meaning of these changes?" and therefore, unanimously the Chicago Conference accepted the sovereignty statement in article 1 of the Paris Convention, which is a very interesting document.

It says, Mr. Chairman, that every state—not every signatory state—but every state has complete and exclusive sovereignty in the airspace over it. Which means that they accepted and approved an already-prior existing rule of customary international law—they said we are simply saying that every state, irrespective of this document now has sovereignty, complete and exclusive in the airspace.

It was not a mutual exchange, a grant of new rights and privileges. It said just as Paris said, "every state has." The Paris Convention used the old terminology that "every power has." We changed it in Chicago to "every state has."

The CHAIRMAN. In other words we all agree. But we have the individual right of veto?

Mr. COOPER. I think, sir, that everybody agrees there is sovereignty in the airspace. My worry is "what is the airspace?"

The CHAIRMAN. Well, I am not passing on the enunciation of that principle. But I mean that carrying it into operation gives to every nation the right to its own action.

Mr. COOPER. I would say, sir, that the very few states which have not ratified the Chicago Convention have similar language in their own statutes. For example, the U. S. S. R. has had since about 1921 very strong statutory statement that the U. S. S. R. claims sovereignty.

The CHAIRMAN. Of course in connection with any such conference or international meeting, the State Department, of course, would play a very important part in connection with our Government.

Mr. COOPER. I would say, sir, that I have had the pleasure of assisting the State Department in some past years. And I know that it has always had these matters in mind.

I would think it unfortunate if any department, but the State Department, had the final say-so.

The Chicago Conference was actually called by the President at the request of the Secretary of State.

The CHAIRMAN. So that while the new space agency might have a place therein, it would be naturally secondary to that of the State Department.

Mr. COOPER. Certainly, sir.

The CHAIRMAN. Now, I notice on page 6 of your prepared statement, you mention the theory that no agreement should be made and hence each state may claim territorial rights up as high as it may exercise sufficient command to make its laws effective. The world would then return to the theory that sovereignty depends on power alone—a disastrous outlook for the future.

In part, if I read your mind correctly—and if not, I wish you would clarify it—I would infer that one of the thoughts running through your mind is that we are entering into some new adventure. Some of the things that can be accomplished we know. Others we don't know. So if any international agreement can be made on utilizing space for peaceful purposes, the attempt should be made before any two or more nations get into a serious competition on the military level for the use of space for military purposes.

Would that be a fair inference?

Mr. COOPER. That is entirely fair, sir. I argued this point at some length a number of years ago, pointing out that if you accepted the theory that sovereignty ran as high as you could grant, the small states would never have any future use of space, and you would have a competitive world that personally I would dislike as a peacetime operation.

The CHAIRMAN. What importance do you attach to the establishment of a space agency in our Government giving it adequate powers on a high decision level, the power to carry out decisions? What importance do you attach to such an agency?

Do you think we need one?

Mr. COOPER. I would say, Mr. Chairman, that I had an indirect part in the conferences out of which the Civil Aeronautics Act of 1938 grew. I happened at that time to be a member of the industry committee which was discussing those problems with the Government. I feel about this problem much as I did then; that regulation on a sound basis for such an evanescent thing as flight is highly advisable.

Also I feel that the problems of the peaceful use of space—a problem in which I am primarily interested—I have no military connections—that the United States could, by organizing such an agency as I read in your bill, put itself in the position to think a long way ahead of how the United States and man generally could take advantage properly of this new method of transportation without engaging in what I would deem unfortunate and maybe catastrophic international competion.

I think that this space agency could analyze the entire field and say, "Well, perhaps the time has now come." And I will give you a concrete example.

Such an agency, a space agency, might say, "Perhaps the time has now come when we can carry the mail rom New York to London by rocket. If so, why not do it?"

In other words, I think that you have a whole new problem to deal with. And I think that a new agency could very aptly do it provided,

of course, that it is worked into the general framework of our rather complex Government.

The CHAIRMAN. Have you any opinion as to whether a new agency should be on a commission form or a single head.

Mr. COOPER. I have none whatsoever, sir.

The CHAIRMAN. Both of you gentlemen, as all other witnesses, have permission to edit your testimony. Upon looking over, particularly, your extemporaneous answers and questions you might want to clarify. You have permission to do so.

And if you have any language you want to suggest in connection with what I have referred to on page 1 and page 10 of your testimony, we welcome any such suggested language.

Mr. COOPER. Thank you very much, sir. I will discuss that matter with Mr. Feldman, your counsel, and perhaps I might have some suggestions to make.

I have none in mind at the moment.

The CHAIRMAN. Mr. Hays.

Mr. HAYS. I believe I will direct my questions to Mr. Becker, since the question is inspired by his testimony. Professor Cooper will probably want to make a comment on it.

First, let me say that your statement was exceedingly helpful. The committee, I am sure, all appreciate the study you have given to this problem. And it is very enlightening to me. Now, as I understand it, the Chicago Convention—its usefulness in this situation is limited somewhat by the fact that they were contemplating only control of airborne vehicles.

Mr. BECKER. That is a construction of their definition of aircraft. It does not specifically limit it to airborne vehicles, although it might be argued that it should be so construed.

Mr. HAYS. Do you mean that rockets were not necessarily out of mind—that is, speaking of airborne, the power or propulsion, depending on the presence of atmosphere. The rocket that went outside the atmosphere was just not in the contemplation of the Chicago Convention, was it?

Mr. BECKER. Well, I don't know the answer to that question, sir. If you recall, the convention was entered into in December of 1944. In September of that same year, the Germans had begun firing the V–2 rocket, which went, as I understand it, about 115 or 116 miles out from the earth before it returned to the earth. And as you also recall, there was a remarkable degree of publicity with respect to that fact inasmuch as they were landing on London. So they could have had that type of thing in contemplation. It is possible they did not. The language they used was certainly not as good as the language that is used in our domestic law in that regard.

Mr. HAYS. I think your answer proves very well the complexities of this whole problem. I anticipated there would be a categorical answer. I hadn't realized that you had that basis for the answer.

At any rate, it is fair to say that there is some help in the experience of the Chicago Convention in these problems.

Mr. BECKER. That is right.

Mr. HAYS. But we have to assume for administrative purposes and for legal purposes that a new beginning would be substantially necessary.

Mr. BECKER. I concur in that statement, Congressman Hays.

Mr. HAYS. For the reasons we made?

Mr. BECKER. Yes.

Mr. HAYS. One deals with the area covered by the blanket of air, and the other outside.

Mr. BECKER. I not only agree with that, but as you may have gathered from my statement, I recommend that we approach this problem as an entirely new problem and make our decisions on the basis that we have a completely new set of references to deal with.

Mr. HAYS. The Soviet Government is a part of the Chicago Convention.

Mr. BECKER. No, it is not.

Mr. HAYS. Has there been any overture to them to become a part of it?

Mr. BECKER. I am aware of none.

Mr. HAYS. That means, then, that there are no Communist governments a party to it?

Mr. COOPER. Mr. Hays, if I can give you some past history: When the Chicago Conference was called by the Secretary of State, the Soviet Government accepted the invitation to attend the Conference. Its delegation was actually en route by air to the conference and had reached a point somewhere in Canada, en route to Chicago. I remember very vividly sitting in a meeting in the State Department of the United States delegation preparatory to our going to Chicago, when we were advised by one of the assistant secretaries that they had just been notified the Soviet delegation had been recalled and would not take part.

So, they were invited by the United States originally to take part, but did not actually participate in the Convention and have never signed it.

Mr. HAYS. Thank you very much. I was impressed by what you had to say about treating space law as distinctive from sea law. And it is true, isn't it, that international law with reference to the sea tends to become rather rigid. How is international law changed and what will we run into in this matter of law governing space with reference to amendments?

Isn't international law very difficult to change? You have no legislature to change it.

Mr. BECKER. I will give you a very good example of that, Congressman. And it comes out of this Geneva Conference on the law of the sea. Certainly by the end of the 19th century, it was very well settled that each state had a territorial sea in which it could exercise sovereignty out 3 miles from its coast. Since that time a number of nations have made broader assertions unilaterally as to their right to have a territorial sea having a broader area.

Some have claimed 6, some claimed 12, and some have claimed up as far as 200.

One of the basic issues at Geneva was whether or not that 3-mile rule should be changed; because unless there was agreement to change it, it would not be changed, and the United States has consistently taken the position that notwithstanding the fact that, oh, some 25 percent of the nations claim a broader territorial sea, that is not effective to make a change in the customary international law.

We received a vote of 45 to 33 to a compromise proposal made by the United States at Geneva under which there would be a 6-mile

territorial sea with a contiguous 6-mile zone in which the coastal state would have the exclusive right to control fishing, subject, however, to the historical rights of those who had fished in that outer 6 miles for the last 5 years.

We had a majority—45 to 33—but the rule of the conference was that no principle was adopted unless by two-thirds vote.

As a result, and notwithstanding the proposals that were made there, we have made it plain that we regard the 3-mile territorial sea as international law as of this date. Had two-thirds adopted, or had two-thirds voted in favor of that compromise proposal, then in turn that convention would have been brought back for ratification by our Senate and by the other parties to the Convention.

And if you have, say, two-thirds of the nations of the world—that would be two-thirds of 82 nations—agreeing that there had been a change in the international law, I think you would have a reasonable chance of getting the International Court of Justice to hold that that had accomplished a change.

Mr. HAYS. Thank you very much. Now I have one other question. This may be—it may appear to be a bit fanciful—but it relates to the common-law reference to the ownership of property.

There was an old statement that the owner of a part of the land owned to the center of the earth and to the top of the sky. Going down he knew he could own no farther than 4,000 miles, half the diameter of the earth. And when the phrase originated "to the top of the sky," no one had any idea, I presume, that the sky meant farther than a few miles.

But that, did stand for centuries at least—the rule. It is conceivable since space broadens the farther you go that a fellow, if he did own to the top of the sky, would own a planet out there; if that were theoretically accepted.

Mr. BECKER. He would have to share it with an awful lot of people because the earth is rotating. And he might own it for a fraction of a second while the earth turned around and his plot happened to be beneath the planet.

But a great number of other people in a ring around the earth would have an equal claim of right.

Mr. Hays. I am glad I asked it, because that disposes of my question. But wouldn't that be equally true when you apply it to sovereignty?

The only way we could assert sovereignty in outer space, projecting our earth area into space, is by exploration and discovery; isn't that true?

Mr. BECKER. Well, there seem to be two parts to that question. Let me turn to the first part.

Sovereignty in that type of a context might be defined as the "power to exclude." So that even though you were moving underneath and a constantly changing spot in space, because of your sovereignty, even temporary, over there, you had a right to exclude at least for the period that it was over your particular sovereign territory.

I might add that exactly what constitutes exploration or appropriation of space has not finally been determined. I am not a scientist, but I do understand that it might be technically feasible to put a satellite in orbit which bore such a relationship to the rotation of the earth, which in respect to a spot on the earth's surface would remain

immovable, and, therefore, you might have an instance of where you would have a Washington satellite, let us say, with men on board. It would all depend on the scientific possibility of that existing.

But I don't think we can exclude any of the possibilities in thinking of this problem.

Mr. HAYS. Professor Cooper wanted to comment on that.

Mr. COOPER. I simply want to amplify what has just been said. My scientific friends tell me—I explored this problem that has just been raised—that it would be possible to put a satellite in orbit over the Equator at 22,000 miles up. And if then it would be moving in the direction of the rotation of the earth, it would appear to be a fixed object.

There seems to be doubt as to whether or not a so-called fixed object satellite can be set up otherwise. This is thirdhand, but from two very able scientists with whom I discussed the matter.

I would like to amplify just one other problem that was raised.

If you put a rocket aimed into outer space with an initial velocity of approximately 25,000 miles an hour, it can, in theory, move outside the area of the earth's gravitation and get into what is really outer space. But to show you the difficulties of attempting to control any such parts of far-distant space for the purpose of making law effective, by the time that rocket got to the edge of the last gravitational pull, it would have taken about 6 hours to get there, and the earth would have moved one-quarter around, and you would be shooting into and controlling someone else's space if you tried to use this theory of projecting sovereignty indefinitely into space.

There are all kinds of problems.

And may I answer the chairman's question again: It is questions of such a nature which require a great deal more thought and study, and which I think such a space agency could well consider.

Mr. HAYS. Do I understand that as the law now stands, whatever law we can apply to this situation, it is legal to move across another sovereign state's area only a nonmilitary satellite?

Mr. BECKER. Well, there are two points. It has never been expressly recognized by this Government or, as far as I am aware by any Government, that another state has the legal right to put even a peaceful satellite over our territory.

The only thing that you can say is that you might infer an implied consent by the failure to protest the satellites that have been put up at this point.

I think it would be fair to say that if anybody attempted to put up a military satellite which had any offensive capabilities with respect to the United States, that this Government would take the position that that was not legally permitted.

Mr. HAYS. But as you said, we have the right reserved to all nations to defend ourselves. A defensive operation is different from an offensive operation in legal terms as well as military. But then on the other point I had understood there was some concession in the arrangements for the International Geophysical Year. There was that understanding; by concession.

Mr. BECKER. What I meant to say with respect to those arrangements is, first, they were not made on a governmental basis. We did not agree with other governments on it. It was made by the scientists, as citizens, international though they were. They were not govern-

ments. And, second, the only thing we have actually stated with respect to the satellites is the announcement of our plans to put them up and recognition of the fact, that there is an implied consent for the ones that have gone up to this point.

Mr. HAYS. Thank you, Mr. Chairman.

The CHAIRMAN. I would like to have both of you gentlemen put in the record first, if it is a one-man agency, the type of man you think should be appointed. His qualification. And if it is a commission form, the type of qualification of those who should comprise the commission.

If you have any thoughts now you can express them.

Mr. COOPER. As I read the bill, sir, at the present time, it provides for a technical director who is vested with most of the powers and a board that has advisory powers, the present bill seems to be a combination of those two thoughts.

Perhaps I have misread the bill.

The CHAIRMAN. The Director is the head. Under the NACA now, the Board is the real operating head. But this puts the Director at the head, with the advisory board advising him, but probably having some implied power more than advisory. This is because they have to be consulted before certain things are done.

That carries with it certain implications which you and I are aware of.

Mr. COOPER. As I take it, sir, the Director is not a member of the Board as it is now set up.

The CHAIRMAN. That is correct.

Mr. COOPER. A different situation might arise if the Chairman of the Board were also Director, would it not?

The CHAIRMAN. Well, I would think that any bill drawn up, if it were a commission form, for example, would probably provide for the operating director.

Mr. COOPER. I am sorry, sir. I stated it badly. As I understand it there is a clear distinction made in this bill between the Chairman of the Board and the Director.

The CHAIRMAN. Oh, yes, the Chairman of the Board is one of the 17 advisers appointed by the President; 8 of whom will be in Government; 9 outside; and the Chairman shall be one of the outside advisers designated by the President.

So, in reviewing your testimony, will you give us an idea of the type of a man whether he is director, administrator or commissioner—or in the case of a commission, the type of men, who should comprise the commission.

Mr. BECKER. It is my personal view that the individual appointed to either position should possess generally the qualifications requisite for appointment to a senior administrative position in the Government, such as a Cabinet member, departmental head, or member of a major agency such as the Atomic Energy Commission. While technical knowledge is desirable, the choice should depend basically upon demonstrated judgment and administrative capability, rather than specialized qualifications.

Mr. COOPER. A one-man agency should be a civilian of Cabinet caliber—experienced in administration, with significant scientific background, but with a broad point of view, a commission ought to include men with military, scientific, international affairs and legal backgrounds.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. Gentlemen, I want to thank you for the fine statements you both made to our committee. I would like to direct one question to Mr. Becker.

Assuming that our satellite procedure up to the present time violates no provisions of our laws that will cause us any trouble, what is going to happen, Mr. Becker, if we are unable to agree with the Soviet Union, and we have no codification of our law concerning this particular matter at the close of the Geophysical Year?

This bill, as you know, provides for research and problems of flight within and outside the earth's atmosphere.

What will be the policy of the State Department? What should be the policy of the State Department? And where do we proceed and how do we proceed at the close of this Geophysical Year?

What do you gentlemen say to that?

Mr. BECKER. Well, I think that the State Department, like the President, and like Ambassador Lodge, has already taken a position on that point. And that position is that we are urging the only other country that presently has a capability in the area with respect to which it arises—we are urging the Soviet Union to get together with us and agree that this shall be devoted to peaceful purposes.

Now, I would assume that when you came together to make such an agreement, you would at the same time define what were peaceful purposes and agreed-upon uses.

So you would automatically have, if we once get together to talk about this thing, a start from what we think is the focal point—trying to keep warlike things out of this brandnew area.

Mr. NATCHER. Mr. Becker, assuming no agreement is reached, we have no codification of our law concerning outer space and space generally; how are we going to proceed at the close of the present Geophysical Year?

What suggestions do you have to make?

Mr. BECKER. Well, Congressman Natcher, I think we would make that determination in a specific context. In other words, we would decide what we wanted to do, what we thought it was in the interest of the United States to do; and then we would take action accordingly. I don't like to answer that type of a question in a generality. It is a little too unspecific to deal with.

I would point out that we have already in one instance tackled that problem directly. A number of nations are presently engaged, again by the same type of vague agreement, in scientific work in Antarctica. There has been no agreement as to what to do after the International Geophysical Year. And just the other day you will have noted we sent out a note to the 11, I believe it is, nations which are either engaging in work there or otherwise have a direct interest in Antarctica. We are urging them to come together and sit down with us and work out some type of an administrative agreement to enable that work to be carried on in an orderly manner without having any conflict on sovereign rights or anything of that sort.

The suggestion we have made in that instance is that we reserve all our rights for the duration of that particular agreement. No activities that anybody may engage in that area will give them any additional rights.

There is one example where we have tackled that problem directly.

Mr. NATCHER. Professor Cooper?

Mr. COOPER. Being here as a private citizen, I would not for a moment indicate what I thought the Government's position should be. I will say this, however, that if I were a member of this space agency, one of the first things that I would do would be to say that this is the primary problem to be studied immediately.

Mr. NATCHER. Thank you, Mr. Chairman.

Mr HAYS Mr. Sisk.

Mr. SISK. I am sorry I missed the early part of your statements. I have been attempting to read your statement here, Professor Cooper.

Before we could put what I will term "communication satellites in space," under the several proposals we have had before us, and, where you space, say, three satellites in an orbit for mass television or other types of communication, then this whole legal question is probably going to have to be—well, not necessarily solved—but at least some type of international agreement will have to be reached before we could, with freedom, proceed to that type of operation.

Is that your understanding?

Mr. BECKER. That is not my understanding, Congressman Sisk.

There are a number of areas in which various nations have taken action, even though their respective legal rights were by no means settled.

In Antarctica various nations have made claims of sovereignty in areas where we have engaged in activities which in our view gave us rights. We have continued to take action in Antarctica, even though we have not conceded their right, nor have they conceded anything with respect to our rights.

It is a case where we have gone ahead and acted, even though the legal situation was not at all clear. That has been going on for 20 years without any difficulty.

Mr. COOPER. If I may amplify a little.

This may be one of the very few points on which Mr. Becker and I may not be entirely in accord. I am not as young as I once was. And I find I get more conservative each year that goes by.

It seems to me, sir, that if there is no understanding—and this is exactly the point that has been raised—if there is not understanding as to the legal status of outer space by the time the Geophysical Year ends, you may have a fruitful possibility of international misunderstanding when new types of satellites are launched.

Mr. SISK. The point I wanted to try to clarify in my own mind—and I think it is all-important with reference to the proposed new space agency—is whether we can move into even peaceful uses of this area—weather observation, communications, and so on? Are we going to be held up possibly? I don't know how fast we are going to move in this area, but with proposals we have before us, we could move rapidly into it. Are we to be held up by a matter of international law or international agreement?

I note your statement, your first paragraph on page 6 there with reference to the fixing of territorial space. And this struck me particularly. Where you say:

> Included in this category are the ideas that no agreement should be made and each state may claim territorial rights up to as high as it may exercise sufficient command to make its law effective.

And I agree with this:

> The world will then return to the theory that sovereignty depends on power alone—a disastrous outlook for the future.

If we proceed on that basis, then to me justice and equity in the world will have ceased to exist. It will become simply a matter of power and power alone, and probably will finally be dominated by a single power.

As I understand it, there is some disagreement—I am not trying to create a conflict between you gentlemen—as to how far we may proceed in these peaceful pursuits until there is some type of understanding by nations of the world in the use of this area.

Mr. BECKER. Congressman, I am not prepared to concede that the nations of the world as a whole have a veto power upon our right to engage in activities in space. There are a great number of nations in the world today—there were 82 attending this Conference—many of them are very new nations; many of them have very little experience in this field; many of them might well take the attitude if we attempted or recognized that they had a veto power that maybe the best thing for us to do is to take our satellites and go home.

I do not want to recognize that principle.

Mr. SISK. Then, I would assume that you would take the position that neither would we, as a sovereign power, have the right of veto over any other nation to engage in like pursuits.

Mr. BECKER. I would determine that question, and that is the way in which the Department would determine it, in a specific context.

What did we want to do? Did we think we had the right to do it under the circumstances then existing, whether or not there was an agreement.

What does another nation wish to do in that area? Do we regard that, under the circumstances then existing, as contrary to the interests of the United States. If we do there are a number of things that we could do.

Mr. SISK. Professor Cooper.

Mr. COOPER. You have put your finger on the most difficult problem that I think exists in this whole area. The very basis of the status of territorial sovereignty is that the sovereign state has a complete veto power, if you chose to use the word "veto," on what foreign activities take place in that area.

As a matter of fact, if you will note when I described the background of the Paris Convention, I called attention to the fact that the United States delegates stated the primary principle which was accepted as the basis of the Paris Convention, namely, the full and absolute sovereignty of each state over the air above its territories including territorial waters, carring with it the right—not power—the right of exclusion of foreign aircraft.

Therefore, if sovereignty exists indefinitely upward into space, then by virtue of such sovereignty, each state has a complete veto as to the use of that space.

As high as your territory goes, to that height, in the absence of agreement, you have complete right of control. As Chief Justice Marshall said—

> All exceptions to the full and complete power of a nation within its own territory must be traced to the consent of the nation itself.

I would concur with Mr. Becker in that what he has said may be the practical answer. But so far as my own judgment as a lawyer is concerned, if territorial space extends indefinitely upward, then a technical right of veto exists in any state flown over to deny even civil and peaceful uses of that space.

May I give you an example, sir?

The United States in negotiating rights of foreign aircraft to enter the United States permits one foreign airline to enter, denies another; it is not obligated to say why; for the reason that it goes back to what Vattel first carefully set out in the middle of the 18th century, namely, that sovereignty carries with it the complete right to control transport. And satellites, and missiles, are just another form of transport.

They are movement.

And if that movement is a foreign movement, you have no obligation of any kind to allow that foreign movement to enter your territory.

Therefore, I repeat what I said a little while ago: If I were a member of this space agency when it is set up, the problem that you have just stated, and which has been discussed before, would be the very first thing that I would be concerned with:

Is there any direct or indirect agreement as to our right to use space above the airspace.

Mr. FELDMAN. Would you include in the proposal before this committee a provision which would enable the space agency to undertake such a consideration and study?

Mr. COOPER. I would say, sir, that I would think that would be unfortunate. I think its powers should be very general; certainly you do not want to impinge on the long-established powers of other agencies of the Government, the State Department, the Civil Aeronautics Board, all of which deal with questions of policy as to transport. What I tried to make clear, Mr. Feldman, was that I hoped the agency would not be precluded from investigating these problems, which then might be included in recommendations to the operating agencies who would be primarily responsible for international negotiations, or something of that kind.

Mr. SISK. Mr. Becker wanted to comment on that.

Mr. BECKER. I was saying that this is an area in which we have got to do a great deal of work and study.

For example, the statement was made about the right implied from sovereignty of absolute control over transport. Is a satellite a transport?

Mr. SISK. Well, could I ask another question right there? This is something that seemingly could immediately confront us.

Maybe you do not want to comment on this. If you do not, you are perfectly free to state that you do not.

Assuming that tomorrow a Russian satellite, came down, and they were able to bring it down in exactly the area they wanted and could bring it down whole. Suppose it landed within the continental United States and it had significant military information or was of significance from a military aspect. What are you prepared to do about it from the standpoint of the State Department and our Government, now? What would we do?

Mr BECKER. That would be determined by the policy people in the State Department. I am just their lawyer.

Mr. SISK. I appreciate that. But aren't we very shortly, if we progress, going to be faced with that? And what we are going to say?

According to Professor Cooper's statement about airlines, we control whether or not Russia can send in an airline, or Sweden, or Norway, or whatever country. If a Russian satellite lands in this country, what will we do about it?

Mr. BECKER. Congressman, I think you have missed one aspect of the discussion that I raised earlier.

Mr. SISK. I am sorry if I did.

Mr. BECKER. I have already pointed out that this Government has taken affirmative action to get some agreement with respect to what shall be done about satellites. And it is not the fault of this Government that we are not moving forward and talking about the type of questions you have in mind.

I don't think it would be profitable for this Government, with its present knowledge of the facts with respect of outer space, to try unilaterally to develop a code of law with respect to outer space. Because that type of thing, when you get down to the last analysis in international law, international law is what sovereign states agree upon.

So we are taking initiative in the area.

Thus far we haven't had any indication that others were prepared to sit down and talk with us on that subject.

Mr. SISK. I can understand that. I agree with you, Mr. Becker. It is not something we can do unilaterally. The thing I was concerned with was just how far we have progressed. Apparently we have not progressed at all.

Mr. BECKER. I think the basic reason we haven't tried to get multilateral agreement on the types of questions that we have here is that there is a lot more study that we can make into the facts here before we are prepared to give an answer. Because, remember at all times that there are two aspects of this.

The one is this, what action is or could be taken by other states, and at the same time we have to think of what action is or can be taken by the United States.

Mr. SISK. Certainly. We can turn the situation around and assume that one of our satellites landed in Russia; then what would our position be?

Mr. BECKER. That is correct.

Mr. SISK. Mr. McDonough.

Mr. McDONOUGH. Mr. Becker and Professor Cooper, I appreciate your statements. You have enlightened us a great deal on a very difficult problem.

Insofar as the present satellites in orbit are concerned, the United States and Russia are the only two nations that have been capable of releasing them. Both countries released them during the Geophysical Year, which I understand was mutually agreed upon between those nations participating, that there would be no objection to the release of satellites into outer space during that year.

Mr. BECKER. There was no intergovernmental agreement.

Mr. McDONOUGH. Not intergovernmental; no.

Mr. BECKER. There was agreement among the scientists concerned with it. The governments did make affirmative statements they

planned to do this. And there was no protest by any government with respect to that announcement.

Mr. McDONOUGH. So that the mutual understanding that we have now, if only on a scientific basis, is only for the Geophysical Year.

The problem in my mind is that when the Geophysical Year terminates, if Russia should then declare that any satellite passing over her territory would be an overt act, are we prepared—is the United States Government prepared—to combat that situation?

Mr. BECKER. Well, our present announced position is that we want to talk about the general problem. And that includes the devotion to peaceful purposes. That is where we start from. That discussion will involve questions of what can be done. And we haven't given up hope that we may make some progress in that regard.

Therefore, we are not going to take a position as to what we will do if the year ends before we have started those talks, until it is necessary to do so.

Mr. McDONOUGH. Now in determining a territorial area over a nation into outer space, wouldn't we first of all have to chart that area and determine position, such as we do on water, the longitude and latitude positions?

Do we have any such charting of that area now so we can determine position?

Mr. BECKER. I was just looking for a definition. There is an interesting definition of airspace in the United States Air Force Dictionary. Airspace is:

> Space in the air or space above a particular surface of the earth, especially such space considered to have a particular shape and extent for a particular purpose.

In other words, airspace is commonly defined by the outline of the geographical area below it. And it is considered to extend upward indefinitely.

Mr. McDONOUGH. In considering that, if the earth were merely revolving, that is one thing. We are not only revolving, but we are rotating The territorial boundary lines of a state on the earth in the revolutions of the earth would be an instant area. We are traveling what?—1,100 miles by revolution, and some 66,000 miles an hour by rotation

So that these areas you are talking about in space, if they are accepted as territorial boundary lines, they would be instant areas, wouldn't they?

Mr BECKER. When you start talking on this subject with scientists, you sometimes get surprises. I was talking with a scientist on the general subject one day and talked about air space. We have the concept that the air above the United States is owned by the United States. That is not a fact. It is well known that weather is moving the air in general from west to east. So that the air we have in our air space above us today, a day or so ago may have been in Russia or may have been in Japan.

Mr. McDONOUGH. The physical air.

Mr. BECKER. I meant to say the fact that there is movement or that the airspace above you may have different molecules in it is not a new problem. And even though we have absolute sovereignty, let us say, over our airspace, if we were to extract all of the oxygen from

the air as it left our east coast, I think other nations might have something to say about it, regardless of our absolute sovereignty.

And so we have managed to work out a system of sovereignty of airspace, notwithstanding the scientific facts that scientists deal with every day.

I would suggest in our problems on outer space, even though they seem new, we need a great deal of study of what are the facts, where are you in relation to various areas when you are actually up there, before we make any decision as to what should be sovereign rights there.

Mr. McDONOUGH. To determine where you are, wouldn't you have to chart the area? Wouldn't you have to have a known specific point determined by geometric lines or bands of area around the universe, taking the sun as the center of the galaxy. We are part of a planetary system. We are one of the satellites of the sun. There must be some boundary line on which we could chart our position, and then as a nation determine if our territorial rights are limited in outerspace to that area—or geographic area on earth.

Any invasion to that area by another nation would have to be determined as to what time that invasion was; because the position is different both in revolution and in rotation.

Mr. Cooper, what is your opinion of that?

Mr. COOPER. My own view, sir, is that the air, as air, has practically nothing to do with it.

I think we are talking about space That dispute first arose historically about 1906 between two professors, one talking about sovereignty of the air, and one talking about the sovereignty of the airspace. It has been proved that it is the sovereignty of the airspace involved.

I think we are going to end up with some kind of agreement that the space X distance above the surface of any state is part of the territory of that state.

I would like to see some general attempt at a fairly early date to reach that kind of a conclusion. I may be entirely impractical. Maybe it is better to take it on a case-by-case basis and proceed as the Government of the United States has alone discussed at this time—the peaceful use of outer space—without saying who is sovereign in the areas to be used.

In other words, the present attempt, as I understand Mr. Becker, has been that there should be an agreement on outer space—and I would call your attention, sir, to the fact that neither the President nor the Secretary of State in any of the communications—nor Mr. Lodge—defined what they meant by outer space.

They simply said there should be peaceful use of outer space. That was the case-by-case effort to preserve the right to use peacefully for all concerned an area without determining the sovereignty of the area.

I think sooner or later the United States has got to decide how high what I call its biggest boundary is.

In other words, are we 50 miles away from international territory above us; are we a hundred miles; or are we a thousand miles away?

It is a fact that sooner or later we have got to determine. I think, however, the crucial thing at the present time is that there should be some understanding that we may continue the peaceful use for scien-

tific purposes of areas above and beyond the airspace in the strictest idea of airspace where there is enough air to support an aircraft.

And that is a case-by-case problem.

Mr. McDONOUGH. At the present time we do have international law or at least international understanding as to what area a foreign aircraft can enter over the territorial United States. What is the maximum height of that?

Mr. BECKER. There is no maximum stated.

Mr. McDONOUGH. There is none?

Mr. BECKER. There is none; no, sir.

Let me add one word on that problem of sovereignty in space.

I do not think we should be in a hurry to delimit or restrict the sovereignty of the United States unless we know that we are on the right road.

Now, the problems that people have with respect to space vehicles and satellites does not relate to the question of sovereignty basically; it relates to the question of what is the effect of these objects upon me or we and our interests. Now, our approach is to put aside for the moment the relatively theoretical question of sovereignty, because we might make a mistake.

And then to concentrate on seeing if we can get some agreement so that these objects will not be used in a manner that is contrary to our interest.

It is only after we have a great deal more knowledge that I feel we want to make a final decision that the boundary of the United States goes this far and no farther. Because once that decision is made, it is a permanent decision.

Mr McDONOUGH. Well, isn't there some indication of the attitude of Russia, especially in the Arctic, here in this recent attempt on their part to say that we were invading their area?

Mr. BECKER. I did not see any claim of invasion.

Mr. McDONOUGH. Well, they claimed that the SAC bombers were traveling over their areas.

Mr. BECKER. They said we were approaching their border. I do not recall that they claimed we infringed their territory.

Mr. McDONOUGH. Then, what is this most recent dispute in the Arctic; the one you just cited a few minutes ago that for some 20 years we have been operating within areas that are undefinable as far as territorial rights are concerned in the Arctic.

Mr. BECKER. That was the Antarctic.

Mr. McDONOUGH. The Antarctic?

Mr. BECKER. Yes.

Mr. McDONOUGH. In other words, if we do not take a position soon, restricted or otherwise, and if Russia should take a position that all outer space is their territory—then we are challenged, and we will have to take a position; isn't that right?

Mr. BECKER. It makes no difference whatsoever, sir. We faced that problem with respect to the Antarctic. Because people have been urging us for years and years and years—they have been urging the United States to assert a claim in the Antarctic.

And we have pointed out time and time again that our rights are not dependent upon making a claim.

In international law, when you have rights, you do not have to make claims of sovereignty in order to be entitled to the benefits that

those rights confer upon you. And there may be times when it is politically unwise to make a claim.

It is much better to adjust the thing in a practical manner. That is the general approach we have adopted with respect to Antarctica.

It has not worked badly, really.

Mr. McDonough. And has that been accepted by Russia?

Mr. Becker. I have not seen whether we have an answer to the note as yet.

It only went out a few days ago. And it is a relatively major proposal.

Mr. McDonough. That is all, Mr. Chairman. Thank you.

Mr. Hays. Mr. Fulton.

Mr. Fulton. May I compliment Mr. Becker on his foresightedness in last year starting into the study of the law of outer space as the leagal adviser and counsel of the Department of State.

Mr. Becker. Thank you.

Mr. Fulton. I think he has been forward looking and has certainly been giving this matter some thought, even prior to action by Congress.

Likewise, I would like to compliment Professor Cooper on his fine work over the years. These matters that have not had public attention and seemed of no great importance are often a heavy burden to carry.

My first question is basic—I am a member of the House Foreign Affairs Committee: Is space policy foreign policy, as far as the United States Government is concerned?

Will you put that in the record later?

The second thing is this:

Under our United States Constitution we are a group of 48 States, each with a State sovereignty over its territory. And then the question comes up: Is this a Federal jurisdiction or a 48-State jurisdiction, with each State having sovereignty over its own territory?

I would rather move quickly. So you may revise your remarks when you review the record.

(Mr. Becker's response will be found on p. 1307.)

Mr. Becker. I haven't considered that domestic aspect. But my offhand answer is that Congress has settled that question by the Civil Aeronautics Act and related acts in which the Federal Government regulates air movement above the States, because it is generally interstate.

I think they even regulate intrastate movement through the CAB.

Mr. Fulton. Well, of course, Congress is given the power to make all laws which shall be necessary and proper for carrying into execution the powers of the United States and of the Constitution.

That would be in article I, section 8.

Now, would it come under that Constitutionwise; or are we just proceeding by assuming the authority?

Mr. Becker. I do not quite understand that question, Mr. Fulton.

Mr. Fulton. You say Congress has already done it as far as aeronautical rules and regulations are concerned. So, I am saying: Is it under the general powers of Congress given under article I, section 8, where we are allowed to make all the laws which shall be necessary and proper for carrying into execution the general powers?

Mr. Becker. No, I believe the various air acts are under the interstate commerce power.

Mr. Fulton. Professor Cooper?

Mr. COOPER. If your staff will find the history of the Air Commerce Act of 1926, that reflects exactly a long series of debates which occurred 5 or 6 years before that time as to whether, in order for the Federal Government to regulate flight, a Constitutional amendment would be necessary or whether it could be done under the various clauses.

There was a general agreement finally reached, which the Congress apparently acted on in the adoption of the Air Commerce Act of 1926, that flight could be a subject of Federal regulation.

I think you will find that one report of the American Bar Association Committee in the early days went so far as to raise exactly the question that you had, the question of whether or not a Constitutional amendment was not needed.

Mr. FULTON. Well, my point is this, really: Whether we have to put it under something like the commerce laws, when obviously there is no commerce in outer space or whether we put it under article I, section 8, which is the general powers given to Congress to implement the Constitution.

We have the right to make all the laws. And, likewise, we have the right to make laws and regulations that will carry out any other powers in the general powers vested by the Constitution in the Government of the United States or any department or officer.

Mr. BECKER. I would not be inclined so quickly to put aside the commerce

There is the potentiality of commerce and the potentiality of foreign commerce.

I think you would have some sound ground for acting there.

Mr. COOPER. I concur with Mr. Becker.

I think such legislation as we have before you could be justified under both clauses.

Mr. FULTON. I see.

Now, then, you would take an air vehicle with an earth-to-earth destination as surely being under the previous decision. But the query is: Suppose you had an outer space missile which just went off like Columbus in 1492?

Mr. BECKER. I think the constitutional concepts there will have to keep up with the facts.

Mr. COOPER. Plus the potential of the United States as a fundamental matter.

Mr. FULTON. I live in Pennsylvania. And we remember the 16th amendment. That says Congress may—well, take the 10th amendment—the powers that are not delegated to the United States by the Constitution or prohibited by it to the States are reserved to the States respectively.

Now, the question comes up: I am in Pittsburgh, Pa., and our local government decides we are going to shoot a rocket to celebrate our 200th bicentennial there in outer space.

And you people in the Federal Government come along and say you are not allowed to. I say "All right." I am a private citizen there, and I say I am going to. So the question comes up: Am I as a private citizen allowed to enter into outer space without an exit visa or without a permit or paying a license fee to put a rocket up.

Or could I as a municipal government, as part of the government of Pennsylvania, go ahead and do it?

Or are you going to limit that solely to the Federal Government and keep everybody else out of it?

Mr. BECKER. Well, I suppose the easy answer to that question is—well, I may say that with respect to matters of domestic law I trust you do not hear me as a witness on behalf of the State Department; it is merely an interesting discussion as far as I am concerned.

But I suppose we won't have to——

Mr. FULTON. Or, secondly, let me ask you this: Will there be free enterprise in outer space? Can I send up something that says "Fulton's Vitamins"?

Mr. BECKER. The quick answer to that right now is that it would be so expensive to put these objects up that the problem is not going to arise immediately in a practical context.

Mr. FULTON. Yes.

The theory that we put in outer space in a philosophy will probably, through the work of this committee, have a governing impact just the way these various things cited by Professor Cooper have had previously.

Mr. BECKER. I do not mean to say that there aren't all sorts of questions we are going to have to go into here.

But I think you are demonstrating that we have got a lot of studying to do.

Mr. FULTON. May I say to Professor Cooper: Let's go back into history——

Mr. COOPER. May I interrupt you?

Mr. FULTON. Yes.

Mr. COOPER. It seems to me that we might take a look at the final decision in the Tidelands case in which it was held—and I thought it was bad law, but I do not have the last word—in which it was held that Federal jurisdiction alone existed because the doctrine that the territorial sea is part of the territory of the United States did not become part of international law and the law of the United States until after the Constitution was adopted; and, therefore, the territorial sea was after-acquired Federal territory and did not become part of the adjacent States.

Perhaps we may reach a problem where any extension upward of space not now used may be held hereafter by some court as after-acquired territory so far as the United States is concerned.

Mr. FULTON. Previously, we discussed the height to which property that is owned by a citizen of the United States goes. If property lines are parallel lines on each side of the property intersecting each property line, we would then get either a square or at least some sort of a section that went out through space continuously.

But if you say that isn't the case, then you are going to have to say that the property lines are really the extension of a cord that starts on the earth's surface, and on each side of the property goes out through where the property line intersects the circumference of the earth, or about there, and then goes out into space.

Now, on the first assumption, I would say to Professor Cooper, the peculiar thing is that if I have a hundred feet of property on the earth and go up a thousand miles above the earth, and I am going to try to determine what property I have up there, the circumference of the earth at a thousand miles would have gone 2π. So its circumference instead of being 24,833 miles would be 31,416 miles.

Likewise my 100-foot square plot of property 1,000 miles out in space would have a gap of 50 feet separating it from the plot of my neighbor if his were of similar size. If our two plots were larger, the gap would be larger.

Mr. COOPER. I agree with you if you accept the concept that private property extends indefinitely upwards in space; I think that was destroyed in the United States by the Causby decision in the Supreme Court.

Mr. FULTON. Yes.

But then the question is: Who owns the property as soon as I get up an appreciable distance between me and the man who owns property next to me in the United States? Who owns it?

Mr. COOPER I think the reasoning would be that you move from the line through the center of the earth, through the edge of your property upward in space; so, your area would not be a box.

Your area is, in my judgment, defined by the two lines that move from the center of the earth through your boundaries.

The only question is as to where the top of the atmosphere is.

Mr. FULTON. So, really, we get out into outer space where we own many, many thousands of miles—hundreds of thousands of miles—of space, and we are then separated between each other by a distance, for example Russia and the United States, that we do not even know.

We cannot even tell within a third of a mile how far New York is from Moscow, for example.

Mr. COOPER. I thought the inaccuracy was even larger than that.

Mr. FULTON. There is even a disagreement between the Russians and ourselves on the inaccuracy.

Mr. COOPER. I do not believe in this case—or I do not think the problem really affects these considerations at all.

Mr. FELDMAN. Is there any analogy, getting back to your original question about your rights as a private citizen to shoot a rocket into the air or into space—is there any analogy in the licensing features in the aeronautics law which requires anybody flying to have a license before he can fly?

Secondly, isn't there also an analogy due to the fact that aircraft are constantly flying over property. And the fact that they continue to fly in that same area or continue to fly over that property might give them some adverse right.

But nobody does anything about it anyway.

Mr. COOPER. By your first question, you pinpointed one of my real problems about the present status of the law in the United States.

As I pointed out in the paper I filed with you, a rocket in my judgment is not an aircraft subject to regulation under any of our present statutes and regulations on account of the definitions involved.

Mr. FULTON. I must disagree with you.

Mr. COOPER. I am giving you my professional judgment for what it may be worth. We have not attempted to regulate anything but aircraft.

Mr. FULTON. Under article X, section 3 of the Constitution, the Congress shall have the power to dispose of and make all needful rules and regulations respecting the territory or other property belonging to the United States.

Certainly that rocket belongs to the United States.

Mr. COOPER. I say up to now there has not been, in my judgment, adequate regulation of rocket flight.

Mr. FULTON. But there is the authority in the United States to regulate it?

Mr. COOPER. The authority certainly exists. There is no question about that at all

Mr. FULTON. No matter where?

Mr. COOPER. I agree thoroughly if it is an American rocket.

Mr. FELDMAN. We do have the right to regulate?

Mr. COOPER. No question about that at all.

Mr. FULTON. If you put a person in it, we have the right under the 16th amendment; because we can tax it up there if we want to, can't we?

So that maybe Congress is moving into a field where we have the right to tax in outer space, do we not? Is that right?

Mr. COOPER. That is one that I have never thought of before.

Mr. FELDMAN. How would you collect the taxes?

Mr. COOPER. To finish answering Mr. Fulton's question. I think the adjudicated cases are now pretty clear that there is no prohibition against normal flight in areas that do not injure the use of the subjacent property; and that the mere continued flight to and fro does not at the same time give the man flying any property rights in the lands below.

Mr. FULTON. Suppose we put a Navy man in one of these space ships and send him into outer space; does it pay his income tax under the 16th amendment when he is out in outer space?

Mr. COOPER. When I was a naval officer they hadn't invented the income tax. I would not know.

Mr. FULTON. The 16th amendment specifically says that Congress shall have the power to put an income tax and collect taxes on incomes from whatever source derived.

So that means outer space too.

So, if the man is paid for working in outer space, we tax him, don't we?

Mr. BECKER. Paid by whom?

It seems to me—I am not going to discuss the tax laws, but you certainly collect income taxes regardless of whether or not a man spends the year in China or Europe.

It seems to me that——

Mr. FULTON. Well, here is a new frontier. Do we collect them in outer space?

Suppose I shoot a satellite into outer space and still own it, can I collect income depletion on it or is it lost?

Mr. BECKER. The answer to that is: If outer space is within the sovereignty of the United States, there isn't any question of it.

If it is not within the sovereignty of the United States, it depends upon your right to tax citizens when they are outside the territory of the United States.

Mr. FULTON. Now, our bill, as set up, has a civilian agency.

And we limit it. We give it full power except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations. That means we do not have one agency that looks after the whole space policy of the United States.

At this point I favor a space agency which implements a national space policy, both military and civilian, as outlined and set up by the President and, of course, under regulations and laws of Congress.

Do you go that far? Would you have just a space agency that is civilian alone, and then have another military space agency such as the Advanced Research Projects Agency—ARPA—under the Defense Department? Or would you combine the two?

Would you have an overall space policy agency?

And I have one question in conclusion:

In our philosophy of approaching outer space, should we approach it the way countries approached the 15th and 16th centuries? Should we take Grotius' approach of the freedom of the seas, or should we take John Seldon's approach for Britain in 1635 when he said that Britain must have dominion of the seas?

Or should we take Cabot Lodge's approach and put it in the United States? Or should we take the method that was proposed and acted upon in 1899 on the First Hague Conference, in 1907 on the Second Hague Conference, a conference of all the nations of the world, to try to work out a policy for outer space just as we did on the International Court of Justice?

You see, mine is the latter.

I would say don't put it in power politics through the UN, but start it with that kind of a conference called through possibly NATO, and put it at the summit in the next conference, with preparations through NATO.

Mr. COOPER. Can I answer that question purely as a private citizen and scholar?

Mr. FULTON. I would like to have you do that; yes, sir.

Mr. COOPER. I have always been impressed with the great admiralty decisions of the early part of the 19th century, which put the doctrine of freedom of the seas on the basis that the seas were a highway which should be maintained open for all states.

Grotius argued the doctrine of the freedom of the seas largely because they could not be possessed or controlled. He stated that there was no power to control the seas.

On the other hand, when the great admiralty decisions in the British and American courts came out at the end of the 18th century and the beginning of the 19th century, it was laid down that the doctrine of the freedom of the seas was primarily a problem of maintaining for the use of the peoples of the world a common highway which should not be impeded or seized.

I feel exactly the same thing, if I may say so, as to outer space. I think its future is part of a great highway for the peaceful use by the peoples of the world.

Mr. FULTON. But you do not think that if we adopt the power-to-control theory that we are then in a race in outer space—higher and faster with military weapons—and we will finally end up as England and Spain did, with the Spanish Armada; that we finally will come to the point where we have got to have a showdown on it for the power to control?

Should we go on that basis?

Mr. COOPER. I thoroughly dislike the theory that sovereignty is based on power. I asked a distinguished lawyer once who had

served on the World Court whether sovereignty was the right to control or the power to control.

I never did get a very concrete answer, but to me sovereignty is the right of a state to control a particular area within boundaries which the international community has admitted exists.

Now, I think that was approximately the basis on which Dr. Huber decided in the island of Palmas arbitration as to what constituted territorial sovereignty.

Mr. FULTON. That is my last question.

May I ask you if you would put a summary of your War College lecture in 1948 in the record?

Mr. COOPER. It is no longer classified. Yes, I would put that in.

Mr. FULTON. Like your materials on missiles and satellites policy of 1958 and the legal problems of upper space?

Mr. COOPER. I have given copies to Mr. Feldman.

Mr. FULTON. Likewise from Mr. Becker a summary of your testimony before the Foreign Affairs Committee on this same subject, if you would.

And then I would like in the record, too, the Paris Convention, the Chicago Convention, either summaries or outlines of them, as well as the annexes, so we can have them for reference material, as well as any documents these gentlemen have referred to of a legal nature.

Mr. COOPER. The United States published in the early part of 1940 or thereabouts an official copy of the Paris Convention with the annexes in all three languages. So far as the annexes to the Chicago Convention are concerned, they are very voluminous. I regret that personally I am not in position to supply the desired material.

Mr. FULTON. I said summaries.

Mr. HAYS. If the gentleman will amend his request to provide that the summaries are to be checked with Mr Feldman?

Mr. FULTON. That is right.

Mr. HAYS. So there will be some screening.

Mr. FULTON. That is right.

And any pertinent provisions you referred to, that we put those in the exact words particularly.

Mr. HAYS. Without objection, they will be made part of the record.

(Material referred to begins on p. 1310.)

Mr. HAYS. Mr. Keating.

Mr. KEATING. Messrs. Becker and Cooper, this question is addressed to both of you.

I gain the impression despite your statement that you were in substantial agreement—I gained the impression that you, Mr. Becker, would prefer to await the gathering of more significant and reliable physical data on outer space before we begin to make new law and suggest a case-by-case approach.

On the other hand, my impression of Professor Cooper's position is that he considers the political implications of the situation imminent and grave enough to act now or in the immediate future before dangerous disputes arise.

Would that be a fair analysis of the divergence in your thinking on this point?

Mr. BECKER. I do not know exactly what we should do now, because the implication I do not entirely agree with is that we are not acting now.

We, through the President, through the Secretary of State, and through Ambassador Lodge, have taken some significant action now. It began as early as January of 1957, I believe, in the United Nations.

And we have called upon the other power that has a capability in this area to agree with us that it will be limited to peaceful uses.

And, as I have said before, when you discuss this basic question, you are bound to discuss what those uses are and what is permissible and what is not. So that we are acting now.

But the thing that I do not want to do and that I think the Department does not want to do is to sit down and write an *a priori* code of laws with respect to space when no man has ever been there. And I do not think that we have enough knowledge to say exactly what the conditions will be that we want to legislate about.

But I do not want the impression taken that we are simply saying that nothing should be done now.

Mr. KEATING. Well, could I ask, Professor Cooper, what do you have in mind that could be done now which is over and beyond what is being done?

Mr. COOPER. Mr. Keating, I feel and have felt very strongly that if negotiations could go forward such as those which Mr. Becker has referred to, that when you reach new international agreement as to the peaceful use of outer space, you will have reached a practical answer to the question of the height of territorial space, because I think they are part and parcel of the same thing.

My major concern is this: I hope the decision as to the territorial upper space boundary of the United States will not be too long delayed. I fully agree that if negotiations which were taken up could be actively handled, that within those negotiations there would necessarily follow a determination as to what extent a state could or could not impede future civil flight—provided at the same time that there were a determination that whether it was territorial space or not, military flight above another state could not be undertaken.

I think on the basis of that very simple formula that the President proposed and that Mr. Lodge followed in the United Nations and which was discussed in the Disarmament Commission in London—I think on that very simple formula of the peaceful use of outer space, you open the gate to solving the major problems.

My concern is that there is no solution now.

Mr. FELDMAN. Could you summarize what has just been said this way:

That one of the aims of the President's proposal and the legislation before us is the exploration of space, and your suggestion is that concomitant with that, we must also explore the law of space?

Mr COOPER. Yes, sir.

So that we may be sure that this commission or this board or what ever it is, this agency, in seeking to explore outer space for peaceful purposes does not collide with unsettled problems which may cause serious international dispute.

That is my major concern.

Mr. KEATING. Do you think there would be merit, despite the strong statements which the President has made declaring that outer space should be used only for peaceful purposes—would there not be merit also in a congressional resolution stating that to be the sense of the Congress as expressing the will of the American people?

Mr. COOPER. Mr. Keating, I am not sufficiently knowledgeable of the difference between the statute and the resolution, or to what extent they are needed to assist or aid any executive pronouncement, to say.

I think that should come—I can only say, my personal view has always been that anything that can be done to assure peaceful use of outer space should be done.

As to the mechanics, I do not presume myself qualified to say.

Mr. KEATING. Probably, Mr. Becker, you might not want to express a view with regard to that?

Mr. BECKER. I would prefer not to at this time, Mr. Keating.

Mr. KEATING. I note on page 6 of your statement, Professor Cooper, that you say "Preferably that a new convention be adopted fixing the boundaries" and so on.

In other words, that is the course you think is the preferable one.

Do you think immediate steps should be taken to bring that about by international agreement?

Mr. COOPER. I feel about that exactly as I do about the position with reference to what has been termed a summit conference; that there should be adequate preparation before any such convention was ever called.

And I would call your attention to the fact—I do not know whether Mr. Becker knows it—that the State Department in 1943 and 1944 explored at great length with the major flying nations of the world problems that might arise at the Chicago Conference before they ever called the Conference.

In other words, sir, I feel the very objective that I have indicated as desirable might be destroyed by too precipitant calling of a diplomatic conference to consider undigested proposals.

I went through a similar experience in 1947 with a conference also at Geneva where we sought to clarify certain of the unwritten parts of the Chicago Convention as to commercial flights. And there it broke down because there had not been some general understanding in advance of what certain nations—what positions certain nations might take.

Mr. KEATING. Professor Cooper, you have gone over this bill, I think you said.

Mr. COOPER. I have, sir.

Mr. KEATING. Do you think that on the second page of it that the way it is drawn there is an overemphasis or too great emphasis placed on military control as has been indicated recently by some high authorities?

Mr. COOPER. That I have not studied.

I was studying particularly where the agency might have to deal with the problems with which I was concerned, namely, research into problems involved in peaceful flight.

The problem you have just raised I have never focused upon.

Mr. KEATING. Well, I was rather amazed to see a statement by a distinguished Member of the other body to the effect that this legislation as proposed placed too much authority in the military. I would think perhaps just the opposite was the fact and that we should give the military more of a voice in the consideration of policy questions than is incorporated in this legislation.

I am referring particularly to that sentence which says Congress declares that the activities shall be directed by a civilian agency except such as may be peculiar to or primarily associated with weapons systems, in which case the agency may act in cooperation with and on behalf of the Department of Defense.

Now, certainly the Department of Defense is the one which at present has done the extensive work in this field. And I would be happy to have your comment on that provision.

Mr. COOPER As I read this, as a lawyer, and only as a lawyer, and I have not studied it very materially, I took it that the court might well say that the activities referred to are the use of space and that normally the civilian agency should have general control of such activities except as they were military; and I would assume that in order to come within the exception, there would have to be a showing they were peculiarily or primarily associated with the use of governments

Mr. KEATING. That is my interpretation.

Mr. COOPER. That is the way I would construe that, that where a general power is granted subject to an exception, the person seeking to rely on the exception must indicate that he is entitled to the exception.

Mr. KEATING. That is right.

And the Defense Department, through several witnesses, has made very strong representation to us that this places too great a burden upon them and that they need to have a rewording in order to give them a greater voice in space exploration.

Mr. COOPER I know nothing about what decisions may have been made by the people who drafted the bill or by the President in recommending this But you have asked my view as a lawyer.

And, as a lawyer, my judgment would be that the primary responsibility is put upon the civilian agency, but there is reserved out of that those things which are essentially military And that, if I may say so, is not very different from the present situation as to flight in the airspace, as between the Civil Aeronautics Board and the Armed Forces

Mr. KEATING. Departing from your position as a lawyer for a moment to that of a citizen, isn't it your impression that that is the way it should be set up?

Mr. COOPER I think, sir, that this would be workable.

Mr. KEATING. Would you care to comment on that, Mr. Becker? Have you gone over that wording? What do you think of that wording?

Mr BECKER. I would really prefer not to comment, because I am appearing here as a Department witness.

Mr. KEATING All right.

I think any assertion that this bill, as drawn, places too great authority in the military is completely without foundation

Mr. FELDMAN. Would you yield for just a short point?

Mr KEATING. Yes, sir.

Mr. FELDMAN. I think when Dr Dryden was here he felt there might be some ambiguity in this particular point. The exception says:

> Except insofar as such activities may be peculiar to or primarily associated with weapons systems of military operations in which case the agency may act in cooperation with or on behalf of the Department of Defense.

Dr. Dryden felt the words "on behalf of" may have conveyed a wrong connotation.

Mr. COOPER. I would certainly agree that that might be clarified. I can understand cooperation, but I don't understand what is meant by "on behalf of."

Mr. KEATING. With these satellites orbiting around the earth and with the talk that we hear about rockets to the moon, and other kinds of vehicles in space, you would both agree, would you not, that we need additional laws to govern the problems not only of the rights and liabilities as between the nations, but as between nations and individuals?

In other words, that we must have some new laws to meet these new concepts?

Mr. BECKER. Insofar as these objects come into the airspace and have some effect upon individuals, I think we have an existing body of both domestic and international law that we could apply without having any specific new law.

That is to say, I do not think it is very different if a satellite falls on my house from an airplane falling on my house.

Probably the liability would be more absolute in the case of a satellite, because it is more analogous to shooting a bullet which may fall on anybody; in that area I think we have a body of law that, again, until we learn a little more of specific problems we will have to face, would be adequate for the present time.

If you are speaking of relationships between governments and individuals when the individuals are located in outer space, I suppose other than the laws of nationality, allegiance, and so on, and so forth, we might have to think out some additional law.

Mr. KEATING. But you think our domestic laws today are broad enough to cover problems that would come about through misguided missiles or collisions in outer space, if that is possible of conception, or the rights of a launching nation to a downed satellite which comes down in another country.

Mr. BECKER I have not studied the domestic law with that in mind.

I am not certain whether there should be a clarification of the civil aviation laws to insure that they would govern the flight of missiles and things of that sort. I have given some thought to the international aspects of it

And, as I see it, we have well-recognized international law governing airspace. And there is no question in my mind but that an infringement of the airspace by a satellite or missile would be identical with the infringement of the airspace by an airplane.

And under certain international law, we have very well-defined rights in that regard. We have the right to say "Stay out. We do not want you in there."

And we have the sovereign right to insist upon that. If others do not recognize that, then we have the sovereign right to confiscate or take such action as we deem necessary to protect ourselves.

Mr. COOPER. The entire problem, sir, in my judgment, goes back to my two basic concerns: That we must know the legal status of the area in which the movement takes place.

If it is airspace, if it is part of the territorial space of the United States, then the law of the United States will apply, whether it be

private wrongs or otherwise. If the area of the occurrence which gives rise to the right occurs outside of the territorial jurisdiction of the United States, then you have an entirely different problem.

And basically, as a man who has tried to study these questions for a long time, I feel it is highly important that we should not too long delay determining where the law of the United States, as law, is effective.

It is effective within its territory. I want to be sure where we find the territory of the United States.

The next thing is that you must determine the legal status of the instrumentality. That is a point I suggested in my paper. And you have real difficulties. While I agree with Mr. Becker, we can forbid on a general basis of international law the entrance of rockets and other things into our territory, nevertheless, the regulation of flights of rockets in our territorial space does not now exist.

We have a right to regulate them, but we have not done so.

Mr. BECKER. May I add a word, Mr. Keating?

Mr. KEATING. Certainly.

Mr. BECKER. The reason I answered the way I did is that as I understood your question it was a further law with respect to the relationship of the government and citizens and their rights and things of that sort.

And that is why I deliberately confined myself to the airspace; because when you get beyond that, you just don't have any citizens outside there. And my feeling would be: let's wait until they get out there, until we see what the legislation will do as to their activities out there.

Mr. KEATING. I have another committee meeting at 2 o'clock. But I do want to express to you, Professor Cooper, my personal gratitude for the assistance you have given me in some of my space activities.

Mr. HAYS. Mr. Ford.

Mr. FORD. As Professor Cooper indicated in his prepared statement, the Soviet Government has for many years asserted its airspace sovereignty.

From a practical point of view, we know what they have done when any aircraft have actually or allegedly violated their territory. In addition, isn't it true that before they landed any of their aircraft in the United States, they sought permission from the United States?

Mr. BECKER. That is correct. They would have to do so.

Mr. FORD. It is my recollection that within the last 3 or 4 months they landed one of their aircraft here, and prior to that had sought actual permission for such a landing.

Mr. BECKER. They have no scheduled routes coming into the United States. So, each flight, a separate arrangement is made.

In the exchange agreement that we recently concluded with the Soviet Union, there is a separate provision for the parties discussing the possibility of a scheduled route between Moscow and Washington. They would be obligated to do that.

Mr. FORD. In other words, whether they have approved officially at the Chicago Convention as a practical matter, they have abided by the intent of the Convention?

If we expanded the intent of the Chicago Convention to go beyond the intent at that time, then that is a precedent for us to control outer

space and is likewise a precedent for them to control outer space; is that correct?

Mr. BECKER. That is correct.

You say if we said that our sovereignty extended into space, that would be a unilateral determination and ultimately if enough nations said that it would become customary international law?

Mr. FORD. Yes.

And the Soviet, by practice, have set a precedent, if we followed the agreements under the Chicago Convention to go beyond the airspace that was used as the formula in those days?

Mr. BECKER. I do not quite understand that question, Mr. Ford.

Mr. FORD. Well, they in practice have agreed to the intent of the Chicago convention?

Mr. BECKER. That is correct.

Mr FORD. If the rest of the nations of the world used that formula hereafter, going beyond what airspace was meant to be in those days, haven't the Soviets found themselves in a precedent position that would more or less force them to carry it out in the future in the same way?

Mr. BECKER. They could take that position.

They could, of course, take the contrary position on the theory that it would be more in their advantage to deny that despite the fact that other nations had unilaterally determined otherwise.

Mr. FORD. If we take the position of the Chicago convention and extend it, and if there is an obvious military satellite circling the globe violating our territory, we have the right to destroy that weapon within our territory. Do we have the authority to destroy it just because it crossed our territory but might have gone outside our territory?

Mr. BECKER. Well, I think the specific right under article 51 of the United Nations Charter is to protect yourself—the right of individual and collective self-defense against armed attack.

It would be a question of military judgment as to whether or not that constituted that type of an infringement.

Now, something short of armed attack could endanger your security to an extent that you felt you were entitled to take affirmative action with respect to it. The situation has come up in numerous cases—I think we have 2 or 3 now pending before the International Court of Justice—of where an airplane overflying some of the Soviet bloc airspace through an error in navigation or for some other reason. When that occurs, we recognize that it was not by right of our part; and in a number of instances, where they have gotten the plane to go down, we have apologized, and the pilot has been sent back, and sometimes the plane sent back.

But we do not recognize, where it is an inadvertent invasion of airspace, the right offhand to shoot them down.

You get some difficult questions there. When you get into that area, you cannot give a categorical answer. Because, after all, it is a military judgment as to what is endangering you or what is not. And when you get a very fast plane, you sometimes cannot tell whether it is there with evil or good intent.

Mr. FORD. In other words, we have not taken the position that we must design our antisatellite equipment so that it will, of necessity,

destroy a military satellite, while it is in what we allege to be our own territory, the airspace that we contend is ours?

Mr. BECKER. We haven't taken any position on that specific point.

I think one of the things that one would have to consider in relation to any position you took would be:

Is it manned or unmanned?

Because there may be a difference between offhand shooting down a manned and controlled vehicle that can get down or that you can force down, as distinguished from one that is remote-controlled, or is merely mechanical, or electronic.

In the latter case you would have much less hesitation on taking affirmative action with respect to it.

Mr. FORD. They do not tell us whether it is manned or not.

Do we assume, then, that we have the right, regardless?

Mr. BECKER. That would be a military judgment of: Does this constitute a threat to the security of the United States? And what action should be taken in order to eliminate that threat to our security?

And I may say that we would not limit ourselves to the territorial space of the United States in making that determination.

We do the same thing out over the open sea.

Mr. FORD. That is the next point I was going to ask:

We would take the same position as far as any Soviet submarine which we knew had a military offensive capability?

Mr. BECKER. Precisely.

Mr. FORD. That is all, Mr. Chairman.

Thank you.

Mr. HAYS. I feel that this has been an imposition on you, but it is a great compliment that we have had this long session.

Will you accept the apologies of the committee? It was our eagerness to hear you and get all the information that we could.

Mr. Feldman has some questions to propound which you can answer later at your leisure.

Mr. FELDMAN. I think Congressman Keating also has some additional questions that he will submit for the record. I am sure that he would appreciate and the committee would appreciate the answers to those questions as best you can give them.

I will submit them to be copied into the record at this point.

(The questions are as follows:)

1. Can national sovereignty in outer space be unlimited?

(*a*) In view of the earth's rotation and revolution around the sun and the movement of the solar system, would it be possible in practice to determine national sovereignty in outer space by the maxim, "Cuius est solum, eius est usque ad coelum"—that is, could zones of sovereignty be established that would not overlap?

(*b*) If (*a*) is answered "yes," how would you determine jurisdiction over celestial bodies passing from time to time through different zones of sovereignty?

2. If the first question is answered "no," what criteria should determine the limits of national sovereignty in superjacent space?

3 Applying the criteria developed in the second question, how high, in your opinion, should national sovereignty extend?

4 In your opinion, what should the legal consequences be, if a space vehicle belonging to one nation entered the zone of sovereignty of another nation? For example, would the second nation be free to shoot down or to confiscate the space vehicle?

5. Assuming that the first question is answered "no," how many legally distinguishable zones of space would be necessary (e. g., a zone of national sovereignty, an intermediate zone in which there would be a right of innocent passage, and a third zone in which all passage would be unrestricted)?

6. By what means would you establish a rule of national sovereignty for outer space—by unilateral United States declaration, by treaties or executive agreements, through the U. N.?

7. Is there a need now for a rule concerning territorial claims on other celestial bodies, such as the moon? If so, what rule do you suggest?

8. What rule would you apply to the rights of private property owners in superjacent space?

9. In your opinion, should there be liability without fault for damage caused by manmade objects falling from space?

10. The only criteria mentioned in your statement for determining the upper limits of airspace are—

(a) The upper limit of aerodynamic lift (50 miles);

(b) The lower limit of aerodynamic drag (70 miles) (see statement on p. 6).

Wouldn't national defense criteria be controlling (as they presumably were, historically, in suggesting the 3-mile limit in the law of the sea)?

11. Why do you assume (p. 7 of prepared statement) that freedom of outer space would be inconsistent with national sovereignty over the moon (or other celestial bodies)?

12. As to the inherent right of self-defense set forth in article 51 of the U. N. Charter, would you consider the passage of a foreign reconnaissance satellite over United States territory (say, at a height of 500 miles) an armed attack on the United States?

13. As to the argument that the definitions of "airspace" in United States domestic law ("* * * navigation in * * * the air * * *") would apply to missiles and satellites, would you say that a missile or a satellite was "navigating" when in free fall (or only during its upward passage through the air)? Is it really material whether an object is navigating or not?

14. Will it be necessary or advisable, in your opinion, to put the Space Agency on a broader basis than the national security (i. e., the war powers of Congress), in view of the purely peaceful functions, in addition to its military functions, which the agency is expected to perform? What other basis can you suggest? ("General welfare"—for what it is worth—is now included? Commerce? Foreign relations?).

15. The rule of sovereignty completely up into space raises the question of how such a rule could be enforced. From the practical standpoint, would it be possible to determine what area belongs to each country when 2,000 miles above the earth? Will not such a rule call for a showdown between the nations involved in space exploration unless there is an agreement?

Under such a rule could the United States in good conscience proceed with space experiments after IGY ends. Even if all space above a certain height is considered free and belonging to all nations, isn't the nation which is prepared to dominate this area in a position to dominate the world just as there have been countries who were strong because they could dominate the sea and/or the air?

Mr. Hays. The committee is adjourned until 2:30 o'clock this afternoon.

(The following material was submitted to the committee:)

ANSWERS OF MR. BECKER TO QUESTIONS PROPOUNDED BY THE COMMITTEE AND ITS STAFF

Questions by Mr. Fulton:

At page 2597 of the transcript, Mr. Fulton inquired:

"Is space policy foreign policy, as far as the United States Government is concerned?"

Answer. "What the United States Government should do with respect to the entirely new field of outer space—with its as yet unexplored potentiality—poses highly important questions of national policy and of defense policy. It also inevitably poses highly important questions of foreign policy.

"Putting aside for the moment technical questions of international law—such as how high does sovereignty extend—all nations, regardless of their present capabilities, have an interest in man's activities in space, and our space planning and policy formulation must take account of that fact."

At page 2597 of the transcript, Mr. Fulton also asked:

"Is this a Federal jurisdiction or a 48-State jurisdiction, with each State having sovereignty over its own territory?"

Answer "As respects outer space, I am not aware of any determination by either Federal or State authorities on this point. If the Congress, with adequate constitutional authority, preempts the field, it will become a Federal jurisdiction."

At page 2612 of the transcript, Mr. Fulton requested that Mr. Becker furnish for the record a summary of his testimony before the Foreign Affairs Committee, and, in addition, the Paris Convention of 1919 and the Chicago Convention of 1944, including summaries of the annexes thereto

Mr. Becker's testimony on the subject of outer space before the Foreign Affairs Committee on February 11, 1958, was given in executive session, so that he is not in a position to furnish the same.

There is attached to this supplementary statement a statement of Hon. Omar Burleson, chairman of the Subcommittee on National Security and Scientific Developments Affecting Foreign Policy, of the Committee on Foreign Affairs, which was issued on February 11, 1958, following Mr Becker's testimony. There are also attached to this supplementary statement the requested copies and summaries of the Paris Convention of 1919 and the Chicago Convention of 1944.

Questions by Mr. Feldman, director of the committee staff:

At page 2631 of the transcript, Mr. Feldman posed the following question, consisting of two parts, as follows:

"1 Can national sovereignty in outer space be unlimited?

"(*a*) In view of the earth's rotation and revolution around the sun and the movement of the solar system, would it be possible in practice to determine national sovereignty in outer space by the maxim 'Cuius est solum, eius est usque ad coelum'—that is, could zones of sovereignty be established that would not overlap?

"(*b*) If (*a*) is answered 'yes,' how would you determine jurisdiction over celestial bodies passing from time to time through different zones of sovereignty?"

Answer to (*a*) "In view of the earth's rotation and revolution around the sun and the movement of the solar system, a point in space does not maintain the same position with respect to subjacent territory on earth, so that determination of sovereignty by drawing a line straight up from a particular territory or border would mean as respects any particular point in space that a nation's claim to "sovereignty" would be temporary Nevertheless, it is not inconceivable that a state might assert the right to insist that objects or vehicles emanating from another state did not have a legal right to be in a point of space directly over its territory, during the period that point is over its territory, without its permission. Similarly, a state might claim temporary 'sovereignty' over celestial bodies passing through different zones with the rotation of the earth. This is not to say that the application of such a rule is either likely or desirable. However, if this were to be the law, it would mean that unless the nations of the earth reached some cooperative agreement with respect to the use of space or the celestial bodies, each of them would have a veto power upon such use by the others."

Answer to (*b*). "More study of the facts is required before offering a definitive answer to this question "

Question. Also at page 2631 of the transcript, Mr. Feldman inquired:

"2. If the first question is answered 'no,' what criteria should determine the limits of national sovereignty in superjacent space?"

Answer. "It was the import of my testimony that we require much additional study before we shall be prepared to determine what criteria should determine the limits of national sovereignty in superjacent space. My answer to this question is to the same effect."

Question. Also at page 2631, Mr. Feldman inquired:

"3. Applying the criteria developed in the second question, how high, in your opinion, should national sovereignty extend?"

Answer "My answer to the foregoing question constitutes my answer to this one As further indicated by my testimony, I am of the view that before we attempt to develop criteria as to national sovereignty in space, we should, in line with the proposals made by the President, the Secretary of State and our Ambassador to the United Nations, seek to reach agreement that space will be devoted to peaceful purposes "

Question. At page 2631 of the transcript, Mr Feldman also inquired:

"4. In your opinion, what should the legal consequences be, if a space vehicle belonging to one nation entered the zone of sovereignty of another nation? For example, would the second nation be free to shoot down or to confiscate the space vehicle?

Answer. "My answer to this question is to be found on pages 2550–2552, inclusive, of the transcript, at pages 2585–2587 there is a colloquy between Mr. Sisk and me, which also deals with this point."

Question. At pages 2631–2632 of the transcript, Mr. Feldman inquired:

"5 Assuming that the first question is answered 'no,' how many legally distinguishable zones of space would be necessary (e g., a zone of national sovereignty, an intermediate zone in which there would be a right of innocent passage, and a third zone in which all passage would be unrestricted)?"

Answer. "As indicated by my testimony in chief, I believe that we are not sufficiently informed as to the facts of space to be able to lay down detailed rules of the type suggested by this question."

Question At page 2632, Mr. Feldman inquired·

"6 By what means would you establish a rule of national sovereignty for outer space—by unilateral United States declaration, by treaties or executive agreements, through the United States?"

Answer. "In my view, the choice of means of establishing a rule of national sovereignty for outer space should be contingent upon the determination of the desired rule. Accordingly, the only comment I would make with respect to this question at this time is that the United Nations, as such, does not possess legislative authority in the field of international law, although it could serve as a forum for reaching an international agreement on the subject."

Question. At page 2632 of the transcript, Mr. Feldman inquired:

"7. Is there a need now for a rule concerning territorial claims on other celestial bodies, such as the moon? If so, what rule do you suggest?"

Answer. Since I do not believe that we have sufficient facts in order to determine what such a rule should be, I have nothing to suggest The primary need at this time is for agreement that the activities of man on the other celestial bodies shall be peaceful. If we could reach agreement on this point, the question of territorial claims could be deferred, as the United States has done in the case of the Antarctica "

Question. At page 2632 of the transcript, Mr. Feldman also asked:

"8. What rule would you apply to the rights of private property owners in superjacent space?"

Answer. "I have no rule to suggest at this time."

Question. At page 2632 of the transcript, Mr. Feldman asked:

"9. In your opinion, should there be liability without fault for damage caused by manmade objects falling from space?"

Answer. "My views are expressed at pages 2550–2552, inclusive, of the transcript, supplemented by the colloquy with Mr. Sisk at pages 2585–2587, inclusive. I have no comment on the private law aspects of this question."

Question. At page 2632 of the transcript, Mr. Feldman posed the following question:

"10. The only criteria mentioned in your statement for determining the upper limits of 'airspace' are:

"(*a*) the upper limit of aerodynamic lift (50 miles)

"(*b*) the lower limit of aerodynamic drag (70 miles) (see statement on p 6).

"Wouldn't national defense criteria be controlling (as they presumably were, historically, in suggesting the 3-mile limit in the law of the sea)?"

Answer. "I did not mention in my statement any criteria for determining the upper limits of 'airspace,' other than the possibility that airspace could be equated to the area around the earth in which atmosphere exists."

Question. At pages 2632–2633, Mr. Feldman asked

"11. Why do you assume (p 7 of prepared statement) that freedom of outer space would be inconsistent with national sovereignty over the moon (or other celestial bodies)?"

Answer. "The assumption referred to was not made by me "

Question At page 2633 of the transcript, Mr Feldman inquired

"12 As to the inherent right of self-defense set forth in article 51 of the U. N. Charter, would you consider the passage of a foreign reconnaissance satellite over United States territory (say, at a height of 500 miles) an 'armed attack' on the United States?"

Answer. "This is the type of question which, in my view, should not be answered hypothetically, but rather in the light of all the facts as they exist at the time. Moreover, such a determination is one of policy as well as one of law."

Question. At page 2633 of the transcript, Mr. Feldman asked:

"13. As to the argument that the definitions of 'airspace' in United States domestic law ('* * * navigation in * * * the air * * *') would apply to missiles

and satellites, would you say that a missile or a satellite was 'navigating' when in free fall (or only during its upward passage through the air)? Is it really material whether an object is navigating or not?"

Answer. "In view of the phraseology of the applicable United States statute, it is material whether an object is navigating or flying. In my view, navigating could be interpreted to include a missile or a satellite in free fall."

Question. At page 2633 of the transcript, Mr. Feldman asked:

"14. Will it be necessary or advisable, in your opinion, to put the Space Agency on a broader basis than the national security (i. e., the war powers of Congress), in view of the purely peaceful functions, in addition to its military functions, which the Agency is expected to perform? What other basis can you suggest? ('General welfare'—for what it is worth—is now included? Commerce? Foreign relations?)"

Answer. "I express no view on this question of internal rather than international law."

Question. At pages 2633–2634 of the transcript, Mr. Feldman asked:

"15. The rule of sovereignty completely up into space raises the question of how such a rule could be enforced. From the practical standpoint, would it be possible to determine what area belongs to each country when 2,000 miles above the earth? Will not such a rule call for a showdown between the nations involved in space exploration unless there is an agreement?

"Under such a rule could the United States in good conscience proceed with space experiments after IGY ends. Even if all space above a certain height is considered free and belonging to all nations, isn't the nation who is prepared to dominate this area in a position to dominate the world just as there have been countries who were strong because they could dominate the sea and/or the air?"

Answer. "As pointed out in my testimony in chief, I believe that the best practical approach is that advocated by the President, the Secretary of State, and our Ambassador to the United Nations, namely, that other interested nations agree with the United States that outer space will be devoted exclusively to peaceful purposes If such agreement can be reached, and in the course of such agreement there will have to be a definition of what are peaceful uses, the questions here suggested will not arise."

Answers of John C. Cooper to Questions Submitted by Mr. Feldman

(1) In answering the first question as to possible unlimited national outer space sovereignty and the other questions, I wish to suggest that these questions are proof of the need for a Space Agency authorized to conduct "continuing and long-range research" in the wide field of "problems of flight within and outside the earth's atmosphere " Any answers now given to these searching questions must be tentative. They should be studied by a group representing military, scientific, diplomatic, and legal points of view Broad policy recommendations would then be available to the Government to meet the greatest challenge of the present day—the peaceful use of outer space as a new highway for communication between the peoples of the world

Answering the specific question No. 1, the answer is "No," in the absence of wide and specific international agreement. In my Mexico City talk in 1951, (being put in the record at the request of Mr Fulton), I pointed out some of the reasons why unlimited sovereignty upward cannot be claimed. Sovereignty ordinarily must be coupled with reasonably effective continued occupation. As Huber said in the Island of Palmas Arbitration in the Tribunal of the Permanent Court of Arbitration, 1928: "Territorial sovereignty is, in general, a situation recognized and delimited in space, either by so-called natural frontiers as recognized by international law or by outward signs of delineation that are undisputed, or else by legal engagements entered into between interested neighbors, such as frontier conventions, or by acts of recognition of states within fixed boundaries * * * The growing insistence with which international law ever since the middle of the 18th century has demanded that the occupation shall be effective would be inconceivable if effectiveness were required only for the act of acqusition and not equally for the maintenance of the right."

Unlimited space sovereignty upward cannot conceivably meet these sound tests.

(2) Possible effective control so as to enforce national law is the primary limit of possible space sovereignty in areas seized or claimed without agreement. This test would not apply if general international agreements were reached to extend upward to a uniform height the territory of every subjacent state.

(3) In several recently published articles and addresses, (being put in the record at the request of members of the committee), I have suggested an agreement for an upper limit of about 300 miles, on the basis that this would include areas where "drag" affects free satellite flight, subject however to more information being available through the Geophysical Year activities as to the density of the upper atmosphere. I said recently, for example: "It seemed to me in 1956, and still does, that the subjacent state properly has sovereighty in the atmospheric area where airplanes and balloons can operate. These depend for their lift on the existence of fairly dense gaseous air in the true airspace. It also seemed then, and still does, that the area in which sufficient gaseous air exists to prevent free satellite flight might very well by agreement be deemed part of the airspace" (See p. 382, Journal of Air Law and Commerce, vol. 24, No. 4, autumn 1957 issue) As I have often said, the only agreement now existing is that sovereignty extends through the "airspace," and that the term "airspace" in the Paris convention of 1919 and the Chicago convention of 1944 was there meant to include only those parts of the atmosphere where gaseous air is sufficiently dense to provide aerodynamic lift for the only types of aircraft then in existence.

(4) Every state has the right to exclude all flight instrumentalities from its sovereign territorial space. Whether it would be justified in shooting down the intruder might depend on particular circumstances A similar problem as to aircraft intrusion is now before the World Court.

(5) Please see my suggestions as to three zones, recently restated in "Missiles and Satellites—The Law and National Policy," page 320, American Bar Association Journal, April 1958, vol. 44

(6) It would be preferable to fix the upward limit of national sovereignty by a new convention, adopted at a diplomatic conference, convened after careful advance preparation.

(7) Yes, an immediate declaration of policy should be made that the moon is "res communis"—not subiect to seizure by any individual state. Its intimate relationship with life on the earth through influence on tides and other physical phenomena on the earth, its possible future use—all show the need foı immediate recognition of its nonnational status. The United States should declare that the moon is open for exploration for the benefit of all, but that seizure would be an act of aggression against the interests of the international community

(8) The very limited upward rights of private owners were, in my judgment, clearly stated, so far as American law is concerned, in the Causby case decided by our Supreme Court in 1946 (328 U. S. 256). The Court held that the old "cujus est solum" doctrine "has no place in the modern world."

(9) The answer is "Yes"—this is the generally accepted modern rule.

(10) The solutions appearing in my original statement dealt with bases on which I felt agreement might be reached as to the upper limit of sovereignty. Certainly national defense criteria would also be considered before the United States took any final position—again indicating the advisibility of long-range research to explore every avenue of approach toward solution of our space problems.

(11) My original statement as to the moon was not properly framed. I have amended the statement on page 2532 of the transcript to show that I was discussing future international agreement. However, my views as to the necessity of separately declaring that the moon is "res communis" are amplified above in answering question No. 7

(12) This involves a Government military policy decision which I do not feel qualified to answer.

(13) As I said in my original statement, satellites and spaceships, in my judgment, are not within the definition of "aircraft" in the Air Commerce Act. Doubt certainly exists as to whether rockets or missiles are included. They are generally, so I am advised, designed for flight beyond the "air"—not in the "air."

(14) The constitutional basis for space agency legislation should be put on as broad a foundation as possible—particularly as to potential commerce, and effect on foreign relations.

(15) See my answer to question No. 1. In my judgment, mere military power to shoot down a foreign satellite at some great height is not the kind of continued effective occupation which a show of national sovereign control will demand. The latter part of the question raises again what I tried to indicate at the hearing—we may be faced with a crisis after the IGY year in view of the fact that the United States (as I understood Mr. Becker's testimony), has not committed itself as to whether future satellite upper space flights do or do not violate the territorial space of subjacent states.

Questions By Representative Keating

QUESTIONS FOR WITNESSES (NATIONAL SOVEREIGNTY IN OUTER SPACE)

1. Has our scientific progress into space raised legal problems which are so serious and imminent that we should take steps to meet them now?
2. Would it be better to "wait and see" before we begin to formulate the rules of the road?
3. Could the application of existing laws or treaties determine who owns space or certain parts of it?
4. Has the principle established at the Paris Convention of 1919—that every power has complete and exclusive sovereignty over the airspace above its territory—been rendered obsolete?
(a) What is the accepted meaning of the term "airspace"?
(b) Does this term need redefining?
(c) Do we need new terms to establish zones in which different rules should govern?
5. Would you favor the application of the law of the high seas to outer space?
6 Do you believe that by our participation in the IGY satellite program we in effect gave informal recognition to the principle of freedom of outer space?
7 Do you think the United States should make a formal "freedom of outer space declaration" now?
8. Do you favor an international agreement that outer space be the common property of all nations? Should this be accomplished through the U. N.?
9. Do you think some international organization, such as the U. N., should control outer space? Is it too early to push for this now?
10 Do you believe that the exploration of outer space should be conducted on an international level through some agency such as the U. N.?
11 What steps do you think the United States should take now to bar the use of outer space for military purposes?
(a) Should we press for negotiations now?
(b) Through the U. N.?
(c) Have you thought of any sort of inspection system as a safeguard?
(d) How could it best be enforced?
12. What is the present international law with respect to occupation and discovery?
13. Is this law suitable or adaptable to discoveries of and landings on celestial bodies such as the moon or Mars?
14. What new laws do you think are necessary? To avoid future disputes should they be agreed upon now? Can this best be accomplished through the U. N. or by negotiations and treaties outside the U. N.?
15. Would you favor international control of these celestial bodies? By the U. N.?
16. Has thought been given to the possibility that these bodies may be inhabited? How would we deal with intellectual beings?
17. With satellites orbiting the earth, and with talk of rockets to the moon, space platforms and other vehicles in space, are present laws adequate to govern problems of rights and liabilities as between nations, and between nations and individuals that may arise?
(a) What about liability for midair collisions, misguided missiles, etc?
(b) What about the rights of a launching nation to a downed satellite or rocket?
18 Does space travel pose any legal problems with respect to communications, navigation, air routes and terminals, and traffic control?
19. What action should Congress take now to meet and solve these problems?
(a) Would you favor a separate, special committee or joint committee devoted to the legal as distinguished from the scientific aspects of space exploration?
(b) Or should these problems be handled by one committee devoted to all space problems?
20 In view of the international character of so many of those problems, should they be left to the State Department to solve through the normal diplomatic channels?
21. If you believe the legal problems should be handled by the Space Agency suggested by the President, or one similar to it, should special provision be made for negotiation of these matters by the State Department?
22. The civilian space agency bill refers to terms such as "outside the earth's atmosphere", but does not define them Should there be definitions written into the bill?

ANSWERS OF JOHN C. COOPER TO MR. KEATING'S QUESTIONS

(1) Satellite launchings, in my judgment, require early decisions as to the legal status of the areas in which satellites are put in orbit. If such areas are part of territorial space, one set of principles will apply dealing with the well-established rules applicable to the right of each state to control movement in its territory. If such areas are not territorial space, a beginning should be made as to how, when, and by whom applicable rules should be adopted and then enforced

(2) It is too early to formulate rules of the road. I prefer Professor McDougal's Modest Proposal, as outlined in the January 1957 American Journal of International Law (vol. 51, No. 1, p. 74, text p. 77) where he suggested, as a beginning, the following program· "each state about to launch a satellite to register its intent to do so with an international agency, to file a flight plan with such agency, and to file a description of the satellite's load, weight, size, etc "

(3) Existing laws and treaties are not much help without an agreed definition of "airspace."

(4) The principle of airspace sovereignty should still stand

(*a*) As to my view of what the Paris convention meant by "airspace," see my answer to Mr. Feldman's question No. 3.

(*b*) The term has never been defined

(*c*) I prefer new terms, I would particularly prefer to use "territorial space" instead of "airspace" to define the areas in which the state below has complete and absolute sovereignty.

(5) The law of the high seas as to rights of freedom of navigation and rights of self-defense and self-protection could be applied to the areas of space beyond territorial space. Beyond this there may be difficulty in applying sea law to usable space

(6) The legal effect of the course of conduct of the United States in participating in the IGY satellite program presents grave difficulties As I pointed out at the American Bar Association meeting last February, "international conduct during the past 3 years is leading to the acceptance of the rule that areas of space, where there is not atmosphere of sufficient density to create drag or otherwise affect flight, are beyond the sovereignty of any state " Certain European jurists have expressed the categorical opinion that the freedom of "outer space" has now been accepted. In this connection Mr. Becker's testimony is of major importance. It is the first authoritative statement which I have seen that the United States does not feel itself committed for the future beyond the IGY. This should be carefully noted by the committee.

(7) First there must be a definition of outer space by the United States, then all of the problems involved from political, military, and legal points of view need full examination I would prefer to see the Space Agency set up before the United States commits itself further

(8) Yes, if by "common property" is meant that it is open to permanent peaceful use by all members of the international community. Since the breakdown of the Geneva Sea Law Conference, I am not as much in favor as I once was of a U. N. agreement as the bases of future action

(9) Too early, in my judgment, to determine how future control should be exercised

(10) For the present I would prefer national exploration under a general agreement banning military use

(11) I would prefer a diplomatic conference after careful preparation. The type of practical inspection system to be established needs extensive further study.

(12) Please see my answer to Mr. Feldman's question No. 1. My own view is that Huber's opinion in the Island of Palmas case is still the best statement of the law as I understand it.

(13) Probably, unless, as I hope, an early decision will be made that the moon is "res communis" and therefore outside the category of lands that may be occupied as new national territory. Also doubt must exist as to whether anyone could "discover" the moon—even its nonvisible side

(14) My primary concern is an early decision as to the extent upward of territorial space. Until then, other new laws might be useless.

(15) By an international agency to permit freedom of exploration—not seizure or other use for national purposes.

(16) Have given the matter no consideration.

(17) (*a*) Rules of the road must eventually be worked out, and also liability questions. One of the most difficult questions will be to differentiate between rules in territorial space and in outer space. Particular consideration must be

given to the powers of the International Civil Aviation Organization to adopt binding rules for aircraft flight over the high seas under article 12 of the Chicago convention. A decision must be made as to how high these rules will apply and as to what flight instrumentalities will be included.

(b) While property rights may be reserved, certainly any international inspection system should permit the state where the satellite or rocket has landed to make a full examination of the fallen object.

(18) Extremely difficult problems; for example, use of designated radio frequencies, plain codes for communication as a part of any inspection system, noninterference with other forms of flight when leaving or arriving on the earth, etc.

(19) I am strongly in favor of a single agency to study the political, legal, and scientific questions.

(20) and (21) A properly constituted Space Agency should study all of these problems and make its recommendations to the President. Such diplomatic action as he might determine would be implemented through the State Department.

(22) The term "atmosphere" is very vague and unsatisfactory. I would prefer "territorial space" and "outer space" with mutually exclusive definitions. It has been estimated that stray molecules of gaseous air may exist at vast distances out into space. If this is what is meant by "atmosphere," the term "outside the earth's atmosphere" is legally useless.

Outline of Testimony of Loftus Becker, the Legal Adviser of the State Department

1. Is there any accepted principle of international laws relating to space?

There is. Under article 51 of the United Nations Charter, the members of the United Nations expressly reserved their "inherent right" of individual or collective self defense against armed attack.

The origin of an armed attack against the United States or the particular point in space through which it would have to pass in order to reach the United States (or one of its collective security allies) is immaterial. The United States is, of course, prepared at all times to react in order to defend itself against an armed attack, even though such attack might originate in territory or in airspace which we recognize as being subject to the sovereignty of another state. A fortiori the United States is prepared to defend itself against an armed attack originating in, or passing through, space outside the earth's atmosphere. If and when the United States takes such action, it will be exercising not a unilaterally asserted right, but rather a right established by accepted international law, as defined in the charter of the United Nations.

2. Has the United States recognized any top or upper limit to its sovereignty?

The answer is "No."

Entirely aside from article 51 of the United Nations Charter, the United States has never taken the position that its sovereignty (or any related rights that it might assert) has an upper limit.

A number of commentators have laid great emphasis upon the fact that such international agreements as the Chicago Convention of 1944 (TIAS 1591), like the earlier Paris Convention of 1919 (11 LNTS 173), recognized that each of the parties thereto "* * * has complete and exclusive sovereignty of the air space above its territory." From this they infer a negation of the principle that any state has sovereignty over space outside the "airspace" above its territory. I cannot agree that the significance of international agreement upon a principle such as this can be evaluated without regard for the context in which it was made the subject of agreement. To stipulate that a state has "complete and exclusive" sovereignty within certain defined limits is not to say that it has no rights above those limits; the only reasonable inference from such a statement is that no agreement has been reached as to what, if any, rights may be recognized above such limits.

It is important to note that there is nowhere in the Chicago Convention of 1944, or other international agreements comparable thereto, any definition of what is meant by the term "airspace."

A number of those who have commented on what should be the law of space have suggested definitions for this term. I do not wish to take, nor has the State Department ever officially taken, a definitive position as to how this term "airspace" should be defined. I think, it important to note, however, that one of the suggestions that has been made in this regard is that the "airspace" should be

defined to include that portion of space above the earth in which there is any "atmosphere." I am informed that astronomically the earth's "atmosphere" extends 10,000 miles above its surface. While the Department of State has taken no position upon this question, I do think it important to point out that one rational definition of "airspace" would enable us to maintain that there is a body of international law applicable up to 10,000 miles from the surface of the earth. That would seem to afford us sufficient elbow room for discussion.

It is therefore important to note that although the United States in its domestic law, as well as in such international agreements as the Chicago Convention of 1944, has plainly asserted its "complete and exclusive sovereignty over the airspace above its territory," the United States has at no time conceded that it had no rights in the higher regions of space.

One rationale for this position, which seems to me self-sufficient, was that the United States had no need to define its position with respect to what rights, if any, it might possess outside the earth's atmosphere until such time as mankind had demonstrated a capability of existing outside the atmosphere.

Even after such a capability is demonstrated, there will be no imperative requirement in international law that the United States make any claims of sovereignty in order to protect its rights.

An apt analogy is afforded by the Antarctic. There, for many, many years, the United States has been engaged in activities which, under established principles of international law, without any question whatsoever, created rights upon which the United States would be justified in asserting territorial claims, that is to say, claims to sovereignty over one or more areas of the Antarctic. Notwithstanding this fact, the United States has not asserted any claim of sovereignty over any portion of Antarctica, although the United States has, at the same time, made it plain that it did not recognize any such claims made by other States Nonetheless, the United States has been consistent in asserting that under international law and practice, its activities on the Antarctic continent have entitled it to rights in that area which it has at all times expressly reserved. It is the position of your Government, and, I believe one well founded in international law, that the fact the United States has not based a claim of sovereignty over one or more areas of Antarctica upon the activities it has engaged there, in no way derogates from the rights that were established by such activities

So, too, in outer space, the United States has already engaged in activities which, it could be asserted, have given to it certain rights, as distinguished from those States who have not engaged in such activities. Up to this time, the United States has made no claims based upon such activities. As in the situation with respect to Antarctica, this should not be interpreted as any concession of any kind whatsoever on the part of the United States that its activities have not given it certain rights in space which, in turn, could be relied upon as the basis of claims of sovereignty.

3. Should the law of space be codified at this time?

The President, the Secretary of State, and Ambassador Lodge have several times suggested to the U. S. S. R , which, to date, is the only other state that has demonstrated a capability of placing objects in orbit in space, that we consult with the objective of insuring that mankind's activities in space be devoted exclusively to peaceful purposes. These proposals have included any and all activities in space, whether or not they involved putting an object in orbit. To the extent envisaged by these proposals, we believe that the sooner that agreement is reached, the better.

As you know, the tendency of development of the common law, as applied in the United Kingdom and the United States and in a number of other countries, has been on a case to case basis Speaking very generally, it has been felt that the soundest way to progress in the extremely complex field of the law is by means of specific decisions, on specific questions, presented by specific fact situations.

Even in those States which apply the principles of the civil law, it is recognized that a body of law can only be created upon a broader body of ascertained fact.

Moreover, there are very great risks in attempting to transmute a body of law based upon one determined set of facts into a body of law with respect to which the basic facts have not been determined. Accordingly, we view with great reserve any suggestion that the principles of the law of the sea should, prior to the ascertaining of many more facts with respect to conditions in space, become the law of space.

Basically, it is the position of our Government that the law of space should be based upon the facts of space and that there is very much more that we have to

learn about the conditions existing in space, before we shall be in a position to say what shall be the legal principles applicable thereto.

4. The significance of a definition of the airspace

Many commentators have suggested that it is imperative that at the earliest possible moment we shall have an internationally agreed upon definition of airspace. This assertion is related to the suggestion that such definition is requisite in order to delimit areas of national sovereignty. I believe that from what I have already stated, it will be apparent that I do not share in this view, nor has the United States Government ever conceded that its sovereignty upward was restricted to the airspace above its territory There are other aspects of this question, with respect to which the significance of this dividing line may be less important that has heretofore been asserted

Public announcement has been made of an "X-15" which is designed to operate both inside and outside the earth's atmosphere as defined by some of the commentators Moreover, all objects which orbit around the earth, whether or not they do so within or outside the atmosphere, or partly within and partly outside the atmosphere, have characteristics of operation which distinguish them sharply from other objects which may, for a period of time, pass through space.

As you are undoubtedly well aware, a number of systems of private law relate to the characteristics of the activities upon which one is engaged. For example, in our own law we have one set of rules applicable to the activity of mining, another applicable to the extraction of petroleum and like materials, and still another applicable to subsurface waters, although all three activities, in general, relate to man's actions or interests below the surface of the earth

Here again, one of the possibilities to which we shall have to give serious consideration is whether the performance of a particular space vehicle is sufficiently distinguishable so as to justify applying to it a set of rules which are different and distinct from those that we apply to other space vehicles having different operating characteristics.

To take an analogy from the law of the sea, while there have been certain principles applicable to all seagoing vessels, there has always been a distinction between the rules applied to sailboats and those applied to boats propelled by one or another method of mechanical propulsion.

5. Property rights

A number of commentators have stressed the necessity of developing an internationally recognized set of principles of property rights applicable to space vehicles Two of the questions frequently raised are first, as to the right of the subjacent state to protect itself from injury from such a vehicle landing on its surface or its inhabitants, or second, as to the right of such a state to damages for injury resulting from such activities. Another question in this regard which has been recently discussed in the press in connection with the Soviet claim that a portion of its satellite had landed on United States soil, was whether or not the state which initiates the flight of a space vehicle retains a property right in such vehicle in the event that it comes to earth again.

Although there is no generally accepted international code with respect to space vehicles as such, I would suggest that existing international law provides a set of principles which could be made applicable, until such time as we find it necessary to recognize specialized principles.

Assuming that the problem of reentry has been overcome, so that a space vehicle does not disintegrate before returning to earth, such a vehicle must, of necessity, pass through the airspace in order to return to earth. It is a recognized principle of international law that the sovereignty of a state with respect to the airspace over its territory and its territorial seas is complete and exclusive. This means that the vessels of another state, including those which are unmanned as well as those that are manned, are not entitled to enter upon such airspace without the permission of the sovereign state.

If the permission of the subjacent state is to be obtained, it may be conditioned by undertakings with respect to liability for any damage which may result therefrom. If it is not obtained, the tortious nature of the entry upon the airspace of the subjacent state would seem to make the initiating state a guarantor with respect to any damage resulting from its unjustified activity.

As respects the ownership of a space vehicle returning to earth, some commentators have suggested that, at least as respects unmanned space vehicles, the appropriate analogy is the bullet, ownership of which is abandoned by the act of firing. An alternative rationale would be that any such vehicle entering the airspace of a sovereign state without the latter's permission should be placed

in the category of smuggled goods which may not only be confiscated upon discovery, but with respect to which action may be taken outside the territory or the territorial waters of the state in which the same are to be introduced.

INTERNATIONAL AIR LAW

A lecture delivered by Mr. John C. Cooper, Member, Institute for Advanced Study, Princeton, N. J., at the United States Naval War College, Newport, R. I., December 20, 1948

Air law has been defined as "the whole of the rules which govern the airspace and its utilization for the purpose of aviation" (Goedhuis, Air Law in the Making, The Hague, Nijhoff, 1938) The difficulty with this definition today is that technical progress now requires that we consider both airspace and certain parts of space beyond as scientifically practical mediums of flight Nor can we limit the means of flight with which air law must deal to such instrumentalities as the normal types of aircraft usually operated in the "airspace." Rockets are now being propelled seventy miles and more into space above the surface of the earth, far outside of what we ordinarily refer to as "airspace" and its "atmosphere" It is suggested that the term "flight space" might better be used in place of airspace to indicate all that space above the earth's surface used or usable as a medium of man-made or controlled flight. Perhaps the definition of air law might then be restated as "comprising the whole of the rules governing flight space and its utilization as a medium of flight for aircraft or other self-propelled and man-controlled devices."

Such a definition has the advantage of directing attention to the two basic problems of air law—its concern with the legal status of space and the legal regulation of flight. It is obvious that until we know whether flight space is part of the national territory of the state lying below it, or free of all control and usable by all states, it is quite impossible to determine the rules applicable to the regulation of flight in such space. Hence air law must first determine the legal status of flight space over the various parts of the earth's surface, such as the national territory of sovereign states below and the high seas, and having determined such status, it must then provide the rules for the regulation of flight.

As to the first of these problems, it is the function of international air law, as law governing the relations between states, to determine what parts of flight space can become or are parts of the territory of sovereign states and what parts of such space must be free for the use of all peoples. Exactly the same problem developed in the law of the seas Complete confusion and strife existed between nations as to the right to control the high seas until customary international law was tacitly accepted under which it is now agreed that the high seas are not and cannot become part of the sovereign territory of any state and must be open and free to the navigation of all states. As pointed out by Kelsen (General Theory of Law and State, Cambridge, Mass., Harv Univ Press, 1945, p 349) "each state can claim as its 'territory' only a part of space and as its people only a part of mankind." Any interference by one state with these spheres of another state is a violation of the rights of the other state Hence no single state can determine what part of space is of the character which it has the right to include within its territory, and only international law, which governs the relations between states, can provide the applicable rules.

International air law has recognized these problems It has sought first to determine rules acceptable to the community of states as to the legal status of flight space and then provide international regulations of flight through such space as is not part of the territory of individual states, and also, by such international legislation to provide certain rules to be applied by all states even as to flight within their territorial flight space Agreement exists as to the principles covering the legal status of the "airspace." The problem is new as to the legal status of space beyond the airspace. Agreement also exists among most states as to rules regulating flight in time of peace. No substantial agreement exists as to such regulation in time of war.

To demonstrate the existence and nonexistence of international air law covering these various spheres of international relations, an examination of the Convention on International Civil Aviation signed at Chicago in 1944 and now in effect will be useful.

LEGAL STATUS OF FLIGHT-SPACE

The Chicago convention is now in force between most of the nations of the world with the notable exception of the Soviet Union. Articles 1 and 2 of that convention state presently accepted international air law as to the legal status of the airspace:

"*Article 1.*—The contracting states recognize that every state has complete and exclusive sovereignty over the airspace above its territory.

"*Article 2.*—For the purposes of this Convention the territory of a state shall be deemed to be the land areas and territorial waters adjacent thereto under the sovereignty, suzerainty, protection, or mandate of such state."

Several things are noteworthy in these articles: (*a*) They state existing International air law and do not legislatively create such law, because they recognize that "every state" whether a contracting state or not has exclusive airspace sovereignty over its territory; (*b*) there is no limitation as to applicability in peace or in war—it being clearly inherent in the convention that these statements apply in both, (*c*) No statement is made as to the status of airspace over the high seas.

The background history of these articles and the principles which they state are well known About the beginning of the present century, when control of flight through the development of dirigibles became a real possibility, an eminent French lawyer, Fauchille, raised the question as to whether states have territory in the air as well as on land and on water. An historic controversy developed, the details of which cannot be considered here, between the proponents of national sovereignty in the airspace and those who insisted that it should be free to air navigation as the high seas were free to surface navigation. No better statement of this controversy exists than that made by Prof. George Grafton Wilson in the Naval War College, International Law Situations for 1912 (pp. 68–70):

"The ideas in regard to the limits of aerial jurisdiction set forth by those who are giving special attention to this subject are not, however, in accord. It is natural that one group should maintain the ancient doctrine that 'the air is free.' Another group maintains that the domain of the air is exclusively in the subjacent state. A third group, between these, maintains that a certain zone of atmosphere above a state is within its jurisdiction, and beyond this the air is free. The height of this zone of jurisdiction is, however, a subject of considerable difference of opinion

"The argument has been advanced that the aerial domain of a state should be limited to a certain distance above its territory. It has been stated that the altitude which an airship might attain can be determined, but as the limits fixed in earlier estimates have been surpassed it seems unwise to attempt at present to establish such limits.

"Some think the height of the zone can be determined in a manner analogous to that of determining maritime jurisdiction. Some see unsurmountable difficulties in the use of this analogy. Of those who favor a zone theory some propose that the zone be determined by the limit of vision; some that the limit of effective control by arms be the determining factor; some that an arbitrary limit be agreed upon by the states of the world, and others advance other propositions."

The discussions to which Professor Wilson had reference were largely between lawyers. In a careful reexamination of practically all of the available material, beginning with the invention of the balloon in 1783 and continuing until World War I, I have been able to find no occasion in which a sovereign state disclaimed sovereignty in its airspace. It is my judgment that such sovereignty has always existed. In this view I think that I am supported by the great authority of Professor Wilson. In the same Naval War College publication referred to above, he noted the fact that regulations issued by state authority make it evident "that states assume that they have jurisdiction in the airspace above their territory." In summarizing his views and basing his remarks on a quotation from a decision by Mr. Justice Story in *Santissima Trinidad* (7 Wheaton 354) and repeating what he had said in a paper read before the American Political Science Association in 1910 (Aerial Jurisdiction, V American Political Science *Review*, 1911, p. 171), Professor Wilson said:

"It would seem that physical safety, military necessity, the enforcement of police, revenue, and sanitary regulations justify the claim that a state has jurisdiction in aerial space above its territory. This position also seems to underlie established domestic law and regulations, the decisions of national courts, the conclusions of international conferences, and the provisions of international conventions.

"It would seem wise, therefore, to start from the premise that air above the high seas and territory that is res nullius is free, while other air is within the jurisdiction of the subjacent state 'and that the exceptions to this rule are such only as by common usage and public policy have been allowed, in order to preserve the peace and harmony of nations and to regulate their intercourse, in a manner best suited to their dignity and rights,' and for these exceptions to the exclusive right of aerial jurisdiction of the subjacent state, international conferences should by agreement immediately provide" (Naval War College, International Law Situations, 1912, p. 71–72).

This remarkable statement, first made in 1910 and repeated in 1912, analyzes the basic question of international air law as it is now understood.

The first attempt at the Paris Conference of 1910 to agree on rules of flight was unsuccessful. At that conference there was wide difference between certain of the nations present as to the extent to which foreign aircraft might have privileges of flight in the airspace over national territory of the European governments which took part in the conference. But no government was there prepared to accept the theory that the airspace over its territory was not part of the domain and thereby not subject to its control. An examination of the minutes of this conference will bear out the statement just made (Conference internationale de navigation aerienne, Paris, May-June, 1910, Proces-verbaux de seances et annexes).

The concrete acts of the great European powers later affirmed their earlias apparent insistence on airspace sovereignty. Great Britain, in the Air Navigation Acts of 1911 and 1913, proclaimed its right to set up various prohibited areas in its airspace where no foreign aircraft might fly and to control the terms under which any foreign aircraft might otherwise enter the airspace over British surface territory. By an exchange of notes in 1913 between the French and German Governments, it was agreed that military aircraft of one nation could enter the airspace of another only on invitation, and that civil aircraft of one nation must obtain a special permit from a consul of the other nation before starting out on a trip to the latter's territory. Provisions were also included for prohibited areas over which the aircraft of the other nation could never fly.

The British Air Navigation Acts and the French-German air traffic agreement could not have been entered into except on the theory that each of these powers claimed the full right to control, as against other nations, the airspace over its land territory. This is the exercise of external or national sovereignty in international law.

The outbreak of World War I affirmed the continued claim of airspace sovereignty by the European nations In a letter handed by the German Ambassador to the French Foreign Minister on August 3, 1914, in which it was stated that the German Empire considered itself at war with France, one of the alleged hostile acts charged by Germany to be one of the direct causes of war was the fact that French military aviators were said to have been guilty of hostile acts on German territory and that they had "openly violated the neutrality of Belgium by flying over the territory of that country." In other words, Germany insisted that the airspace over Germany was part of German territory and that the airspace over Belgium was part of Belgian territory—that the flight of French aircraft into Belgian airspace, even without performing any hostile acts against the Belgian inhabitants, constituted an invasion of Belgian territory and a violation of Belgian sovereignty and its internationally guaranteed neutrality

Immediately after the outbreak of war, various nations of Europe closed their air boundaries. During the course of the war neutral states required foreign belligerent aircraft flying into their airspace to land and be interned just as they also required foot soldiers, under international rules of war, to be interned when they crossed land boundaries into neutral territory

During the meeting of the Peace Conference following World War I, an aeronautical commission was organized and charged with preparing a convention for the regulation of air navigation Its Legal Subcommission (on which the United States was represented) in submitting a draft of the proposed convention, made the following authoritative statements in its report:

"The first question placed before the Subcommission was that of the Principle of freedom or of sovereignty of the air

"* * * the opinion expressed in the Legal Subcommission is favorable to the full and exclusive submission of the airspace to the sovereignty of the subjacent territory. It is only when the column of air hangs over a res nullius or communis, the sea, that freedom becomes the law of the air

"Therefore, the airspace is part of the legal regime of the subjacent territory. Is this territory that of a particular state? Then the airspace is subject to the sovereignty of that state. Does it escape all sovereignty as the free sea? Then the airspace is also free above the sea, as the sea itself

"It results then that, by virtue of its sovereignty, the subjacent state, within its borders, can forbid flight and, with greater reason, landing."

The convention drafted by this Subcommission of the Aeronautical Commission was signed and came into effect as the Paris Convention of 1919 "relating to the regulation of aerial navigation." It stated in article 1 the basic problem of airspace sovereignty:

"The high contracting parties recognize that every power has complete and exclusive sovereignty over the airspace above its territory.

"For the purpose of the present Convention the territory of a state shall be understood as including the national territory, both that of the mother country and of the colonies, and the territorial waters adjacent thereto "

The United States was represented on the Aeronautical Commission and took an active part in insisting on the adoption of the theory of airspace sovereignty. Its delegates signed the convention, but for various reasons, particularly because of the indirect relation between the Paris Convention and other treaties acknowledging the authority of the League of Nations, the Paris Convention was not ratified by the United States This nonratification had nothing to do with the acknowledgment by the convention of airspace sovereignty as the fundamental precept of international air law The convention was later ratified or adhered to by most of the nations of Europe except the Soviet Union and Germany, also by the British Dominions and Japan, and certain Latin American countries. Both Germany and the Soviet Union, through separate statutes insisted on airspace sovereignty and their consequent right to admit or exclude foreign aircraft into their territorial airspace

Such was also the position of the United States. Every recorded official act of the United States Government has indicated its complete acceptance of the doctrine of airspace sovereignty and its insistence on its right as a sovereign state as against foreign nations to determine whether the aircraft of such foreign nations may be admitted to or excluded from use of the airspace over the United States. In 1916, for example, the United States took part at an inter-American conference at Santiago, Chile, at which resolutions were adopted providing that states should have sovereign rights in the airspace over their respective territories. During World War I, on February 18, 1918, President Wilson issued a proclamation inaugurating a licensing system under which no flight could take place except pursuant to a license to be issued by a joint Army and Navy board if the flight was to pass over or near military installations "or any place or region within the jurisdiction or occupation of the United States which may be designated by the President as a zone of warlike operations or of warlike preparations " In the same proclamation, the President designated as a zone of military operations and preparation the whole of the United States and its territorial waters and insular possessions In other words, the proclamation assumed complete national control over all the airspace above the lands and waters of the United States.

To the same effect were the provisions of the Air Commerce Act of 1926, the first Federal statute regulating flight in interstate and foreign commerce. In section 6 of that statute is included a congressional declaration "that the Government of the United States has to the exclusion of all foreign nations complete sovereignty of the airspace over the lands and waters of the United States including the Canal Zone " In the House Report 572, 69th Congress, 1st session in which the bill was reported which became the Air Commerce Act of 1926, it is pointed out the "the legal features of the bill have their foundation in existing principles of law," and that "the declaration of the sovereignty of the United States as against foreign nations in the airspace above the United States is based upon a similar declaration found in the International Air Navigation Convention " In other words, the United States, although it did not ratify the Paris Convention, accepted the statements in article 1 of that convention as to airspace sovereignty as being a correct acknowledgment of the existence of a principle of customary international law

No legislative action in the United States has subsequently in any manner affected or changed this policy As a matter of fact the policy has been reaffirmed.

In 1928 the United States assisted in drafting and later signed and ratified the Havana Convention known as the Pan American Convention on Commercial Aviation which in article 1 recognizes "that every state has complete and exclusive sovereignty over the airspace above its territory and territorial waters." Again in 1938, by the adoption of the Civil Aeronautics Act, the same principle was affirmed

It is apparent from this recapitulation of the development of international air law airspace sovereignty principles up to and including the adoption of the Chicago Convention that certain rules may now be considered in force:

(1) Each state has complete and exclusive sovereignty over the airspace above its territory

Airspace as here stated is believed to mean only that part of space which is filled with air and not the space beyond In commenting on the legal history of the Air Commerce Act of 1926, Mr Frederic P. Lee, legislative counsel for the

United States Senate at the time of the adoption of the act, indicates that the term "airspace" should be construed as that part of space above the earth's surface filled with air and that any interpretation of the term "airspace" "other that such literal interpretation involves the construing of airspace as synonymous with space." (Civil Aeronautics. Legislative History of Air Commerce Act of 1926, corrected to August 1, 1928 Washington, U. S. Government Printing Office, 1943.) If all space was intended, the results are absurd. Therefore, no international air law can be said to govern at this time the use of space beyond the airspace and the problem requires future international consideration. Perhaps by analogy the rules now existing in airspace may be extended beyond into such additional areas of flightspace as are reasonably subject to control by the subjacent State.

(2) Territory, for the purposes of airspace sovereignty, includes territorial waters and territory under mandates

Airspace over territorial waters is in exactly the same status as airspace over land territory. No privilege, right or easement is acknowledged in favor of foreign aircraft in such airspace over territorial waters. International air law has not accepted the doctrine of innocent passage which gives foreign surface ships certain rights of passage in territorial waters, without specific agreement of the adjacent sovereign state. As a result the air boundaries of a state are at the edge of its territorial waters and no aircraft of a foreign state may fly into such airspace over territorial waters without the specific permission of the adjacent state. This indicates the danger in seeking to create rules of air law by analogy from rules of maritime law

The Chicago convention was adopted before the United Nations Charter was adopted at San Francisco The Chicago convention includes mandated territory (Legaue of Nations mandates) within national territory for the purposes of the convention. Unfortunately trusteeships under the United Nations Charter are a different type of legal entity and further international consideration must be given to determine the status of airspace over United Nations trusteeships, unless it be clearly set out in the terms of the trusteeship agreement.

(3) Airspace over the high seas is free to the use of all states

The basic principle of international air law is that the airspace has the same legal status as the surface of the earth beneath it Airspace over land areas, inland waters, bays, or gulfs under national sovereignty and territorial waters of any state is part of the national airspace of such state Airspace over the high seas or other parts of the earth's surface not subject to the national sovereignty of any state is free to the use of all nations. As a result freedom of the air really exists to the same extent as does true freedom of the sea. Where the rules of international maritime law and the rules of international air law differ radically is on the right of passage through territorial waters and into open ports as accorded by maritime law to foreign surface vessels, and as denied in the airspace over such territorial waters and ports to aircraft of foreign nations except with the specific permission of the state concerned This freedom of airspace over the high seas was evidenced in the report of the Aeronautical Commission at Paris referred to earlier. The freedom of the airspace over the high seas is further evidenced by the provisions of article 12 of the Chicago convention which contemplates that each state shall adopt its own measures to regulate flight in the airspace over its own territory and will undertake to keep these regulations uniform with those established under the convention, but as to the airspace over the high seas "the rules in force shall be those established under this convention." In other words, no single state has the right to legislate flight rules over the high seas, but the adoption of such rules may be accomplished by international legislation.

(4) Every sovereign state has complete control of the airspace over its territory, has the exclusive right to fly in that airspace, and may exclude all foreign aircraft or admit them on such terms as it sees fit

This means that landlocked states such as Switzerland and Bolivia may fly beyond their borders only with the consent of neighboring states. Island states such as England and Scotland combined, Australia, New Zealand, the Philippines, and Iceland, may fly out of their borders and over the high seas as and when they may desire. The United States may fly from its shores over the Atlantic, the Pacific, or the Gulf of Mexico at will, but may fly across its other borders into the airspace over Canada or Mexico only with the permission of such border states.

REGULATION OF INTERNATIONAL FLIGHT UNDER THE CHICAGO CONVENTION

Judge Manley O Hudson has stated that "the term 'international legislation' would seem to describe quite usefully both the process and the product of the conscious effort to make additions to or changes in the law of nations." (Hudson, International Legislation, I, 1919–21, p. xiii of introduction.) The Paris convention of 1919, the Habana convention of 1928, and now the Chicago convention of 1944 are typical examples of such international legislation. International flight developed too fast to provide for the gradual process of the growth of customary international law as a basis of regulation. The drafting of the Paris convention of 1919 at the end of World War I was a conscious and studied effort to provide for the regulation of flight in time of peace Such was also the Habana convention, designed to be effective in the Western Hemisphere. Both of these have now been superseded by the Chicago convention. The first two articles of this convention, as I have indicated earlier, restate prior existing international law as to the legal status of flight space. The only international legislation included in these first two articles might possibly be said to be the extension of the territory of a state to include lands under its sovereignty, protection, or mandate. These provisions might be considered international legislation. Otherwise it is simply an affirmation of a prior existing and accepted doctrine. But the balance of the convention is true international legislation. It represents a conscious effort to make additions to, or changes in the law of nations Time does not permit me to discuss more than a very few of its provisions. Some are, however, of seeming interest to the naval profession

Article 3 (state aircraft).—The convention is normally applicable to civil aircraft and not to state aircraft. All aircraft used in military, customs, and police services "shall be deemed to be state aircraft." However, the convention does provide that "no state aircraft of a contracting state shall fly over the territory of another state or land thereon without authorization by special agreement or otherwise, and in accordance with the terms thereof." This means that no aircraft used in the military services may be flown into or over the territory or territorial waters of another state without special permission having been received, even though as between the two states concerned an agreement may exist granting reciprocal flight privileges to nonmilitary aircraft.

Article 5 (nonscheduled flight)—Under this article the contracting states exchange privileges for their aircraft not engaged in scheduled services. It must be noted that this article applies only to aircraft of contracting states. This means that any state renouncing the convention is thereby released from any obligation that it may have to allow foreign aircraft to enter its territory. Had the convention intended to evidence the general freedom of flight internationally, the privilege of flight would have been made available to aircraft of all states and not to aircraft of contracting states.

Article 6 (scheduled air services).—This article provides that "no scheduled international air service may be operated over or into the territory of a contracting state except with the special permission or other authorization of that state, and in accordance with the terms of such permission or authorization." The contents of this article provide further evidence of the acceptance of the basic international air law rule cited above that every sovereign state has complete control of the airspace over its territory and may exclude all foreign aircraft or admit them on such terms as it sees fit. It is because of the existence of this article that the states which are parties to the Chicago convention have negotiated various bilateral agreements and have sought, as yet without result, to agree on a general multilateral agreement for the exchange of flight privileges in international commercial air transport.

Article 8 (pilotless aircraft).—Article 8 provides that "no aircraft capable of being flown without a pilot shall be flown without a pilot over the territory of a contracting state without special authorization by that state and in accordance with the terms of such authorization." It will be noted that this important paragraph makes no mention of airspace It is a definite agreement as between the contracting parties that no type of aircraft flown without a pilot may be flown over the territory of such contracting states (at no matter what height) without special authorization The presence of this article in the convention may be considered together with the failure of articles 5 and 6 to mention airspace, as evidence only of a treaty agreement between the parties to the convention regarding the use of all flight space over their respective territories It does not appear to constitute a statement of a general rule of international law as to limitations in the use by all states, irrespective of the convention, of that part of flight-space above the airspace

Article 9 (*prohibited areas*).—This article provides that "each contracting state may, for reasons of military necessity or public safety, restrict or prohibit uniformly the aircraft of other states from flying over certain areas of its territory, provided that no distinction in this respect is made between the aircraft of the state whose territory is involved, engaged in international scheduled airline services, and the aircraft of the other contracting states likewise engaged." This provision was inserted in the convention so that, as between contracting states, military or other prohibited areas could not be used as a screen for discrimination between the international services of the states concerned and other states. It is not considered that anything in this article limits the right of states to set up prohibited areas for any reason that they may desire as against noncontracting states.

Article 12 (*rules of the air*).—Under this article each contracting State undertakes to keep its own regulations as to use of airspace over its territory "uniform, to the greatest possible extent, with those established from time to time under this convention." This provision constitutes the greatest difference between the Paris Convention of 1919 and the Chicago Convention of 1944. Under the former convention, various annexes, including those providing for rules of the air, could be adopted and made part of the convention without reference back to member states for ratification. Doubt always existed whether the United States and certain other American Republics could legally accept the Paris Convention for this reason, as in the United States and certain other American Republics having similar constitutional provisions, every treaty amendment requires constitutional reratification. The Chicago Convention is so drawn that the rules of the air and other flight regulations, when adopted by the International Civil Aviation Organization, are not ipso facto enforcible as to flight in national airspace, but come into force as to such flight only when adopted into the local regulations by the several states. But, as indicated earlier, this same article 12 provides that over the high seas the rules in force shall be those established by the International Civil Aviation Organization under the convention. Such rules do not require separate state ratification.

Articles 17–21 (*Nationality*).—These articles provide that aircraft shall have the nationality of the State in which they are registered, that an aircraft cannot be validly registered in more than one state, and that aircraft engaged in international air navigation shall bear appropriate nationality and registration marks. Nothing in these articles or elsewhere in the convention legislates on the difficult and doubtful point as to whether this "nationality" means more than similar international regulations requiring automobiles to carry nationality license marks for identification. The convention does not settle the question as to whether aircraft have the somewhat fictional character of being part of the territory of the state of its flag, which a merchant ship supposedly possesses, when proceeding abroad. This entire question is still open and will need further international legislation.

The foregoing provisions of the Chicago Convention appear to be especially pertinent in a general discussion of international air law. My failure to mention other specific provisions of the convention does not mean that the remaining parts of the convention are unimportant or need not be carefully considered by anyone dealing with international aviation problems.

REGULATION OF INTERNATIONAL FLIGHT IN TIME OF WAR

Dealing with international air law in time of peace is comparatively simple. Most of its salient provisions are evidenced by international conventions or can be easily ascertained along the lines of the earlier parts of this discussion, but as to the rules applicable in time of war, the situation is quite different.

Whenever a rule is stated as being applicable to the relations between States in time of war and involving the use of any kind of flight, I would suggest that this rule be subjected to the following test: Is it of such character you could prove its existence and rely upon it in a case before the World Court? You will doubtless recall that the Statute of the International Court of Justice (the World Court), as established by the Charter of the United Nations, definitely instructs the Court as to the sources from which it may determine the existence of international law. Article 38 of the Statute of the Court provides as follows:

"1. The Court, whose function is to decide in accordance with international law such disputes as are submitted to it, shall apply:

(*a*) international conventions, whether general or particular establishing rules expressly recognized by the contesting states:

(*b*) international custom, as evidence of a general practice accepted as law:
(*c*) the general principles of law recognized by civilized nations:
(*d*) subject to the provisions of article 59, judicial decisions and the teachings of the most highly qualified publicists of the various nations, as subsidiary means for the determination of rules of law."

Article 59 referred to says that the decision of the Court has no binding force except between the parties and in respect to that particular case.

In applying this statute it is suggested that you also recall that the Permanent Court of International Justice in deciding the celebrated case of the S. S. Lotus (2 Hudson, World Court Reports (1935), p. 20) said, with reference to custom or usages as a source of international law, that "the rules of law binding upon the States therefore emanate from their own free will as expressed * * * by usages generally accepted as expressing principles of law and established in order to regulate the relations between these coexisting independent communities or with a view to the achievement of common aims." It is also well to recall, when considering the "teachings of the most highly qualified publicists" that the Supreme Court of the United States in the case of *The Paquete Havana* (175 U. S. 677) warned that the works of jurists and commentators on the subject of international law "are resorted to by judicial tribunals not for the speculations of their authors concerning what the law ought to be, but for trustworthy evidence of what the law really is."

Considering first the applicability of international conventions, the Chicago Convention definitely authorizes contracting states, in article 89, to disregard its provisions in time of war. This article states that "in case of war the provisions of this convention shall not affect the freedom of action of any of the contracting states affected, whether as belligerents or as neutrals." In my judgment this will authorize any contracting state to disregard all of the legislative provisions of the convention in time of war. I do not think that it changes in the slightest the basic international air law rules as to airspace sovereignty, which, as I have sought to demonstrate earlier, existed long prior to the convention. The fact is that no presently existing convention can be relied on as a source of international air law applicable to war conditions This was recognized by the statement in International Law Situations of the Naval War College for 1938 (p. 38) that there were at that time "no binding rules of international law in regard to the conduct of hostilities in the air or in regard to neutral and belligerent rights in the air, * * * that most of the conceptions and many of the rules of maritime law will be carried over into rules for the air" and that "international agreement on the application of these rights is desperately needed." I must express the gravest doubt as to whether anything developed during World War II which demonstrates that the various maritime rules applicable to sea warfare have been in fact accepted by analogy as applicable to air warfare

You are doubtless familiar with the fact that after World War I an effort was made at the Washington Disarmament Conference in 1921–22 to agree on limitations of air armaments This was found inpractical. Arrangements were then made for a meeting of experts to be held to draft rules of air warfare which might be internationally adopted. A Commission of Jurists met at The Hague from December 1922 to February 1923 and produced what are now known as "The Hague Air Rules of 1923." They warrant careful study. But it must be understood that they never became effective. They may be considered as nothing more than the statement of a group of able international lawyers covering in part what they considered the law to be, and in part what they considered the law ought to be. Undoubtedly they have influenced government departments to some extent, but they can only be used, in determining what is the international law of the air, by testing their contents against accepted customary usages.

In 1939 the Harvard Research in International Law published its able and noteworthy study of "Rights and Duties of Neutral States in Naval and Aerial War." This included a draft convention covering a wide range of subjects, among them Aerial War In the notes to this draft convention will be found the following pertinent comment (p. 757): "It must be recognized that the development of aerial warfare and of commercial transport are of such relatively recent origin that it has produced no extensive practice of states sufficient to constitute rules of customary international law." The draft convention proposed by the Harvard Research covered parts of the subject-matter of The Hague rules of 1923, but did not include provisions as to the actual conduct of hostilities.

With this background and the resulting entire lack of certainty as to the rules of international air law in time of war, it is useful to examine a few specific situations within the limited time available.

Air bombardment.—During World War II Marshal of the RAF Sir Arthur Harris, who was Air Officer Commanding-in-Chief, Bomber Command, RAF, from February 1942 until the war ended, must have had responsibility for making grave decisions as to the conduct of air bombardment over enemy territory and over enemy-occupied territory. He must have had available adequate advice as to the existence of rules of international law covering the important military operations under his command. In publishing an account of these operations after the end of the war, he has given this unequivocal opinion: "International law can always be argued pro and con, but in this matter of the use of aircraft in war there is, it so happens, no international law at all." (Bomber Offensive, London, Collins, 1947, p. 177.) Such a statement coming from such an authoritative source cannot be disregarded.

The history of air bombardment during World War II is well known. Before the outbreak of the war and after both Germany and Japan had left the League of Nations, the Assembly of the League, considering the necessity for regulation of air bombardment, adopted the following resolution which has not had the consideration that it warrants:

"The Assembly * * *

"Recognizes the following principles as a necessary basis for any subsequent regulations;

"(1) The intentional bombing of civilian population is illegal.

"(2) Objectives aimed at from the air must be legitimate military objectives and must be identifiable.

"(3) Any attack on legitimate military objectives must be carried out in such a way that civilian populations in the neighbourhood are not bombed through negligence." (League of Nations Paper A 69, 1938, IX. September 28, 1938. Protection of Civilian Populations Against Air Bombardment.)

The difficulty with the entire problem of determining the international law of air bombardment arises from the lack of an accepted definition of what constitutes "a legitimate military objective" and what constitutes "civilian population." On the outbreak of World War II, President Roosevelt appealed to the belligerents urging that civilian populations be not bombarded from the air. Great Britain and France replied that they had instructed their commanders prohibiting bombardment from air or sea or by artillery on land "of any except strictly military objectives in the narrowest sense of the word." Hitler also indicated his agreement. But as the war progressed concepts were continually expanded and every nation originally engaged or which later became involved was faced with the practical necessities of war as it is now conducted, and found it necessary to consider as military objectives entire areas which contained industries, transportation facilities, or other parts of the complicated national machinery which is used behind the lines in modern warfare. Finally the climax of atomic bombing over Japan brought the world face to face with the question: Is there any international law to determine with exactness the definition of bombing objectives? At the last annual meeting of the American Society of International Law held in Washington, April 22–24, 1948, an Army officer present (speaking for himself and not for the Judge Advocate General's office to which he was attached) made "a plea for some constructive thought concerning the development of the international law of war." He insisted that "today there is absolutely no regulation concerning the use of aircraft in war," and that "if it is the practice of nations alone that makes international law, then we must accept the fact that the practice of both sides during this last war has made the use of aircraft for the indiscriminate bombardment of cities a part of international law." He urged that "we must attempt to draft and have accepted reciprocal rules of aerial warfare under which the next conflict can be fought," and that "to be effective, they must be rules which will grant reciprocal protection to both sides." With this position I agree. In the absence of the adoption of such a convention and faced with what appears to be lack of acceptance of clearly defined customary rules covering air bombardment, I am not clear as to whether there is any international law on the subject at the present time. Perhaps when we have had an opportunity to examine the records and findings of the various war crime courts and tribunals sitting in Germany and Japan, we may find that rules can be determined under "the general principles of law recognized by civilized nations" accepted as a source of international law to be applied by the World Court. But what those rules are I am unable to state today.

RELATIONS BETWEEN BELLIGERENTS AND NEUTRALS

One of the few groups of rules which can be considered as reasonably well established in international air law covers the right of neutrals to close their air boundaries in time of war and prohibits belligerents from engaging in acts of war over neutral territory. These rules arise from the basic considerations of airspace sovereignty already stated. In both World War I and World War II neutral states repeatedly forced down and interned belligerent military aircraft entering their airspace. During World War II the United States paid a very considerable indemnity to Switzerland on account of damage to property and loss of life of certain Swiss citizens occurring as the result of bombs being dropped by American aircraft on Swiss territory through error The Harvard Research has stated in its proposed articles 95, 96, and 97 of the draft convention, published in 1939, the following rules:

"*Article 95.*—A neutral state shall use the means at its disposal:

"(*a*) to prevent belligerent military aircraft from entering its territory; and

"(*b*) to compel them to alight if they have entered, and

"(*c*) to intern them after they have alighted, whether the landing be voluntary or forced, together with persons and property on board.

"*Article 96.*—The neutrality of a state is not violated by the passage through its territory of public nonmilitary or unarmed belligerent private aircraft.

"*Article 97.*—The requirements of neutrality do not in general necessitate the closing of neutral aerial frontiers against the passage of aircraft of other neutral states."

It will be noted that article 95 puts a positive duty on neutral states to use the means at their disposal to prohibit the entry of military aircraft and to compel them to alight. With this possible exception I believe that these rules state customary international law as evidenced by actual conduct of neutral and belligerent states during World War I and World War II. Certainly neutral states have the right to take the several actions mentioned in article 95, and I think that the evidence would be sufficient before an arbitral tribunal to sustain the actual duty to do so as outlined in the Harvard Research Article 95.

Whether it is possible to go further than this in stating the existence of definitely accepted rules applicable to relationships between belligerents and neutrals arising from air war is not at all clear. It has been repeatedly stated, for example, that the right of visit and search exists and that a belligerent aircraft may exercise this right of visit and search as against neutral aircraft. The Harvard Research Article 111 states that "belligerent aircraft may order such neutral aircraft to alight for visit and search in a locality reasonably safe and accessible" and that "refusal after warning to obey such orders to alight or to proceed to such a locality for examination, exposes an aircraft to the risk of being fired upon." Those of us who have had something to do with the operation of air transport services realize the practical difficulties in any such procedure. It is impossible to land an aircraft on the high seas with any degree of safety, even in the case of seaplanes, nor is it usually possible to divert an air transport with any degree of safety because of the closely calculated amount of fuel the aircraft carries to reach a scheduled destination. Actually I have been able to find no case in which this alleged right of visit and search has been exercised during either World War. Quite recently I had occasion to inquire about this matter. Dr J. M. Spaight, author of the authoritative Air Power and War Rights, advises me that he also knows of no instance of the exercise of the right of visit and search of aircraft by aircraft during World War II. In the absence of custom to establish the right, and to provide for the procedure of making it effective, and in the absence of any international convention or any court decisions on the subject, we are forced to the decision that the entire doctrine of visit and search of aircraft by aircraft depends on the perhaps justified views of qualified writers as to what international air law should be, leaving in doubt whether any such law on the subject actually exists.

The difficulties involved in the operation of air transport services by a neutral state to and from a belligerent state are evidenced by the problems presented to the Swedish airlines during the last war Traffic was inaugurated in February 1942 between Stockholm and Scotland after negotiations between the British and Swedish Governments. The German Government was not involved. Flights were operated at night over the North Sea when weather conditions were believed suitable—that is, when there were clouds and no moon. Aircraft were painted orange with Swedish markings but carried no lights. Radio communication was maintained only while the aircraft were over Swedish or British territory. One

night toward the end of August 1943 a plane returning from Scotland to Stockholm disappeared over the North Sea and traffic was suspended. It was believed that the plane was shot down by a German fighter plane, but no proof was available. A week after this accident traffic was resumed and toward the end of October a second plane crashed on the Swedish coast on its return trip from Scotland. On this occasion 1 crew member and 1 passenger survived and it was definitely proven that the plane had been shot down by a German fighter. The Swedish Government protested to German authorities who refused to pay any indemnity, contending that the German fighter had mistaken the aircraft for an Allied bomber. Traffic was again suspended. Thereafter, pursuant to negotiations by the Swedish authorities with both Allied and German authorities, the safe conduct traffic from Stockholm to Scotland via Norway was organized The planes carried full illumination, radio communication was maintained with German stations over Norway and British stations when approaching and leaving Scotland. After 12 trips, the British authorities canceled the arrangement. Later it was resumed on the original basis—that is, high altitude flights of unlighted planes at irregular intervals

This illustrates the lack of any accepted rules as to the maintenance of mutual commercial traffic between neutral and belligerent countries. It was my judgment during World War II, when I had some responsibility in the matter, and it is my judgment today that such neutral commercial aircraft engaging in transport to and from belligerent countries over routes which are in the part of the world where air hostilities may take place must accept risks of destruction in the absence of international convention to the contrary. From the belligerent point of view it must be realized that it is very difficult to distinguish between transport and bomber aircraft under bad weather conditions or during night flights Also, in the absence of some practical arrangement as to visit and search, a belligerent can prevent illicit air transport contraband operations only by shooting down neutral aircraft proceeding to and from belligerent territory in the war area. I again regret that I cannot accept the theory that the rules applicable to neutral shipping may by analogy be accepted at this time as part of international air law.

FUTURE USE OF GUIDED MISSILES ABOVE THE AIRSPACE

In closing this discussion I wish to present a problem to the Naval War College and request the assistance of the officers on duty here. Thus far I have not been able to produce a solution which satisfies me. Suppose that country A and C are at war. Their land territories do not touch at any point. A neutral country B occupies the surface territory between A and C. Let us then assume that country A starts bombarding country C with guided missiles passing through flight space over country B at an altitude which may be considered beyond the airspace and at a height where country B may find it impossible, with any devices in its possession or even in existence, to intercept such guided missiles or otherwise prevent their passage over its territory. Had the neutral rights of country B been affected?

Inherent in the answer to this problem is the basic difficulty of future international air law—to what height above the surface of the earth can the sovereignty of a state be extended. Able experts will contend that territory never exists beyond the ability of the state claiming such territory to make its laws effective and that sovereignty is the power to control. Other experts will contend that sovereignty is the right to control territory and that every state may be assumed to have sovereignty in space up to any height which any other state can reach with devices or missiles in its possession. In view of the fact that some of my scientific friends are convinced that rockets or other guided missiles may be propelled from the earth to the moon within a comparatively few years, the problem presents curious political and geographic difficulties.

High Altitude Flight and National Sovereignty

An address delivered before the Escuela Libre de Derecho, Mexico City, January 5, 1951, by John C. Cooper, Member Institute for Advanced Study (Princeton), Fellow American Academy of Arts and Sciences, Member Institute of the Aeronautical Sciences.

High altitude rocket flights have reopened an old question: How far upward in space does the territory of the state extend? This is a simple question to state, but a very difficult question to analyze, and perhaps even now an impossible question to answer. Nevertheless it must be considered.

If international relations are to be conducted in the future in anything approaching a normal manner, both the statesman and the jurist ought to know the extent to which a state has the acknowledged right to control all activity in the areas of space above its surface territory.

The territory of a state, geographically considered, is a three-dimensional region It includes an area on the surface of the earth, a sector of the earth below, and a sector of space above. Legally considered, the territory of a state may be defined as those regions in which the state is recognized by international law as having the right to exercise national sovereignty to the exclusion of all other states. As the distinguished jurist, Max Huber, said in his opinion in the island of Palmas arbitration between the United States of America and the Netherlands: "Sovereignty in the relations between states signifies independence. Independence in regard to a portion of the globe is the right to exercise therein to the exclusion of any other state the functions of a state * * * territorial sovereignty * * * involves the exclusive right to display the activities of a state" Among these territorial functions are included the right of a state to determine the extent to which it will control and police human activity within its territory

The legal concept that a state has territorial rights above the surface of the earth is far older than the discovery of the art of human flight. Rome did not hesitate to control the use of space whenever deemed necessary to protect public or private rights on the surface of the earth. The airspace over public highways and over sacred ground was kept open by law. The Roman emperors limited the height to which buildings could be erected. Private rights in space above the landowner's property on the surface were carefully protected. The Roman state made its laws as effective above the surface of the earth as it did on the surface. The great jurists of a much later era fully recognized the existence of state sovereignty in space. Pufendorf, for example, in the latter part of the 17th century remarked that "since man has been denied the ability to be in the air to the extent that he rest in it alone, and be separated from the earth, he has been unable to exercise sovereignty over the air except insofar as men standing upon the earth can reach it." To Pufendorf sovereignty in space was thus limited by the ability for effective control, and not otherwise.

With the discovery of the balloon in 1783 and the gradual development of the art of man-controlled flight culminating with the Wright brothers in 1903, man found a way "to be in the air to the extent that he rest in it alone," and the problem of the extent of state sovereignty upward became acute In analyzing this period it must always be remembered that neither statesmen nor lawyers conceived of the possibility of man-made flight through space beyond a region where there would be sufficient gaseous air to support a flight instrumentality of the general nature of a balloon or an airplane So in 1906 when Professor Westlake, at a meeting of the Institute of International Law, first put into concrete legal statement the doctrine of state airspace sovereignty, he added that there was no limit upward of such sovereignty. Discussing the necessity for state control in the air over its territory, he said "In the air the higher one ascends, the more damage the fall of objects will cause on the earth If there exists a limit as to the sovereignty of the state over the oceanic space, none exists for the sovereignty of the state over the airspace. The right of the subjacent state remains the same whatever may be the distance" It is perfectly obvious that Westlake assumed that the state had territorial rights in space as high as flight could exist, but at the same time he assumed that such flight must take place in what he termed "air space."

In 1911 the British Government prepared a draft statute to be entitled "Aerial Navigation Bill" which, in its preamble, recited that "the sovereignty and rightful jurisdiction of His Majesty extends, and has always extended, over the air superincumbent on all parts of His Majesty's dominions and the territorial waters adjacent thereto" Again it was assumed that if the state had sovereignty "over the air," it had the right to regulate all flight over its lands and waters.

Whether the term "air" or the term "airspace" was used, the basic idea was the same In the first great international legislative enactment of the fundamental principles of air law, the Paris Convention of 1919, article 1 stated that "The High Contracting Parties recognize that every Power has complete and exclusive sovereignty over the airspace above its territory" The convention then proceeded to the regulation of the use of "aircraft." In the annex to the convention, adopted shortly after it came into effect, aircraft were defined as comprising "all machines which can derive support in the atmosphere from reactions of the air."

The Paris Convention was a statement of long existing and fully recognized state sovereignty over a region called "airspace," but otherwise undefined, in which "aircraft" might operate But the Paris Convention is not to be construed as meaning that in international law states have territorial rights only in this airspace.

The airspace was accepted as part of state territory but no international determination was made as to the regions of space above. The same argument can probably be made with reference to the statutes of various states not parties to the Paris Convention which asserted sovereignty over the "airspace."

It might be argued that the Paris Convention, and certain other conventions, asserted state sovereignty in the earth's "atmosphere" beyond the regions where sufficient air exists to support the flight of aircraft as defined in the Paris Convention. Both the French and Italian versions of the Paris Convention use language in article 1 which literally translated into English means "atmospheric space" (French: espace atmospherique, Italian: spazio atmosferico). My own view has always been that these terms were intended to mean exactly what the English version meant, namely, the region of space where the "air" was present in, it must be assumed, sufficient quantities to support flight in the balloon or airplanes which were regulated by the convention. This argument is supported by the fact that the Madrid Convention of 1926, signed by Spain and various Latin American countries, referred in article 1 to sovereignty over "atmospheric space" (espacio atmosferico); while in the Habana Convention of 1928, signed by many of the same states, state sovereignty is recognized over the "airspace" (official Spanish text: "espacio aereo"). Although, as will be indicated hereafter, the earth's atmosphere from the purely scientific point of view extends much further above the surface of the earth than does the region in which "air" is present in sufficient quantities to maintain aircraft flight, it would seem that in the Paris, Madrid, and Habana Conventions the terms "airspace" and "atmospheric space" must be considered as synonymous, constituting legally a recognition that every state has territorial rights at least through these regions where sufficient gaseous air is found to support such flight.

This view is further borne out by the fact that the Chicago Convention of 1944, now in force, states in article 1 that "The contracting States recognize that every State has complete and exclusive sovereignty over the airspace above its territory." While the convention recites that French and Spanish texts were to be drawn up and opened for signature, this was apparently never done and the English text is still the only text which was officially signed. In the French translation of the convention which is ordinarily used, so I am advised, the English word "airspace" has been translated as "espace atmospherique," while in the Spanish translation distributed by the International Civil Aviation Organization, it has been translated as "espacio aereo."

It may, therefore, be said that international law now answers the question "How far upward in space does the territory of the State extend?" as follows: The territory of the state extends upward at least as far above the surface as to include a region which can be roughly defined as "airspace." An international law contains no presently accepted rule covering the question as to whether usable space above and beyond the "airspace" is or is not part of the territory of the state below.

It is at this point that high altitude rocket flights open unsolved legal and political problems. Just how high such flights have been made I do not know. But as long ago as the spring of 1949 it was disclosed in the public press that a 2-stage rocket had reached a height of at least 250 miles (400 kilometers) above the surface of the earth. This rocket passed far above the region which can, under any theory, be described as "airspace." The question is: Did it pass out of the territory of the state below when it left the airspace, and reenter that territory on returning; or was it at all times within the territory of the state below?

Before even suggesting an answer it is necessary to consider very briefly certain of the scientific views now generally held as to what constitutes the earth's atmosphere. This atmosphere is usually described as constituting four gaseous layers known as the troposphere, stratosphere, ionosphere, and exosphere. The troposphere is next the earth and the exosphere is the far distant region which gradually merges into outer space. The "airspace" is part of the lower atmosphere region. The troposphere extends upward about 54,000 feet (16,200 meters) at the equator, and 28,000 feet (8,400 meters) at the poles. It contains about three-fourths in weight of the gases composing the earth's atmosphere, and is characterized by continually decreasing temperatures with increase of altitude. The stratosphere extends from the upper level of the troposphere to about 60 or 70 miles (100 or 115 kilometers) above the earth's surface. It contains slightly less than one-fourth in weight of the earth's atmosphere, is characterized by constant temperature of about 67° F. (20° C.), then decreasing again to about −28° F. (−33° C.)

The ionosphere extends from the upper levels of the stratosphere to approximately 400 miles (640 kilometers) above the surface of the earth. It is said to be

characterized by the existence of what have been termed by some authors as "free electrical discharges." The temperature is estimated to increase steadily up to approximately 4,000° F. (2,200° C.).

The exosphere is the fringe area beyond the ionosphere in which the density of the gaseous atmosphere is even less, and is supposedly characterized by a uniform temperature of approximately 4,000° F. (2,200° C.).

It will be seen from the foregoing that the rocket which reached 250 miles (400 kilometers) above the surface of the earth was high up in the ionosphere. It was far past any region that could be termed "airspace." It is generally believed that above 60 miles beyond the earth's surface (approximately 100 kilometers) what we would term as a vacuum exists and that all of the aerodynamic features of flight which result in the lift of a normal type of aircraft have disappeared. It may be recalled in this connection that no airplane has ever been flown more than approximately 60,000 feet above the surface, sounding balloons have probably reached an altitude of 120,000 feet—both of these distances being far below the theoretical absolute outside limit of what might be termed "airspace."

Scientific investigation and progress in known rocket flights have therefore demonstrated that none of the international procedure set up in the Paris and Chicago Conventions applies in a very large percentage of the region to which these rockets have already reached. Future scientific progress makes the problem even more difficult. Rockets now in use are leaving the earth's surface at speeds of at least 5,000 miles per hour (8,000 kilometers). It has been estimated that if this speed can be increased to approximately 25,000 miles per hour (40,000 kilometers) at the top of the atmosphere, the power can then be shut off and the rocket would continue moving upward indefinitely. Certain scientists believe that these speeds can be attained with fuels now available, although at very great costs; others believe that new methods of propulsion may be required. One of my friends, a well-known astronomer, has indicated to me that the point at which such a rocket would leave the earth's area of attraction and pass under the predominance of the sun would be approximately 161,000 miles (256,000 kilometers) above the earth's surface. It is well to bear that figure in mind because if we hold to the old classic legal theory, as stated by Westlake, that a state must have sovereignty as high up into space as necessary to protect itself from "falling" bodies, then perhaps the state's territory is 161,000 miles in height.

But the problem is even more complicated than as just indicated. If a rocket or other man-controlled missile can take off from the earth with a speed of approximately 17,500 miles an hour (26,400 kilometers), it will be able to proceed upward for several hundred miles and could then be deflected off of its course so as to be aimed somewhat parallel to the surface of the earth, the power could be turned off, and the rocket would continue on a course around the earth as its momentum would approximately balance the earth's attraction. It would become an artificial satellite. From the international lawyer's point of view the question then arises: Does such an artificial satellite, flying several times per day around the earth and passing far above the surface territories of many states, enter and leave the territory of each of such states when immediately above their surface boundaries? If we accept the theory that the territory of the state extends as far upward into space, even though that space be a vacuum, as required to prevent the entry of manmade activity which may result in injury to persons and property on the surface of the state, then we must assume that such a satellite is violating the sovereignty of every state below which has not consented in advance to its passage There are scientists who believe that such a satellite can and will be constructed before many years have passed.

It is obvious that it is the duty of the trained jurist to suggest an answer to these problems It may be that a new international convention is required which will include some sort of agreed international limitation on the extent to which states will engage in high altitude flight somewhat similar to article 8 of the Chicago Convention which provides that no aircraft capable of being flown without a pilot shall be flown without a pilot over the territory of a contracting state without special authorization by that state

In the absence of such a new convention, basic legal theories must be reexamined and the practical questions at issue must be understood

In the first place it is obvious that we must agree that there is an upper boundary in space to the territory of the subjacent state. Under no possible theory can it be said that a state can exercise sovereign rights in outer space beyond the region of

the earth's attraction. The arguments for state sovereignty in space have always gone back to the proposition that it is both the right and the duty of the state to protect itself and that on no other basis can such protection be considered adequate except that it have the right to control, as part of its territory, those regions above it which, if used by other states, may bring damage and loss to persons and property on the state below. Carrying this old rule to its extreme, the outer boundary of the state cannot be further than the point where the earth's attraction will govern the movement of an object in space so that such object will "fall" onto the earth.

On the other hand, this boundary cannot be lower than the upper limit of the airspace. The rule of international law—that the territory of the subjacent state includes at least the region above it known as airspace—need not be challenged. In other words, it would appear that the upper boundary of the state's territory lies at a point between the upper limit of the airspace and the upper limit of the earth's attraction. Somewhere in this vast intervening region the rights of the state below cease to exist as against other states.

Certain jurists have insisted that the territory of a state is limited by the ability of that state to make its law effective. This is a harsh rule when applied to sovereignty in space The richest and most powerful states now have means through high altitude rockets to control more or less effectively the airspace over their surface territories. But the weaker states have no such power. Can we be said to live in such a world where the physical power at any one time of any particular state determines its international right to consider the region above its surface territories as part of its national territory? I may say here that my own belief is and has always been that if the rule of effectiveness is to be applied to determine the limit of state territory in space, then the rule should be that every state, no matter how small or how weak, as a state or equal sovereignty with every other state, has and should be admitted to have territorial rights upward above its surface territories as high as the rights of every other state no matter how powerful

Perhaps the rule should be, in the absence of international agreement, that the territory of every state extends upward as far into space as it is physically and scientifically possible for any one state to control the regions of space directly above it. In considering the possibility of adopting such a rule as this as part of international law, its limitations must be understood The enormous distances involved must not be forgotten. Assuming that a state has acquired the use of a rocket that will leave the earth at the suggested speed of 25,000 miles per hour, it must be remembered that as it moves upward it will be continually slowed by the earth's pull. Therefore it would take a rocket traveling at even this tremendous velocity well over 6 hours to reach the theoretical distance of 161,000 miles beyond the earth's surface, at which point it enters into the area where the sun's attraction begins to predominate.

By the time that the rocket reached this far-distant region, for the purpose of policing or controlling its use by other states, the rocket may have itself passed through the theoretical territory of several states. It must be recalled that the earth itself is rotating. If this rocket is driven directly upward, it may not be directly over the territory of the state which fired it for a very long period. Any theoretical possibility of a state controlling far-distant regions in space is absolutely out of the question. I am convinced that we must abandon the theory that the state has the right to claim territory out into space as far as the earth's attraction extends, and that we must admit some such reasonable rules as I have suggested above—namely, that at any particular time the territory of each state extends upward into space as far as then scientific progress of any state in the international community permits such state to control space above it.

Frankly, this is not put forward as a final solution. It is realized that it leaves open such vital questions as to what extent of control is contemplated. It also leaves open the question of by what means an international determination will be made of the ability of the most powerful State to extend its control into outer space. I could argue at forceful and great length against the solution suggested. In its favor I can only say that it is worthy of consideration; that it provides the basis for a fairly livable world in which the weak State is not at the mercy of the strong. The mere suggestion of the rule, above all else, shows the gravity of the problem and the need for an answer.

For much of the data as to the scientific characteristics of the upper atmosphere, the author is greatly indebted to the article and chart entitled "The Earth's Atmosphere," by Howard E. Roberts, Aeronautical Engineering Review, vol. 8, October 1949, pp. 18–31.

Legal Problems of Upper Space

By John Cobb Cooper [1]

[Reprinted from the Proceedings of the American Society of International Law, 1956, pp. 85–93]

Today neither lawyers not governments are prepared to state the legal flight rules applicable to presently operating rockets and planned satellites. For the second time in the present century science and engineers have far outstripped the law. Such delay may be normal where legal rules must depend on known and accepted factual situations, but the gap between technological and legal progress must never be permitted to become too wide.

The present problem confronting us is this: Flight instrumentalities, such as rockets, satellites, and other spacecraft do not fall within existing national or international regulatory provisions. Nor is there any agreement as to what, if any, national or international regulation is applicable to space above the atmosphere where such rockets and satellites will normally be used. This existing legal hiatus can lead to grave international misunderstanding if permitted to continue too long

Flight technology first outdistanced the law in the early years of the present century when it became necessary to determine whether aircraft and balloons were vehicles like automobiles or whether they had nationality like ships; also, whether the atmosphere space in which they operated was or was not part of the territory of the subjacent state The manner in which these questions were settled reveals the extent of the dangerous legal hiatus which now confronts us.

Flight became a factor in international affairs when it could be controlled by man. The airship flights of von Zeppelin between 1900 and 1902, and the airplane flight of the Wright brothers in 1903, were the real beginning. But governments were slow to fix the legal rules, and jurists were not in agreement. In 1906, in the much-discussed debates in the Institute of International Law, Fauchille urged freedom of flight and Westlake insisted upon national airspace sovereignty. But the importance of this discussion has, in my judgment, been exaggerated. It had little, if any, influence on the subsequent activities of states. Fauchille ignored the fact that distinguished jurists had long insisted that territory must be three dimensional. Westlake, while supporting sovereignty, appeared to believe that such sovereignty should be subject to an international right of innocent passage through the airspace, although no state ever accepted this dictum in practice

Governments did not become really concerned until France, in 1908 and 1909, took alarm at the number of German balloons which were drifting into France, many apparently manned by military personnel, and called the celebrated 1910 International Air Navigation Conference. This met in Paris to consider the possible regulations of international flight. The United States was not invited, as it was considered too far away to be affected. On more than one occasion I have stated my view that the proceedings of this 1910 Paris Conference, with its almost completed draft convention, indicated general agreement that each state had full sovereignty in then usable space over its national lands and waters, that no general right of international transit existed for aircraft of other states in the absence of international convention, and that the only practical legal method of regulating international flight was by agreement which would provide for the grant of privileges of flight through such national space.

By legislative acts and diplomatic conduct in the intervening years between the 1910 Conference and the outbreak of World War I, Europe indicated acceptance of these principles Events at the outbreak of World War I and during that war, as well as the preparation and signature of the Paris Convention of 1919, gave further evidence of the validity of the principle of absolute sovereignty of the subjacent state over the "airspace," and also of the fact that aircraft have nationality.

The Paris 1919 Convention was signed and ratified in French and Italian as well as in English The words "air space" appear in the French version as "espace atmosphérique" and in the Italian as "spazio atmosferico." It seems apparent from this that the words "air space" in the English version meant, without question, "atmospheric space."

In many articles of the convention, the flight instrumentalities to be regulated are described as "aircraft," and their nationality is recognized. Under the system

[1] Princeton, N J, Professor, Institute of International Air Law, McGill University.

of the Paris Convention, its subsequently adopted annexes became part of the convention itself In these annexes an "aircraft" is defined as follows: "The word 'aircraft' shall comprise all machines which can derive support in the atmosphere from reactions of the air." In annex A various classes of "aircraft" included balloons, airships, landplanes, seaplanes, and helicopters

Taking together the assertion of state sovereignty in article I, with this definition of "aircraft," it may be said that the Paris Convention declared that each state was sovereign in those areas of space where sufficient gaseous atmosphere existed to lift and support balloons, airships, and airplanes, as well as other types of flight instrumentalities which could "derive support in the atmosphere from reactions of the air " Man had not yet conceived the possibility of any other type of flight instrumentality, nor had he had occasion to regulate areas of space other than those used by "aircraft."

In 1926, by the adoption of the Air Commerce Act, the United States (which signed but did not ratify the Paris Convention) declared itself to possess complete and exclusive national sovereignty in the airspace over the United States, and defined aircraft to mean "any contrivance now known or hereafter invented, used or designed for navigation or flight in the air " These rules were carried forward in the Civil Aeronautics Act of 1938, and are still part of our law. It is conceivable that this definition of aircraft is broader than the Paris definition, as it seems to include flight instrumentalities used for flight in the air even though not supported thereby.

The Chicago Convention of 1944, to which most of the states engaged in international aviation are parties, except the U. S. S. R., restated in article I the provisions of the Paris Convention as to airspace sovereignty in this manner: "The contracting states recognize that every state has complete and exclusive sovereignty of the airspace above its territory." Again, as in the Paris Convention, this is a statement of customary international law and not an exchange of privileges between the states concerned. Also, the Chicago Convention deals with the regulation of "aircraft" which are given the attribute of nationality. But neither "airspace" nor "aircraft" is defined.

Under the Chicago Convention the technical standards, called annexes, do not become parts of the convention. They are prepared by the International Civil Aviation Organization, and are then submitted to the member states for acceptance. Any state finding it impractical to comply in all respects with such standards must so advise the International Civil Aviation Organization.

During the Chicago Conference, the United States submitted suggestions for future annexes, including the definition of aircraft similar to that in the Air Commerce Act of 1926 as stated above. But the Chicago Conference inserted in the tentative annexes the definition of aircraft as it had already existed in its narrower form in the Paris Convention annex. Subsequently, the International Civil Aviation Organization, when formally adopting the present annex 7 dealing with aircraft nationality and registration marks, defined aircraft as "any machine that can derive support in the atmosphere from the reactions of the air." This is almost exactly the Paris definition adopted many years earlier. In the same annex, the term "aircraft" is stated to include balloons, airships, airplanes, and helicopters, and other similar instrumentalities requiring support in the atmosphere from reactions of the air in order to maintain flight.

When this annex was submitted to the member states of the International Civil Aviation Organization, no objection was apparently raised by the United States or any other member state, and it may therefore be that this is the definition which the United States must apply in international use rather than its own definition. This, however, is a problem which has not yet arisen, but which may become acute if a type of flight instrumentality is launched by the United States, which is covered by our own definition of "aircraft," but is not included in the international definition adopted pursuant to the Chicago Convention.

From the foregoing the following appears to be the present legal situation:

(*a*) Both the Paris and Chicago conventions have dealt only with those flight instrumentalities which derive support in the atmosphere from reactions of the air, such as the balloon or airplane, and have not dealt with such instrumentalities as rockets, satellites, and other space craft which are designed to move through space without atmospheric support.

(*b*) The Chicago Convention contains no definition of "airspace" but it may well be argued that, as it was adapted from the Paris Convention, it deals with no areas of space other than those parts of the atmosphere where the gaseous air is sufficiently dense to support balloons and airplanes. The highest flight by any un-

manned balloon up to the present time is 140,000 feet, by a manned balloon 72,395 feet, and the highest airplane flight is 90,000 feet.

(c) Nothing in the Chicago Convention precludes the possibility of state sovereignty being extended by international agreement, or by unilateral force, above the areas in which the airplane and balloon can be used, but there is certainly no basis on which any customary international law can as yet be considered applicable to such higher areas.

(d) Airspace over the high seas is now free for use by all.

The present technical situation is also of major importance. Basing my information solely upon public disclosure in the press and the current literature, I would invite your attention to the following:

(a) Rockets of the so-called V–2 type, as used in the German attacks on London, are understood to have been driven to a height of about 114 miles. An American rocket, which consisted of a V–2 plus an additional rocket stage, has been publicly stated to have reached an altitude of about 250 miles.

(b) It now appears that there is an area between the highest possible balloon flight—let us say, 30 miles above the surface of the earth—and 200 to 300 miles above the surface of the earth, in which continuous or extended satellite flights may be extremely difficult due to the presence of sufficient atmosphere to create serious "drag" or heating.

(c) In other words, it is now suggested that the future satellite flight will be most practical for long distances only if conducted not less than 200 or 300 miles above the surface of the earth.

In July, 1955, the United States announced that it would support a series of satellite flights as part of the wide scientific investigation of the 1957–58 International Geophysical Year. Some of the details of the proposed flights have now been disclosed. It is planned to drive a three-stage rocket at least 200 miles above the surface of the earth, carrying in its nose the "satellite," which will be a round object about the size of a basketball. The directions of the various stages of the rocket will be so changed that when the satellite is discharged and starts on its free orbit it should be approximately parallel to the surface of the earth. Based on the much-discussed principle that if the speed of the rocket at that point is sufficient to counterbalance the attraction of the earth, the satellite should continue on an orbit around the earth for several days or even for several weeks, the time being dependent, among other things, on the amount of atmospheric "drag." The satellite will carry in its small bulk an amazing collection of instruments for obtaining information deemed by the scientists to be of the greatest possible future value. The International Geophysical Year, of which this satellite program is part, is directed by committees made up of scientists of many different nations. But the satellite itself will be launched by the United States Government.

Two authorities have already dealt with the legal problems of this flight. Mr. Andrew G. Haley, general counsel of the American Rocket Society, presented a paper at the annual meeting of that society in November, 1955, in which he seemed to suggest that the areas of space above the atmosphere to be used by the satellite might be subject to some sovereign control of the subjacent states, but that failure of any state to object to the International Geophysical Year satellite program at the time of its announcement was all that was required in order to make the completion of the program possible. He added that "The scientists have benefited mankind as a whole in a field where the lawyers might well have failed."

Quite a different thesis has been put forward by Mr. C. Wilfred Jenks, an associate of the Institute of International Law.[2] In his article Mr. Jenks noted the announcement by the White House of a satellite program "to circle the earth in 90 minutes at a height of 300 miles." His legal position is, apparently, that space beyond the atmosphere of the earth is and must always be incapable of appropriation by the projection into such space of any particular sovereignty based on a fraction of the earth's surface. He argues that the acceptance of such complete international freedom in these areas of space is required by astronomical and physical facts, and he contends that the only activities "within the atmosphere of the earth would appear to be susceptible of the degree of control similar in general nature to that which can be exercised in territorial waters or over a wider maritime frontier belt." It would therefore appear that Mr. Jenks denies the existence or possibility of national sovereignty in areas of space beyond the atmosphere—say from 300 miles above the earth's surface upward. He continues:

[2] "International Law and Activities in Space," 5 International and Comparative Law Quarterly 99–114 (January 1956).

"It would seem important to accept this principle fully from the earliest stages of the exploitation and exploration of space, and it is of interest that the United States plan for launching space satellites appears to be based upon it. There is no indication in the United States plan that it is proposed to negotiate passage agreements with the subjacent sovereignties. Moreover, such rights cannot be claimed under the International Civil Aviation Convention, since even assuming the Convention to be applicable beyond the atmosphere and disregarding the fact that certain states, including the U. S. S. R, are not parties to it, the Convention provides that pilotless aircraft will not be flown over the territory of contracting states without special authorization."

The statements by Mr. Haley and Mr. Jenks point up the importance of the problem to be considered—namely, What is the legal status of the space beyond the atmosphere where rockets and satellites can be operated without undue atmospheric interference?

A subsidiary question involves the status of the intermediate area between the upper level of the atmosphere used by aircraft and the lowest height at which a rocket or satellite may freely be operated. I am not sure that we yet have the scientific data necessary to determine the extent to which rockets or satellites may safely use this intermediate area. At least I do not feel that sufficient data is publicly available.

Five years ago, in what may have been the earliest present-day discussion of the question of the legal status of space at high altitudes,[3] I suggested that the time had come when "we must agree that there is an upper boundary in space to the territory of the subjacent state," and I said:

"Certain jurists have insisted that the territory of a state is limited by the ability of that state to make its law effective. This is a harsh rule when applied to sovereignty in space. The richest and most powerful states now have means through high altitude rockets to control more or less effectively the "airspace" over their surface territories. But the weaker states have no such power. Can we be said to live in such a world where the physical power at any one time of any particular state determines its international right to consider the region above its surface territories as part of its national territory? I may say here that my own belief is and has always been that if the rule of effectiveness is to be applied to determine the limit of state territory in space, then the rule should be that every state, no matter how small or how weak, as a state of equal sovereignty with every other state, has and should be admitted to have territorial rights upward above its surface territories as high as the rights of every other state no matter how powerful."

At the same time I indicated that this left open such questions as the extent of contemplated control, and the means by which an international determination could be made of the ability of the most powerful state to extend its control into outer space. Long and careful consideration during the past five years has convinced me of the existence of almost insuperable difficulties in applying the rule which I then suggested. The only practical way to solve the questions as to the legal status of areas above those covered by a strict construction of article I of the Chicago Convention will be the adoption of some form of international agreement.

Such a new convention might include these solutions:

(*a*) Reaffirm article I of the Chicago Convention, giving the subjacent state full sovereignty in the areas of atmospheric space above it, up to the height where "aircraft" as now defined, may be operated, such areas to be designated "territorial space."

(*b*) Extend the sovereignty of the subjacent state upward to 300 miles above the earth's surface, designating this second area as "contiguous space," and provide for a right of transit through this zone for all non-military flight instrumentalities when ascending or descending.

(*c*) Accept the principle that all space above "contiguous space" is free for the passage of all instrumentalities.

These solutions would aid future peaceful use of rockets and satellites and would seem to provide reasonable security for the subjacent state. At the same time, the territory of the state would be extended upward even beyond the areas in which it might make its normal laws effective. For I venture to suggest that, due in part to the physical problems involved, in part to the enormous speeds of the flight instrumentalities concerned, as well as many other difficulties, it will

[3] "High Altitude Flight and National Sovereignty," 4 International and Comparative Law Quarterly 411-418 (1951).

be most unlikely that any state can make its normal day-by-day laws effective very high in space I do not deny the possibility that with modern weapons, such as guided missiles, a state may exercise military command quite high into space, provided it is certain that its activities are within the areas which are really above its own territory But I must differentiate between such military control as may be involved in shooting down an intruder, and the normal civil control that a state must have day by day to enforce in its territory the peacetime laws under which men live together.

These ideas are put forward only as suggestions. The main problem is that an agreement would be most useful regarding the status of space above the "territorial space" covered by the Chicago Convention As a word of caution, I would again suggest that we may not yet have the physical and scientific information needed to reach immediately the soundest decisions. The data being collected by the International Geophysical Year program will help tremendously. But it would be unfortunate if international rules of future high altitude flight control were adopted, and if it were then found that they were based on incorrect theories as to the physical characteristics and usefulness of various areas in the upper atmosphere and beyond

At this point I wish to express my appreciation to my one-time colleague at the Institute of International Air Law, Mr. R S S. Allen of London, who under my direction has done a great deal of research in certain of the problems here discussed. It was Mr. Allen who first suggested to me the advisability of three zones, although the zones which are now indicated are not exactly those he had in mind.

Certain additional questions require consideration. If a new convention is not adopted, should the International Civil Aviation Organization amend its annexes so as to expand its definition of "aircraft" to include instrumentalities which, like rockets and satellites, were not contemplated at Chicago? It must be recalled that article XII of the Chicago Convention already gives to the International Civil Aviation Organization the power to adopt flight rules as to the operation of aircraft when over the high seas. This article would have greater significance if "aircraft" included rockets and satellites when flying above the high seas.

Another problem to be dealt with is the difficult question of nationality. The whole theory of nationality, as derived from the law of the sea, is based on the concept that when a state gives to a ship the right to use its flag, such state assumes certain international responsibilities for the good conduct of that ship on the high seas and in foreign ports and at the same time acts as the protector of the ship to enforce its international rights. Under the Chicago Convention, aircraft are given the same characteristic of nationality. In addition, article VIII deals with aircraft "capable of being flown without a pilot," and it would seem that such pilotless aircraft also have nationality. While the application of the rule of nationality to rockets and satellites may be difficult, nevertheless if upper space is to be free like the high seas, then certainly a state must be prepared to be responsible for the international good conduct of its rockets and satellites; otherwise chaos might result. Nationality must be considered when these new types of flight instrumentalities are brought within the sphere of international regulation.

Assuming that decisions are made as to the legal status of the various usable zones in space and as to the legal status of flight instrumentalities not now included in the international definition of "aircraft," a further problem must be solved: Some jurists appear to doubt if the International Civil Aviation Organization, set up under the Chicago convention, should be designated as the international body to regulate and control the use of all areas of space for nonmilitary purposes, and indicate that the problems of future rocket and satellite flight in upper space are so interlinked with other international problems that some new world organization must be created to deal with the new questions involved. I am not yet convinced of the need for a new organization.

In summary, the purpose of this paper is to place before you certain basic problems. The solutions which I have tentatively suggested may not be accepted, but I do urge that as soon as the physical characteristics of the upper atmosphere and space beyond are sufficiently known to warrant the adoption of acceptable rules, then an international conference be held to amend the Chicago convention, or to adopt a new convention, so that all areas of space now usable, or which may become usable within a reasonable time, may be considered, and agreement reached as to the status of each. Agreement must also be reached as to how, and by whom, and under what circumstances, new instrumentalities of flight, such as rockets and satellites, will be regulated. It is certainly the duty of international lawyers to give these matters their earnest attention so as to be in position, when the time comes, to aid in reaching an international accord.

MISSILES AND SATELLITES: LAW AND POLICY

Address by John Cobb Cooper[1] at regional meeting of the American Bar Association, held in Atlanta, Ga., on February 22, 1958

The conquest of space is moving rapidly forward, paced by science and spurred on by national rivalries. But the law has lagged dangerously behind.

V-1 and V-2 missiles appeared toward the end of World War II, but few appreciated their significance as the beginning of a new era

The airpower of the United States was then unequalled. But it is now apparent that the Soviets had already begun careful preparation for the future. Twelve years ago in 1946 the information bulletin issued by the Soviet Embassy in Washington, on occasion of the Russian aviation day, said:

"Development of the industry is proceeding in accordance with the aim that Soviet aircraft must fly higher, faster, and further than any others, and that the Soviet plane industry must lead that of the world."

That aim still stands. Airpower is, in the last analysis, the ability of a nation to fly. Gen. William Mitchell said in 1925 that "Airpower may be defined as the ability to do something in the air." Gen. H. H. Arnold, as commanding general of the United States Army Air Forces, summed up the situation in his final report at the end of the last war as follows:

"Airpower is not composed alone of the warmaking components of aviation. It is the total aviation activity, civilian and military, commercial and private, potential as well as existing."

This I believe the Soviets have always understood.

In 1955 the United States announced its plan to launch manmade satellites in aid of the International Geophysical Year. The Soviet Government made a similar announcement, doubtless still mindful of the fundamentals of airpower and of the policy that "Soviet aircraft must fly higher, faster, and further than any others." The manmade satellite and rockets required for its launching, whether designed for scientific or military use, are products and instruments of airpower.

No concealment was made of the ultimate objective. In the issue of Pravda published June 1, 1957, the president of the Russian Academy of Sciences, writing on the subject, "The Problem of Creating an Artificial Earth Satellite," said:

"As the result of many years of work by Soviet scientists and engineers to the present time, rockets and all necessary equipment and apparatus have been created by means of which the problem of an artificial earth satellite for scientific research purposes can be solved."

During the same month the head of the U. S. S. R. International Geophysical Year committee advised the headquarters of that organization in Brussels that "in the Soviet Union during the International Geophysical Year the first launching of a manmade satellite for scientific purposes will be made." On October 4, 1957, this publicly stated program culminated in the successful launching of Sputnik I. The technical and scientific methods employed have not been disclosed, but the objective was never concealed.

A month later the second Russian satellite was launched and eventually our American Explorer. Today Sputnik II and Explorer are circling the earth at the tremendous speed of 18,000 miles per hour. These successful satellite launchings prove beyond question the development of rockets of enormous power and thrust capable also of launching missiles with nuclear warheads.

The Soviet Government claims to have developed an intercontinental missile with a range of 5,000 miles. The Soviet land mass includes about one-sixth of the land surface of the earth. From selected launching sites in that vast area missiles with a 5,000 mile range can reach almost any point on 4 continents: North America, including Alaska, Canada, the United States, and most of Mexico; all of Europe; all of continental Asia, together with Japan, Ceylon, and Indonesia; all of Africa south to Johannesburg.

The development of airpower and scientific progress have loosed forces which, uncontrolled, may well destroy the civilization which has created them. These forces are today beyond the rule of law. This should be of equal concern to the lawyers, as well as to the military experts and policymakers.

[1] Princeton, N. J.; legal adviser, International Air Transport Association; professor of international air law, McGill University, formerly, administrator, American Bar Foundation.

PRESENT STATUS OF THE LAW

Certain rules must be considered in determining the relationship of the law to the flight of guided missiles and satellites. The first of these deals with the nature of such instrumentalities of flight The regulations adopted by the International Civil Aviation Organization for the control of international flight apply to aircraft and to aircraft only. These are defined as including "all machines which can derive support in the atmosphere from reactions of the air." Satellites and rockets do not depend for their support upon the presence of gaseous air. Nor do rocket motors require the presence of gaseous air as a source of the oxygen needed for combustion; rocket fuels are self-contained. It is true that in 1926 the United States in the Air Commerce Act defined aircraft to mean "any contrivance now known or hereafter invented, used, or designed for navigation or flight in the air." In my judgment, the United States cannot insist upon this somewhat broader definition of aircraft when dealing with international flight because it has accepted without objection the definition proposed by the International Civil Aviation Organization, and now included in one of the applicable annexes to the Chicago convention of 1944, to which the United States is a party, and which is the only widely accepted convention regulating international flight

The International Civil Aviation Organization has power to submit amendments to this annex, and might broaden its definition to include rockets, missiles, and satellites But this would not cure the basic difficulty. The Soviet Union and a few other countries are not parties to the Chicago convention, and therefore not bound by the rules and regulations of the International Civil Aviation Organization. I submit to you, therefore, that there are no presently enforcible international flight regulations covering the use of rockets, guided missiles, satellites, or eventual spaceships, while in flight beyond the territory of a sovereign state.

The second rule to be considered is the extent to which a state may control flight into, through, or above its own territory.

Under presently accepted international law, so I insist, every sovereign state has complete and absolute right of control of all transport activities in its territory and has the sole right to determine what foreign instrumentalities may be permitted to enter. It should be of interest to American lawyers to recall that the United States contributed much toward the clarification and acceptance of this rule. I have in mind particularly the cogent opinion of Chief Justice Marshall in the celebrated case of the *Schooner Exchange*, in which he said in 1812 (7 Cranch 116) that all exceptions "to the full and complete power of a nation within its own territory must be traced to the consent of the nation itself." I also have in mind the vigorous rejection by Monroe as Secretary of State of the protest made by the Spanish Minister when the Spanish Government sought to challenge the right of the United States to decide what ships under which flags might be permitted to enter our ports.

The real problem therefore that arises is: What do we mean by the territory of a state? It is now accepted doctrine that such territory is in fact three dimensional, including the lands, territorial waters within its surface recognized boundaries, and also the airspace above. In the first great international aviation convention, the Paris convention of 1919, which was signed although not ratified by the United States, article I provided that "every power has complete and exclusive sovereignty over the airspace above its territory."

Kelsen, in his classic work, General Theory of Law and State, discussing this article, said:

"The territory of a state is usually considered as a definite portion of the earth's surface. This idea is incorrect. The territory of the state, as the territorial sphere of validity of the national legal order, is not a plane, but a space of three dimensions * * * The space above and below (the surface) belongs legally to the state as far as its coercive power * * * extends."

Kelsen carefully limited the geographical extent upward of the territorial area of a state in space by insisting that the "airspace * * * which is beyond the effective control of the territorial state has the character of no state's land." But he added that the territorial state below had the exclusive international right to extend its jurisdiction upward as its technical means progressed.

Under the Air Commerce Act of 1926, the subsequent Civil Aeronautics Act still in force, and through ratification of the Chicago Convention of 1944, the United States has asserted its complete and exclusive sovereignty in the airspace above it. In other words, that such airspace is part of its territory.

The U. S. S. R. is not a party to the Chicago Convention, but for years it has by statute and otherwise also asserted its sovereignty in the airspace over its

lands and waters, and has vigorously enforced its right as territorial sovereign in such area to determine what, if any, foreign instrumentalities may be permitted to enter its airspace. In fact, this is the asserted position of almost every state in the international community, and certainly of every state that is a member of the United Nations.

The present chaotic condition of the law applicable to the flight of rockets, guided missiles, and satellites stems from the fact that neither in the Paris Convention of 1919, nor in the present Chicago Convention of 1944, nor in national legislation is there any definition of what is meant by "airspace."

Some years ago I suggested the term "flight space" for future international treaties to include so much of universal space above the surface of the earth as is now used or hereafter to be used as the area in which flight takes place, defining "flight" as movement through space of man-operated and man-controlled devices or instrumentalities such as balloons, dirigibles, airplanes, rockets, guided missiles or spaceships. Satellites would, of course, be included. This term "flight space" was recently revived by Dr. Cheng of the University of London, who said that flight space should consist of two parts: namely, airspace and outer space. This emphasizes our present dilemma: Where is the boundary between airspace as part of the national territory of the state below and outer space beyond?

I am convinced, as I have said previously on several occasions, that the term "airspace" in the Paris Convention of 1919 and in the Chicago Convention of 1944 was there meant to include only those parts of the atmosphere above the surface of the earth where gaseous air is sufficiently dense to provide aerodynamic lift for balloons and airplanes, the only types of aircraft in existence when those conventions were drafted. However, I have also said and wish to repeat that nothing in the Chicago Convention precludes the possibility of state sovereignty being extended by international agreement or unfortunately by unilateral force above the area in which such airplanes and balloons can be used, but there is certainly no basis on which any customary international law can as yet be considered applicable to such higher areas.

The problem has been further complicated very recently by an official announcement of the planned construction of a new American aircraft to be known as X–15. In the statement of the Hon James H Douglas, Secretary of the Air Force, before the Preparedness Investigating Subcommittee of the Senate Armed Services Committee, he said that the Air Force had been engaged in explorations of outer space and associated technical fields since the end of World War II. Noting that with aircraft X–1 man in 1947 first exceeded the speed of sound, and with X–2 first soared to altitudes of more than 20 miles, he then said:

"The current model of these aircraft under development is the X–15, which should permit man to fly at speeds greater than 1 mile each second and at altitudes above 100 miles. I recount this continuity of development efforts to illustrate the fact that there is no easily recognized boundary between the atmosphere and space The one merges into the other and we must learn to use both. The techniques and actual developments involved in the X–15 are one path to man's flight into space. The X–15 is a step toward a manned satellite."

So it seems that we are now constructing a flight instrumentality which will move through our territorial airspace in which we have the sole right to control flight, and then into areas beyond. Sputnik I and Sputnik II in their orbits approached within approximately 125 miles of the earth's surface. X–15 will move into the same areas.

We have no rule of law, national or international, to govern such flights beyond the atmosphere. Unless this situation be rectified, chaos is before us.

POLICY: NATIONAL AND INTERNATIONAL

The United States and the other nations in the international community must, without delay, answer these questions: Where is the upper boundary of the territorial airspace? What control shall be agreed upon as to flight in areas beyond? These are policy decisions. If taken unilaterally by any powerful state, grave conflict may result. The international community must act, and act promptly.

In my judgment, international conduct during the past 3 years is leading to the acceptance of the rule that those areas of space which may be termed outer space, where there is not atmosphere of sufficient density to create drag or otherwise affect flight, is beyond the sovereignty of any state. Such course of dealing includes, among other things, the following:

(1) The announcement by the United States and the U. S. S. R. of their respective programs for satellite flight in aid of the International Geophysical Year. So far as I am advised no state above whose territory such flights would take

place made any protest, and many states participated in the scientific committees dealing with the subject.

(2) Neither the United States nor the U. S. S. R., to my knowledge, asked formal consent from all the states over which such flights would proceed—although such consent would undoubtedly have been requested and required by international law had such flights been planned to take place in the "airspace."

(3) President Eisenhower in his January 1957 state of the Union Message stated that the United States was willing to enter into any reliable agreements which would mutually control outer space missile and satellite development, followed by disarmament proposals including an inspection system to assure that outer space would be devoted exclusively for peaceful and scientific purposes.

(4) Sputnik I, Sputnik II and Explorer were launched in their several orbits. They probably passed over the surface territory of every important state in the international community. I have been able to find no record that any state has protested that such flights have violated their territorial rights.

(5) First the Political Committee and then the Assembly of the United Nations, in the latter part of 1957, adopted a resolution that the Disarmament Subcommittee should give priority to reaching a disarmament agreement to include an inspection system designed to ensure that the sending of objects through outer space would be exclusively for peaceful and scientific purposes.

(6) In President Eisenhower's historic January 12 letter to Marshal Bulganin, he stated that he was making a proposal to solve what he considered to be "the most important problem that faces the world today," and then proposed that "we agree that outer space should be used only for peaceful purposes."

It seems to me that all of these things lead to but one conclusion: Namely, that the great areas of space beyond the atmosphere are being dealt with on the basis that they are beyond the territorial sphere of any single sovereign state. This should be confirmed by a formal international agreement, vesting in some international body the power to control and regulate flight in the areas in question.

My major difficulty is that immediately above the areas of admitted national sovereignty—that is, where sufficient gaseous atmosphere exists to provide aerodynamic support for aircraft and balloons—lies an area in which there appears to be sufficient gaseous atmosphere to affect flight. For example, the data furnished me by the Mullard Radio Astronomy Observatory in Cambridge, England, indicate that the minimum height of the original orbits of both Sputnik I and Sputnik II was only about 125 miles above the earth's surface, and that the orbit time of both sputniks decreased initially each day—indicating a decrease in the maximum height of the satellite flight daily. In other words, both of these satellites came sufficiently close to the earth to be subject to drag. I do not think that we yet have sufficient scientific information from the Geophysical Year to determine whether all of this drag or a substantial part of it was caused by the presence of gaseous atmosphere. However, if, as now seems to be the case, it is found that the satellite Explorer, whose minimum orbit height above the surface of the earth is somewhat beyond 200 miles, is not materially changing its flight time daily, then it might well be argued that somewhere in the area between 125 and 225 miles above the earth's surface the atmosphere ceases to have any appreciable effect on free satellite flight.

Before Sputnik I was launched, in fact in 1956, I suggested to the American Society of International Law the basis for a policy decision to be incorporated in a new international agreement as follows:

Reaffirm article I of the Chicago Convention, giving the subjacent state full sovereignty in the areas of atmospheric space above it, up to the height where aircraft, as now defined, may be operated; such areas to be designated "territorial space";

Extend the sovereignty of the subjacent state upward to 300 miles above the earth's surface, designating this second area as "contiguous space" and provide for a right of transit through this zone for all nonmilitary flight instrumentalities, when ascending or descending;

Accept the principle that all space above "contiguous space" is free for passage of all instrumentalities.

This suggestion was made in the light of then available scientific data which appeared to indicate that future satellite flight would be practical only if conducted not less than 200 or 300 miles above the surface of the earth. At the same time I stated that the main problem was that agreement should be reached regarding the status of space above the territorial space covered by the Chicago Convention, but that we may not yet have the physical and scientific information needed to

reach immediately the soundest decisions and that it would be unfortunate if international rules of future high altitude flight control were adopted based on incorrect theories as to the physical characteristics and usefulness of various areas in the upper atmosphere and beyond.

As recently as February 8, 1958, Rt. Hon. John G. Diefenbaker, Prime Minister of Canada, in an address before the midwinter meeting of the Canadian Bar Association, when urging that an international agency to control outer space should be named by the United Nations, repeated the suggestion as to three zones which I had made in 1956—without, of course, in any way committing himself or his government as to a final decision.

As to the extent of the territorial airspace, it has been suggested recently—particularly by Mr. A G. Haley, general counsel of the American Rocket Society and president of the International Astronautical Federation—that territorial airspace should be considered as extending upward to a point where there is not sufficient gaseous atmosphere left to contribute in any way toward aerodynamic lift. This point is approximately 50 miles above the surface of the earth—about twice as far upward as any aircraft has yet penetrated. This is again a matter which might well be settled by future international agreement

Sir Leslie Munro, the Ambassador from New Zealand to the United States, and now President of the General Assembly of the United Nations, in an address before the New Jersey State Bar Association on November 22, 1957, said: "As to the actual convening of states on problems raised by recent and imminent ventures into outer space, I believe that the United Nations is the proper forum for necessary discussion " With this view I fully concur.

On January 31, 1958, Hon. Kenneth B. Keating, Member of Congress from New York, speaking before the annual meeting of the New York State Bar Association, made the following able proposal:

"I urge that the United States take the lead in formalizing international recognition of freedom of outer space. Specifically, I recommend the following three point program for international action:

"First, an immediate declaration that outer space is not subject to appropriation by any nation. This 'Freedom of Outer Space' declaration could pave the way for peaceful cooperation among all nations to best utilize the treasures of these unexplored regions.

"Second, I propose an international agreement barring the use of outer space for any military purpose.

"Third, an existing international agency should be adopted or a new one formed for the joint exploration of outer space

"Such a program is urgently needed to promote a universal dedication to the development of outer space for peaceful, scientific and humanitarian objectives."

CONCLUSION

May I therefore summarize the present situation as follows:

(1) Rockets, high altitude guided missiles, satellites and future spaceships are not aircraft and their flight is not governed by any existing agreement or regulation.

(2) States have sovereignty in the airspace above their surface territories and the right to control flight therein. This airspace includes only areas where sufficient gaseous atmosphere exists to provide aerodynamic lift for such flight instrumentalities as balloons and aircraft.

(3) Rockets, guided missiles, and satellites are actually being used today in areas of outer space beyond the territorial sphere of any state, entirely unregulated, and beyond the rule of law.

(4) No agreement exists as to where the boundary is between the territorial airspace of a state and outer space beyond—nor as to the legal status of the intermediate area lying between the territorial airspace and outer space, in which intermediate area the presence of a certain amount of gaseous atmosphere may cause the fall of flight instrumentalities, thus endangering the state below.

(5) Only the United Nations has sufficiently broad international membership to be used as the forum to determine the extent of future international agreement as to the area included in the territorial airspace of sovereign states, and how, when and where control should be vested to assure that outer space is used solely for peaceful and scientific purposes.

These are problems which the American lawyer can no longer afford to disregard.

Flight Space and the Satellites

Address by

John Cobb Cooper [1] at a meeting of British Branch of the International Law Association on November 27, 1957, at the Institute of Advanced Legal Studies, London University

On October 4, 1957, the U. S. S R launched the first manmade satellite and a second about a month later Both were equipped with wireless transmitters. Although these are no longer heard, both Sputnik I and Sputnik II are still encircling the earth several times each day. An entirely new era in transport is opening up before us.

To the international lawyer, three problems are of immediate importance:

First, what is the legal status of those areas of flight space used in the launching and eventual passage of the satellite?

Second, what is the legal status of the satellite itself?

Third, what international questions of future control of such flights and, indeed, flight space must be answered?

The launching of these Russian satellites emphasizes the fact that International Air Law, or as I would prefer to call it, international flight space law, is in one of its periods of major development The last such period was roughly between 1909 and 1919. That was the period when states in the international community were gradually accepting the basic rule that the airspace is part of the territory of the state below, and that such airspace over the high seas is free for international flight as the high seas themselves are for international shipping.

In that development London University had its part. On December 7, 1910, Prof. Harold D. Hazeltine, an American by birth though an English professor of law by training and practice, then lecturing regularly at Cambridge, delivered the first of his three lectures on "The Law of the Air" at the University of London, by request of the faculty of law (1). These were the earliest academic air law lectures ever given in the English language. The subject of his first lecture was: "The Fundamental Problem: The Rights of States in the Airspace" Professor Hazeltine brilliantly supported the position that each state is sovereign in the air space over its land and waters. The same position had been urged in Italy by Anzilotti (later to become a judge of the World Court), in Germany by Zittelmann and others, and in particular by Lycklama a Nijeholt, who had just published in English and French, and perhaps in her native Dutch, a farsighted and now classic treatise on "Air Sovereignty (2)."

The legal historian must, however, be more interested in the acts of sovereign states than in the arguments of jurists when determining the accepted rules of public international law. The period between 1909 and 1919 is replete with clear proof of such acts, demonstrating the validity of the statement that the airspace over a state is part of the territory of that state—that is to say, that national territory is three-dimensional.

A student wishing to pursue this subject will find no lack of material. It begins perhaps in 1908–09 when France protested to Germany against the flight of military balloons across the frontier, which Clemenceau, as French Minister of the Interior, sought to handle by having the balloons themselves seized for failure of the pilot to pay duty while crossing the frontier. There followed the call by France for the first International Conference on the Regulation of Air Navigation; then the holding of this Conference in Paris in 1910, at which a definite treaty was almost agreed upon, and parts of which greatly influenced the later Paris Convention of 1919 and through that convention the Chicago Convention of 1944 (3).

On the failure of international agreement, states acted quickly, by unilateral legislation or decree, to make effective their claims of the right to control flight over their territories Noteworthy was the British Act in 1911, followed by French and other decrees. In 1913 France and Germany signed the celebrated agreement severely limiting flight across their boundary Restrictive zones were named in which no flight was permitted.

In the excited days immediately preceding World War I, national air boundaries were closed. When Germany declared war on France, part of the little known actual Declaration of War recited the alleged violation of German and Belgian airspace by French military aircraft. Neutral states, by decree, denied the right

[1] Princeton, N J Member, Air Law Committee, International Law Association, legal adviser, International Air Transport Association, Fellow, American Academy of Arts and Sciences, fellow, British Interplanetary Society, member, Institute of Aeronautical Sciences, member, American Rocket Society; vice president, Pan American Airways (1934–46), member, Institute for Advanced Study, Princeton, N. J. (1946–51), Professor, International Air Law, McGill University (1951–57).

of belligerent aircraft to fly over their territories and vigorously enforced these decrees during World War I (4). The period culminated in the adoption of the great Paris Convention of 1919. Its first article recognized that "every power has complete and exclusive sovereignty over the airspace above its territory."

Since 1919 no state has questioned seriously the position that "airspace" is part of the territory of the state below. The position has been reaffirmed in the statutes and decrees of many states, including the U. S. S R and other states not parties to the Paris Convention, and has been repeated in the presently effective Chicago Convention of 1944.

The great formative 1909–19 period was thus characterized by the extension of national territory upward into the space above. The new and equally important period through which we are now passing will, in my judgment, be characterized by international acceptance of very definite upper limits on territorial sovereignty, and the determination that all areas above such limits are free for the use of all states. This is the period of limitation of sovereignty, and not of the creation of sovereignty.

The term "flight space" was suggested by me in 1951 in two definitions which I put forward in an effort to simplify legal thinking in an era when rocket flight already existed and satellite flight was already foreseen, and when the term "airspace" was rapidly becoming a vehicle for confused rather than accurate international thinking. These definitions were as follows:

"Flight" includes any movement through space of man-operated or man-controlled devices or instrumentalities (to be known as flight instrumentalities), such as balloons, dirigibles, airplanes, rockets, guided missiles, or spaceships

"Flightspace" means so much of universal space above and beyond the surface of the earth as is now used or may hereafter be used as the area in which flight takes place (5).

In his recent excellent article on "International Law and High Altitude Flights," (6) Dr. Bin Cheng of University College, London, has revived the suggested term "flight space" and deals with it as consisting of two parts, namely "airspace" and "outer space." The result may be the same as my earlier definition. His definition has the advantage that it emphasizes the dilemma before us: Where is the boundary between the "airspace" which is part of the national territory of the state below, and "outer space?"

Much has been written, but little has been decided, as to what is meant by the term "airspace" It was certainly not discussed at the Chicago Conference in 1944. The drafting committee of which I then had the honor to be chairman presented the present article I of the Chicago convention in almost the exact language of the Paris convention of 1919—namely, every state has complete and exclusive sovereignty over the airspace above its territory. After many years of careful research, I am convinced that the term "airspace," as used in the Paris convention of 1919, was there meant to include only those parts of the atmosphere above the surface of the earth where gaseous air is sufficiently dense to support balloons and airplanes, the only types of aircraft then in existence. The annexes to the Paris convention describe an aircraft as "any machine that can derive support in the atmosphere from the reactions of the air." These annexes were part of the Paris convention.

The annexes to the Chicago convention of 1944 now in force, although legally not part of the convention, have been accepted by member states, which include practically all of the great flying nations with the exception of the U. S. S R. The definition of "aircraft" in the annexes to the Chicago convention is the same as that in the annexes to the Paris convention.

My views today are just as they were in 1956 when these matters were discussed at some length at the annual meeting of the American Society of International Law (7). I then said what I now wish to repeat, namely

"The Chicago convention contains no definition of 'airspace,' but it may well be argued that, as it was adapted from the Paris convention, it deals with no areas of space other than those parts of the atmosphere where the gaseous air is sufficiently dense to support balloons and airplanes * * *.

"Nothing in the Chicago convention precludes the possibility of state sovereignty being extended by international agreement, or by unilateral force, above the areas in which the airplane and balloon can be used, but there is certainly no basis on which any customary international law can as yet be considered applicable to such higher areas"

Any careful reading of what I said then and have since said as to possible further upward extension of air sovereignty (8) will disclose that I have always insisted that an agreement would be needed before national soveriegnty of any

state could be recognized in areas above those where sufficiently dense gaseous atmosphere will exist to provide aeronautical lift for airplanes and balloons.

It may be useful to examine the present status of the practical use now being made of this atmospheric space.

During the past year, on August 19, 1957, Major Simons in the United States ascended in a specially constructed balloon to a distance of approximately 100,000 feet, or somewhat over 19 miles (9). On August 28, 1957, a Canberra B–2 aircraft in the United Kingdom was credited with an official altitude height of approximately 70,100 feet, or about 13 miles, which I believe is the highest official record to date. In September 1956, the experimental craft known as X–2, driven by rocket motors, was destroyed with all its instruments on a flight in which its pilot was killed. Unofficially, this rocket-powered aircraft was understood to have reached speeds of at least 1,900 miles per hour, and to have attained a height of approximately 24 miles (10).

Without becoming too technical, I must remind you that there are two factors which limit the height to which an aircraft may proceed. One is the aeronautical lift provided by its design, the other is a question of motive power. Normal types of aircraft engines, both piston driven, turboprop, or jet, are to some extent "air breathing," that is to say, their effectiveness depends on taking gaseous oxygen out of surrounding air and using it in combination with petrol or other fuel to drive the motor. On the other hand, the rocket engine carries its own oxygen supply in its self-contained fuel. A rocket engine, therefore, operates equally well through the atmosphere and through space beyond. The X–2 is understood to have had such rocket power. In the flight of the Canberra B–2 referred to above, I am advised that jet power was used up to about 40,000 feet, and at that point rocket power was turned on, and not turned off until the aircraft had reached its recorded maximum height of 70,000 feet.

Although rocket power has thus made it possible for aircraft requiring atmospheric support to ascend far above the areas where they might be driven by older powerplants, nevertheless I do not feel that the legal position has been altered. They are still operating within the "airspace" which is part of the territory of the state below. However, a new and completely different problem will arise if future types of aircraft, driven by rocket power, ascend through the atmosphere in normal flight, and then continue beyond as a rocket-powered space craft. Reference has recently been made to an aircraft, described as X–15, which it is said "should go up 100 miles at 3,500 miles per hour" (11). About this aircraft I know nothing further. But if it is put successfully into flight, I am quite certain as a lawyer that it will ascend far beyond the areas of atmospheric space which are admittedly part of the territory of the state below.

Returning then to the major problem as to where territorial "airspace" ends and where "outer space" begins, I must direct your attention to a series of international events which appear to indicate the beginning of a new rule of customary international law holding that "outer space" is not part of the territory of the state below.

In 1956 the United States announced a program of planned satellite flights in aid of the International Geophysical Year. The proposed satellites were to contain instruments to study various physical phenomena, the details of which are not important here. Shortly afterward the U. S. S. R. indicated a similar plan. So far as I can ascertain neither the United States nor the U. S. S. R. asked any formal permission of other states to place the proposed satellites in space several hundred miles above those parts of the earth which would be covered by the flight orbits. On the other hand, as is well known, no international flight by aircraft of any state through the atmospheric territorial space of another state is permissible without the general or specific authority of the state affected.

Also no record exists that any state protested against the proposed international satellite flights. While it has been suggested that the various agreements between the scientific committees promoting the Geophysical Year may have been supported sufficiently by the several governments concerned as to be considered legally equivalent to international agreements permitting such satellite flights, this argument would fail insofar as those states are concerned which are not part of the Geophysical Year program and over whose territories the satellites would proceed.

Next, in order of time, was the statement in President Eisenhower's January 1957 state of the Union message to the effect that the United States was willing to enter into any reliable agreements which would mutually control the outer space missile and satellite development (12). A few days later, the United States representative to the United Nations, addressing a committee of the General Assembly, is reported in the press to have said that "the first step toward the

objective of assuring that developments in outer space would be devoted exclusively to peaceful and scientific purposes would be to bring the testing of such objects under international inspection and participation" (13).

Later, in July, a proposal was put before the Subcommittee of the Disarmament Commission meeting in London, which suggested the inclusion in a possible disarmament convention of the following

"THE CONTROL OF OBJECTS ENTERING OUTER SPACE

"All parties to the convention agree that within 3 months after the entry into effect of the convention they will cooperate in the establishment of a technical committee to study the design of an inspection system which would make it possible to assure that the sending of objects through outer space will be exclusively for peaceful and scientific purposes" (14).

This was supported by Canada, France, the United Kingdom, and the United States.

Sputnik I was launched on October 4, 1957. The satellite itself, as well as the last stage of the rocket which launched it, are still circling the earth several times daily. The course of the orbit is such that they have probably passed over the surface territory of every member of the United Nations, and many other states as well. I have not been able to find any record that states have protested against such flights as violating their territorial rights

While these flights were continuing, disarmament proposals were adopted by the Political Committee of the United Nations on November 6 (15). A resolution sponsored by Canada, France, the United Kingdom, the United States, and a number of other nations stated that the Disarmament Subcommittee should give priority to reaching a disarmament agreement which, on entering into force, would provide for various things, including the "joint study of an inspection system designed to insure that the sending of objects through outer space will be exclusively for peaceful and scientific purposes." This is practically the same proposal earlier suggested in the Disarmament Subcommittee.

According to very recent press reports, the Political Committee proposal has been approved by the Assembly of the United Nations

Taking all of these official and semiofficial acts together, I feel as a lawyer that the course of international conduct since the satellite flights were first announced is consistent with no theory other than the acceptance of the principle that "outer space" is not part of the territory of any state and may be used by all states as freely as the high seas are now used for surface shipping.

This emphasizes, however, the present major difficulty—what is meant by "outer space"? I submit for your consideration that immediately above the area of admitted national sovereignty, namely where sufficient gaseous atmosphere exists to support aircraft or balloon flight, is an area in which there appears to be sufficient gaseous atmosphere to affect flight. The Mullard Radio Astronomy Observatory at Cambridge, whose brilliant work in the technical observations of the sputnik flights I cannot praise too highly, advises me as follows: Minimum height of the orbit of Sputnik I is about 200 kilometers (about 125 miles) above the earth's surface, and its maximum is about 930 kilometers (about 590 miles). The minimum height of the orbit of Sputnik II is again about 200 kilometers (125 miles) above us and at the maximum about 1,600 kilometers (about 1,000 miles). The orbit time of Sputnik I decreased initially by 2 seconds a day, indicating a decrease in the maximum height of the satellite of about 3.5 kilometers (2$\frac{2}{10}$ miles) a day, and the orbit time of Sputnik II decreased at about the same rate, corresponding to a similar decrease in the maximum height of the orbit as in the case of Sputnik I. I have roughly transposed the figures in kilometers furnished me by the Mullard Laboratory into miles for the purpose of the present discussion.

The importance of these figures is that they seem to constitute definite proof that the lower portion of the orbits of both Sputnik I and Sputnik II are closer to the earth than some earlier scientific analyses had deemed practical for effective satellite flight. At the same time, the figures show that these lower parts of the orbit must be within an area in which there is sufficient gaseous atmosphere to create some "drag" so as to affect the period of time during which the statellites smay continue on their courses. The same lower parts of the orbits are, however, above these atmospheric areas which would cause heating so as to destroy the satellites. They will doubtless continue on their orbits until they reach those dense lower strata where destruction may well result from the enormous heat created by an object proceeding at 18,000 miles an hour.

To sum up my views: I believe we are entering a period where international conduct as well as legal doctrine will demonstrate:

(a) that the present territory of every state extends upward only to a point where gaseous air becomes so thin as to provide no aeronautical lift supporting flights of aircraft or balloons;

(b) that "outer space," where there is no atmosphere of sufficient density to create "drag" or otherwise affect flight, is now beyond the sovereignty of any state;

(c) that an international decision must be made by treaty, or otherwise, to determine the exact future status of those areas of atmospheric space which lie between the areas of practical aeronautical lift and the areas referred to in (b) above as "outer space"

The remaining two problems may be dealt with briefly. It is obvious from what has been said earlier that a satellite is not an aircraft subject to the present existing international regulations However, I submit, it is quite necessary that this future formal international agreement should provide means for such regulation. Such an agreement will certainly require that the state responsible for the launching of the satellite will also be subsequently responsible for its international good conduct.

So far as future regulations of areas of "outer space" which are not part of the sovereignty of any state are concerned, you may be interested in the recommendations very recently made by a distinguished group in the United States (of which I am not a member) known as the Commission to Study the Organization of Peace. It is the research affiliate of the American Association for the United Nations. In this report (16) the Commission has recommended that the United Nations undertake the responsibility of administering certain areas "which are outside the jurisdiction of any state" including "outer space," and that the General Assembly declare the title of the international community and establish the appropriate administrative arrangements. In the detailed statement by a study group of the Commission on which these recommendations are based, it was urged that the principle should be accepted that outer space is not subject to ownership or control by individual states, but only by the international community, represented by the United Nations. In the alternative, it was suggested that international ownership and operation of all or certain types of space craft and verification of flights be adopted as a short-term policy regarding earth satellites, but only after more than one nation had launched such a satellite. These recommendations were drafted before Sputnik I was launched.

Such proposals pose questions of future international policy. It is the primary province of the international lawyer to determine the present status of the law. At the Washington meeting of the Society of International Law, I went further and suggested for future consideration possible extension of sovereignty by agreement up to 300 miles above the surface of the earth, so as to include areas of "drag." Such a suggestion was entirely tentative, as I said, depending upon what was found in the research of the Geophysical Year as to actual conditions in upper atmospheric space (17). Very recently, in a letter to the London Times (18), I suggested that it might be advisable to extend such sovereignty by agreement up to 600 miles as part of any disarmament agreement, so as to protect neutral states from the uncontrollable flight of guided missiles on high trajectories. These are nothing more than statements of my personal views as to possible international policy. They do not in any way change the carefully considered views which I have expressed earlier with reference to the present status of the law.

In conclusion, may I ask that you understand that nothing here put forward is stated as the views of any organization with which I am associated or any committees of which I am a member Recently the International Astronautical Federation set up a committee which is charged with preparing a statement for possible submission to the United Nations and the International Civil Aviation Organization regarding the extent of the airspace and the resulting jurisdictional problems. With reluctance I accepted the chairmanship of this committee. I do not want either those of you who are here today or my colleagues on that committee to think that I have sought to prejudge any decision which the committee may hereafter make

(Executive O is in the committee files. The text of the Chicago convention follows:)

CONVENTION ON INTERNATIONAL CIVIL AVIATION

PREAMBLE

WHEREAS the future development of international civil aviation can greatly help to create and preserve friendship and understanding among the nations and peoples of the world, yet its abuse can become a threat to the general security; and

WHEREAS it is desirable to avoid friction and to promote that cooperation between nations and peoples upon which the peace of the world depends;

THEREFORE, the undersigned governments having agreed on certain principles and arrangements in order that international civil aviation may be developed in a safe and orderly manner and that international air transport services may be established on the basis of equality of opportunity and operated soundly and economically;

Have accordingly concluded this Convention to that end.

PART I. AIR NAVIGATION

CHAPTER I

GENERAL PRINCIPLES AND APPLICATION OF THE CONVENTION

Article 1

The contracting States recognize that every State has complete and exclusive sovereignty over the airspace above its territory. Sovereignty

Article 2

For the purposes of this Convention the territory of a State shall be deemed to be the land areas and territorial waters adjacent thereto under the sovereignty, suzerainty, protection or mandate of such State. Territory

Article 3

(a) This Convention shall be applicable only to civil aircraft, and shall not be applicable to state aircraft. Civil and state aircraft

(b) Aircraft used in military, customs and police services shall be deemed to be state aircraft.

(c) No state aircraft of a contracting State shall fly over the territory of another State or land thereon without authorization by special agreement or otherwise, and in accordance with the terms thereof.

(d) The contracting States undertake, when issuing regulations for their state aircraft, that they will have due regard for the safety of navigation of civil aircraft.

Article 4

Misuse of civil aviation

Each contracting State agrees not to use civil aviation for any purpose inconsistent with the aims of this Convention.

CHAPTER II

FLIGHT OVER TERRITORY OF CONTRACTING STATES

Article 5

Right of non-scheduled flight

Each contracting State agrees that all aircraft of the other contracting States, being aircraft not engaged in scheduled international air services shall have the right, subject to the observance of the terms of this Convention, to make flights into or in transit non-stop across its territory and to make stops for non-traffic purposes without the necessity of obtaining prior permission, and subject to the right of the State flown over to require landing. Each contracting State nevertheless reserves the right, for reasons of safety of flight, to require aircraft desiring to proceed over regions which are inaccessible or without adequate air navigation facilities to follow prescribed routes, or to obtain special permission for such flights.

Such aircraft, if engaged in the carriage of passengers, cargo, or mail for remuneration or hire on other than scheduled international air services, shall also, subject to the provisions of Article 7, have the privilege of taking on or discharging passengers, cargo, or mail, subject to the right of any State where such embarkation or discharge takes place to impose such regulations, conditions or limitations as it may consider desirable.

Article 6

Scheduled air services

No scheduled international air service may be operated over or into the territory of a contracting State, except with the special permission or other authorization of that

State, and in accordance with the terms of such permission or authorization.

Article 7

Each contracting State shall have the right to refuse permission to the aircraft of other contracting States to take on in its territory passengers, mail and cargo carried for remuneration or hire and destined for another point within its territory. Each contracting State undertakes not to enter into any arrangements which specifically grant any such privilege on an exclusive basis to any other State or an airline of any other State, and not to obtain any such exclusive privilege from any other State. Cabotage

Article 8

No aircraft capable of being flown without a pilot shall be flown without a pilot over the territory of a contracting State without special authorization by that State and in accordance with the terms of such authorization. Each contracting State undertakes to insure that the flight of such aircraft without a pilot in regions open to civil aircraft shall be so controlled as to obviate danger to civil aircraft. Pilotless aircraft

Article 9

(a) Each contracting State may, for reasons of military necessity or public safety, restrict or prohibit uniformly the aircraft of other States from flying over certain areas of its territory, provided that no distinction in this respect is made between the aircraft of the State whose territory is involved, engaged in international scheduled airline services, and the aircraft of the other contracting States likewise engaged. Such prohibited areas shall be of reasonable extent and location so as not to interfere unnecessarily with air navigation. Descriptions of such prohibited areas in the territory of a contracting State, as well as any subsequent alterations therein, shall be communicated as soon as possible to the other contracting States and to the International Civil Aviation Organization. Prohibited areas

(b) Each contracting State reserves also the right, in exceptional circumstances or during a period of emergency, or in the interest of public safety, and with immediate effect, temporarily to restrict or prohibit flying over the whole or any part of its territory, on condition that

such restriction or prohibition shall be applicable without distinction of nationality to aircraft of all other States.

(c) Each contracting State, under such regulations as it may prescribe, may require any aircraft entering the areas contemplated in subparagraphs (a) or (b) above to effect a landing as soon as practicable thereafter at some designated airport within its territory.

Article 10

Landing at customs airport

Except in a case where, under the terms of this Convention or a special authorization, aircraft are permitted to cross the territory of a contracting State without landing, every aircraft which enters the territory of a contracting State shall, if the regulations of that State so require, land at an airport designated by that State for the purpose of customs and other examination. On departure from the territory of a contracting State, such aircraft shall depart from a similarly designated customs airport. Particulars of all designated customs airports shall be published by the State and transmitted to the International Civil Aviation Organization established under Part II of this Convention for communication to all other contracting States.

Article 11

Applicability of air regulations

Subject to the provisions of this Convention, the laws and regulations of a contracting State relating to the admission to or departure from its territory of aircraft engaged in international air navigation, or to the operation and navigation of such aircraft while within its territory, shall be applied to the aircraft of all contracting States without distinction as to nationality, and shall be complied with by such aircraft upon entering or departing from or while within the territory of that State.

Article 12

Rules of the air

Each contracting State undertakes to adopt measures to insure that every aircraft flying over or maneuvering within its territory and that every aircraft carrying its nationality mark, wherever such aircraft may be, shall comply with the rules and regulations relating to the flight and maneuver of aircraft there in force. Each contracting State undertakes to keep its own regulations in these respects uniform, to the greatest possible extent,

with those established from time to time under this Convention. Over the high seas, the rules in force shall be those established under this Convention. Each contracting State undertakes to insure the prosecution of all persons violating the regulations applicable.

Article 13

Entry and clearance regulations

The laws and regulations of a contracting State as to the admission to or departure from its territory of passengers, crew or cargo of aircraft, such as regulations relating to entry, clearance, immigration, passports, customs, and quarantine shall be complied with by or on behalf of such passengers, crew or cargo upon entrance into or departure from, or while within the territory of that State.

Article 14

Prevention of spread of disease

Each contracting State agrees to take effective measures to prevent the spread by means of air navigation of cholera, typhus (epidemic), smallpox, yellow fever, plague, and such other communicable diseases as the contracting States shall from time to time decide to designate, and to that end contracting States will keep in close consultation with the agencies concerned with international regulations relating to sanitary measures applicable to aircraft. Such consultation shall be without prejudice to the application of any existing international convention on this subject to which the contracting States may be parties.

Article 15

Airport and similar charges

Every airport in a contracting State which is open to public use by its national aircraft shall likewise, subject to the provisions of Article 68, be open under uniform conditions to the aircraft of all the other contracting States. The like uniform conditions shall apply to the use, by aircraft of every contracting State, of all air navigation facilities, including radio and meteorological services, which may be provided for public use for the safety and expedition of air navigation.

Any charges that may be imposed or permitted to be imposed by a contracting State for the use of such airports and air navigation facilities by the aircraft of any other contracting State shall not be higher,

25973 O—58——86

(a) As to aircraft not engaged in scheduled international air services, than those that would be paid by its national aircraft of the same class engaged in similar operations, and

(b) As to aircraft engaged in scheduled international air services, than those that would be paid by its national aircraft engaged in similar international air services.

All such charges shall be published and communicated to the International Civil Aviation Organization: provided that, upon representation by an interested contracting State, the charges imposed for the use of airports and other facilities shall be subject to review by the Council, which shall report and make recommendations thereon for the consideration of the State or States concerned. No fees, dues or other charges shall be imposed by any contracting State in respect solely of the right of transit over or entry into or exit from its territory of any aircraft of a contracting State or persons or property thereon.

Article 16

Search of aircraft

The appropriate authorities of each of the contracting States shall have the right, without unreasonable delay, to search aircraft of the other contracting States on landing or departure, and to inspect the certificates and other documents prescribed by this Convention.

CHAPTER III

NATIONALITY OF AIRCRAFT

Article 17

Nationality of aircraft

Aircraft have the nationality of the State in which they are registered.

Article 18

Dual registration

An aircraft cannot be validly registered in more than one State, but its registration may be changed from one State to another.

Article 19

National laws governing registration

The registration or transfer of registration of aircraft in any contracting State shall be made in accordance with its laws and regulations.

Article 20

Every aircraft engaged in international air navigation shall bear its appropriate nationality and registration marks. Display of marks

Article 21

Each contracting State undertakes to supply to any other contracting State or to the International Civil Aviation Organization, on demand, information concerning the registration and ownership of any particular aircraft registered in that State. In addition, each contracting State shall furnish reports to the International Civil Aviation Organization, under such regulations as the latter may prescribe, giving such pertinent data as can be made available concerning the ownership and control of aircraft registered in that State and habitually engaged in international air navigation. The data thus obtained by the International Civil Aviation Organization shall be made available by it on request to the other contracting States. Report of registrations

Chapter IV

MEASURES TO FACILITATE AIR NAVIGATION

Article 22

Each contracting State agrees to adopt all practicable measures, through the issuance of special regulations or otherwise, to facilitate and expedite navigation by aircraft between the territories of contracting States, and to prevent unnecessary delays to aircraft, crews, passengers and cargo, especially in the administration of the laws relating to immigration, quarantine, customs and clearance. Facilitation of formalities

Article 23

Each contracting State undertakes, so far as it may find practicable, to establish customs and immigration procedures affecting international air navigation in accordance with the practices which may be established or recommended from time to time, pursuant to this Convention. Nothing in this Convention shall be construed as preventing the establishment of customs-free airports. Customs and immigration procedures

Article 24

(a) Aircraft on a flight to, from, or across the territory of another contracting State shall be admitted tem- Customs duty

porarily free of duty, subject to the customs regulations of the State. Fuel, lubricating oils, spare parts, regular equipment and aircraft stores on board an aircraft of a contracting State, on arrival in the territory of another contracting State and retained on board on leaving the territory of that State shall be exempt from customs duty, inspection fees or similar national or local duties and charges. This exemption shall not apply to any quantities or articles unloaded, except in accordance with the customs regulations of the State, which may require that they shall be kept under customs supervision.

(b) Spare parts and equipment imported into the territory of a contracting State for incorporation in or use on an aircraft of another contracting State engaged in international air navigation shall be admitted free of customs duty, subject to compliance with the regulations of the State concerned, which may provide that the articles shall be kept under customs supervision and control.

Article 25

Aircraft in distress

Each contracting State undertakes to provide such measures of assistance to aircraft in distress in its territory as it may find practicable, and to permit, subject to control by its own authorities, the owners of the aircraft or authorities of the State in which the aircraft is registered to provide such measures of assistance as may be necessitated by the circumstances. Each contracting State, when undertaking search for missing aircraft, will collaborate in coordinated measures which may be recommended from time to time pursuant to this Convention.

Article 26

Investigation of accidents

In the event of an accident to an aircraft of a contracting State occurring in the territory of another contracting State, and involving death or serious injury, or indicating serious technical defect in the aircraft or air navigation facilities, the State in which the accident occurs will institute an inquiry into the circumstances of the accident, in accordance, so far as its laws permit, with the procedure which may be recommended by the International Civil Aviation Organization. The State in which the aircraft is registered shall be given the opportunity to appoint observers to be present at the inquiry and the State holding the inquiry shall commu-

nicate the report and findings in the matter to that State.

Article 27

(a) While engaged in international air navigation, any authorized entry of aircraft of a contracting State into the territory of another contracting State or authorized transit across the territory of such State with or without landings shall not entail any seizure or detention of the aircraft or any claim against the owner or operator thereof or any other interference therewith by or on behalf of such State or any person therein, on the ground that the construction, mechanism, parts, accessories or operation of the aircraft is an infringement of any patent, design, or model duly granted or registered in the State whose territory is entered by the aircraft, it being agreed that no deposit of security in connection with the foregoing exemption from seizure or detention of the aircraft shall in any case be required in the State entered by such aircraft. Exemption from seizure on patent claims

(b) The provisions of paragraph (a) of this Article shall also be applicable to the storage of spare parts and spare equipment for the aircraft and the right to use and install the same in the repair of an aircraft of a contracting State in the territory of any other contracting State, provided that any patented part or equipment so stored shall not be sold or distributed internally in or exported commercially from the contracting State entered by the aircraft.

(c) The benefits of this Article shall apply only to such States, parties to this Convention, as either (1) are parties to the International Convention for the Protection of Industrial Property and to any amendments thereof; or (2) have enacted patent laws which recognize and give adequate protection to inventions made by the nationals of the other States parties to this Convention.

Article 28

Each contracting State undertakes, so far as it may find practicable, to: Air navigation facilities and standard systems

(a) Provide, in its territory, airports, radio services, meteorological services and other air navigation facilities to facilitate international air navigation, in accordance with the standards and practices recom-

mended or established from time to time, pursuant to this Convention;

(b) Adopt and put into operation the appropriate standard systems of communications procedure, codes, markings, signals, lighting and other operational practices and rules which may be recommended or established from time to time, pursuant to this Convention;

(c) Collaborate in international measures to secure the publication of aeronautical maps and charts in accordance with standards which may be recommended or established from time to time, pursuant to this Convention.

CHAPTER V

CONDITIONS TO BE FULFILLED WITH RESPECT TO AIRCRAFT

Article 29

Documents carried in aircraft

Every aircraft of a contracting State, engaged in international navigation, shall carry the following documents in conformity with the conditions prescribed in this Convention:

(a) Its certificate of registration;

(b) Its certificate of airworthiness;

(c) The appropriate licenses for each member of the crew;

(d) Its journey log book;

(e) If it is equipped with radio apparatus, the aircraft radio station license;

(f) If it carries passengers, a list of their names and places of embarkation and destination;

(g) If it carries cargo, a manifest and detailed declarations of the cargo.

Article 30

Aircraft radio equipment

(a) Aircraft of each contracting State may, in or over the territory of other contracting States, carry radio transmitting apparatus only if a license to install and operate such apparatus has been issued by the appropriate authorities of the State in which the aircraft is registered. The use of radio transmitting apparatus in the territory of the contracting State whose territory is flown over shall be in accordance with the regulations prescribed by that State.

(b) Radio transmitting apparatus may be used only by members of the flight crew who are provided with a special license for the purpose, issued by the appropriate authorities of the State in which the aircraft is registered.

Article 31

Certificates of airworthiness

Every aircraft engaged in international navigation shall be provided with a certificate of airworthiness issued or rendered valid by the State in which it is registered.

Article 32

Licenses of personnel

(a) The pilot of every aircraft and the other members of the operating crew of every aircraft engaged in international navigation shall be provided with certificates of competency and licenses issued or rendered valid by the State in which the aircraft is registered.

(b) Each contracting State reserves the right to refuse to recognize, for the purpose of flight above its own territory, certificates of competency and licenses granted to any of its nationals by another contracting State.

Article 33

Recognition of certificates and licenses

Certificates of airworthiness and certificates of competency and licenses issued or rendered valid by the contracting State in which the aircraft is registered, shall be recognized as valid by the other contracting States, provided that the requirements under which such certificates or licenses were issued or rendered valid are equal to or above the minimum standards which may be established from time to time pursuant to this Convention.

Article 34

Journey log books

There shall be maintained in respect of every aircraft engaged in international navigation a journey log book in which shall be entered particulars of the aircraft, its crew and of each journey, in such form as may be prescribed from time to time pursuant to this Convention.

Article 35

Cargo restrictions

(a) No munitions of war or implements of war may be carried in or above the territory of a State in aircraft engaged in international navigation, except by permission of such State. Each State shall determine by regulations what constitutes munitions of war or implements

of war for the purposes of this Article, giving due consideration, for the purposes of uniformity, to such recommendations as the International Civil Aviation Organization may from time to time make.

(b) Each contracting State reserves the right, for reasons of public order and safety, to regulate or prohibit the carriage in or above its territory of articles other than those enumerated in paragraph (a): provided that no distinction is made in this respect between its national aircraft engaged in international navigation and the aircraft of the other States so engaged; and provided further that no restriction shall be imposed which may interfere with the carriage and use on aircraft of apparatus necessary for the operation or navigation of the aircraft or the safety of the personnel or passengers.

Article 36

Photographic apparatus

Each contracting State may prohibit or regulate the use of photographic apparatus in aircraft over its territory.

Chapter VI

INTERNATIONAL STANDARDS AND RECOMMENDED PRACTICES

Article 37

Adoption of international standards and procedures

Each contracting State undertakes to collaborate in securing the highest practicable degree of uniformity in regulations, standards, procedures, and organization in relation to aircraft, personnel, airways and auxiliary services in all matters in which such uniformity will facilitate and improve air navigation.

To this end the International Civil Aviation Organization shall adopt and amend from time to time, as may be necessary, international standards and recommended practices and procedures dealing with:

(a) Communications systems and air navigation aids, including ground marking;

(b) Characteristics of airports and landing areas;

(c) Rules of the air and air traffic control practices;

(d) Licensing of operating and mechanical personnel;

(e) Airworthiness of aircraft;

(f) Registration and identification of aircraft;

(g) Collection and exchange of meteorological information;

(h) Log books;

(i) Aeronautical maps and charts;

(j) Customs and immigration procedures;

(k) Aircraft in distress and investigation of accidents;

and such other matters concerned with the safety, regularity, and efficiency of air navigation as may from time to time appear appropriate.

Article 38

Departures from international standards and procedures

Any State which finds it impracticable to comply in all respects with any such international standard or procedure, or to bring its own regulations or practices into full accord with any international standard or procedure after amendment of the latter, or which deems it necessary to adopt regulations or practices differing in any particular respect from those established by an international standard, shall give immediate notification to the International Civil Aviation Organization of the differences between its own practice and that established by the international standard. In the case of amendments to international standards, any State which does not make the appropriate amendments to its own regulations or practices shall give notice to the Council within sixty days of the adoption of the amendment to the international standard, or indicate the action which it proposes to take. In any such case, the Council shall make immediate notification to all other states of the difference which exists between one or more features of an international standard and the corresponding national practice of that State.

Article 39

Endorsement of certificates and licenses

(a) Any aircraft or part thereof with respect to which there exists an international standard of airworthiness or performance, and which failed in any respect to satisfy that standard at the time of its certification, shall have endorsed on or attached to its airworthiness certificate a complete enumeration of the details in respect of which it so failed.

(b) Any person holding a license who does not satisfy in full the conditions laid down in the international standard relating to the class of license or certificate which he holds shall have endorsed on or attached to his license a complete enumeration of the particulars in which he does not satisfy such conditions.

Article 40

Validity of endorsed certificates and licenses

No aircraft or personnel having certificates or licenses so endorsed shall participate in international navigation, except with the permission of the State or States whose territory is entered. The registration or use of any such aircraft, or of any certificated aircraft part, in any State other than that in which it was originally certificated shall be at the discretion of the State into which the aircraft or part is imported.

Article 41

Recognition of existing standards of airworthiness

The provisions of this Chapter shall not apply to aircraft and aircraft equipment of types of which the prototype is submitted to the appropriate national authorities for certification prior to a date three years after the date of adoption of an international standard of airworthiness for such equipment.

Article 42

Recognition of existing standards of competency of personnel

The provisions of this Chapter shall not apply to personnel whose licenses are originally issued prior to a date one year after initial adoption of an international standard of qualification for such personnel; but they shall in any case apply to all personnel whose licenses remain valid five years after the date of adoption of such standard.

PART II. THE INTERNATIONAL CIVIL AVIATION ORGANIZATION

CHAPTER VII

THE ORGANIZATION

Article 43

Name and composition

An organization to be named the International Civil Aviation Organization is formed by the Convention. It

is made up of an Assembly, a Council, and such other bodies as may be necessary.

Article 44

Objectives

The aims and objectives of the Organization are to develop the principles and techniques of international air navigation and to foster the planning and development of international air transport so as to:

(a) Insure the safe and orderly growth of international civil aviation throughout the world;

(b) Encourage the arts of aircraft design and operation for peaceful purposes;

(c) Encourage the development of airways, airports, and air navigation facilities for international civil aviation;

(d) Meet the needs of the peoples of the world for safe, regular, efficient and economical air transport;

(e) Prevent economic waste caused by unreasonable competition;

(f) Insure that the rights of contracting States are fully respected and that every contracting State has a fair opportunity to operate international airlines;

(g) Avoid discrimination between contracting States;

(h) Promote safety of flight in international air navigation;

(i) Promote generally the development of all aspects of international civil aeronautics.

Article 45

Permanent seat

The permanent seat of the Organization shall be at such place as shall be determined at the final meeting of the Interim Assembly of the Provisional International Civil Aviation Organization set up by the Interim Agreement on International Civil Aviation signed at Chicago on December 7, 1944. The seat may be temporarily transferred elsewhere by decision of the Council.

Article 46

First meeting of Assembly

The first meeting of the Assembly shall be summoned by the Interim Council of the above-mentioned Provisional Organization as soon as the Convention has come into force, to meet at a time and place to be decided by the Interim Council.

Article 47

Legal capacity

The Organization shall enjoy in the territory of each contracting State such legal capacity as may be necessary for the performance of its functions. Full juridical personality shall be granted wherever compatible with the constitution and laws of the State concerned.

CHAPTER VIII

THE ASSEMBLY

Article 48

Meetings of Assembly and voting

(a) The Assembly shall meet annually and shall be convened by the Council at a suitable time and place. Extraordinary meetings of the Assembly may be held at any time upon the call of the Council or at the request of any ten contracting States addressed to the Secretary General.

(b) All contracting States shall have an equal right to be represented at the meetings of the Assembly and each contracting State shall be entitled to one vote. Delegates representing contracting States may be assisted by technical advisers who may participate in the meetings but shall have no vote.

(c) A majority of the contracting States is required to constitute a quorum for the meetings of the Assembly. Unless otherwise provided in this Convention, decisions of the Assembly shall be taken by a majority of the votes cast.

Article 49

Powers and duties of Assembly

The powers and duties of the Assembly shall be to:

(a) Elect at each meeting its President and other officers;

(b) Elect the contracting States to be represented on the Council, in accordance with the provisions of Chapter IX;

(c) Examine and take appropriate action on the reports of the Council and decide on any matter referred to it by the Council;

(d) Determine its own rules of procedure and establish such subsidiary commissions as it may consider to be necessary or desirable;

(e) Vote an annual budget and determine the financial arrangements of the Organization, in accordance with the provisions of Chapter XII;

(f) Review expenditures and approve the accounts of the Organization;

(g) Refer, at its discretion, to the Council, to subsidiary commissions, or to any other body any matter within its sphere of action;

(h) Delegate to the Council the powers and authority necessary or desirable for the discharge of the duties of the Organization and revoke or modify the delegations of authority at any time;

(i) Carry out the appropriate provisions of Chapter XIII;

(j) Consider proposals for the modification or amendment of the provisions of this Convention and, if it approves of the proposals, recommend them to the contracting States in accordance with the provisions of Chapter XXI;

(k) Deal with any matter within the sphere of action of the Organization not specifically assigned to the Council.

Chapter IX

THE COUNCIL

Article 50

Composition and election of Council

(a) The Council shall be a permanent body responsible to the Assembly. It shall be composed of twenty-one contracting States elected by the Assembly. An election shall be held at the first meeting of the Assembly and thereafter every three years, and the members of the Council so elected shall hold office until the next following election.

(b) In electing the members of the Council, the Assembly shall give adequate representation to (1) the States of chief importance in air transport; (2) the States not otherwise included which make the largest contribution to the provision of facilities for international civil air navigation; and (3) the States not otherwise included whose designation will insure that all the major geographic areas of the world are represented on the Council. Any vacancy on the Council shall be filled by the Assembly as soon as possible; any contracting State so elected

to the Council shall hold office for the unexpired portion of its predecessor's term of office.

(c) No representative of a contracting State on the Council shall be actively associated with the operation of an international air service or financially interested in such a service.

Article 51

President of Council

The Council shall elect its President for a term of three years. He may be reelected. He shall have no vote. The Council shall elect from among its members one or more Vice Presidents who shall retain their right to vote when serving as acting President. The President need not be selected from among the representatives of the members of the Council but, if a representative is elected, his seat shall be deemed vacant and it shall be filled by the State which he represented. The duties of the President shall be to:

(a) Convene meetings of the Council, the Air Transport Committee, and the Air Navigation Commission;

(b) Serve as representative of the Council; and

(c) Carry out on behalf of the Council the functions which the Council assigns to him.

Article 52

Voting in Council

Decisions by the Council shall require approval by a majority of its members. The Council may delegate authority with respect to any particular matter to a committee of its members. Decisions of any committee of the Council may be appealed to the Council by any interested contracting State.

Article 53

Participation without a vote

Any contracting State may participate, without a vote, in the consideration by the Council and by its committees and commissions of any question which especially affects its interests. No member of the Council shall vote in the consideration by the Council of a dispute to which it is a party.

Article 54

Mandatory functions of Council

The Council shall:

(a) Submit annual reports to the Assembly;

(b) Carry out the directions of the Assembly and discharge the duties and obligations which are laid on it by this Convention;

(c) Determine its organization and rules of procedure;

(d) Appoint and define the duties of an Air Transport Committee, which shall be chosen from among the representatives of the members of the Council, and which shall be responsible to it;

(e) Establish an Air Navigation Commission, in accordance with the provisions of Chapter X;

(f) Administer the finances of the Organization in accordance with the provisions of Chapters XII and XV;

(g) Determine the emoluments of the President of the Council;

(h) Appoint a chief executive officer who shall be called the Secretary General, and make provision for the appointment of such other personnel as may be necessary, in accordance with the provisions of Chapter XI;

(i) Request, collect, examine and publish information relating to the advancement of air navigation and the operation of international air services, including information about the costs of operation and particulars of subsidies paid to airlines from public funds;

(j) Report to contracting States any infraction of this Convention, as well as any failure to carry out recommendations or determinations of the Council;

(k) Report to the Assembly any infraction of this Convention where a contracting State has failed to take appropriate action within a reasonable time after notice of the infraction;

(l) Adopt, in accordance with the provisions of Chapter VI of this Convention, international standards and recommended practices; for convenience, designate them as Annexes to this Convention; and notify all contracting States of the action taken;

(m) Consider recommendations of the Air Navigation Commission for amendment of the Annexes and take action in accordance with the provisions of Chapter XX;

(n) Consider any matter relating to the Convention which any contracting State refers to it.

Article 55

The Council may:

Permissive functions of Council

(a) Where appropriate and as experience may show to be desirable, create subordinate air transport commissions on a regional or other basis and define groups of states or airlines with or through which it may deal to facilitate the carrying out of the aims of this Convention;

(b) Delegate to the Air Navigation Commission duties additional to those set forth in the Convention and revoke or modify such delegations of authority at any time;

(c) Conduct research into all aspects of air transport and air navigation which are of international importance, communicate the results of its research to the contracting States, and facilitate the exchange of information between contracting States on air transport and air navigation matters;

(d) Study any matters affecting the organization and operation of international air transport, including the international ownership and operation of international air services on trunk routes, and submit to the Assembly plans in relation thereto;

(e) Investigate, at the request of any contracting State, any situation which may appear to present avoidable obstacles to the development of international air navigation; and, after such investigation, issue such reports as may appear to it desirable.

CHAPTER X

THE AIR NAVIGATION COMMISSION

Article 56

Nomination and appointment of Commission

The Air Navigation Commission shall be composed of twelve members appointed by the Council from among persons nominated by contracting States. These persons shall have suitable qualifications and experience in the science and practice of aeronautics. The Council shall request all contracting States to submit nominations. The President of the Air Navigation Commission shall be appointed by the Council.

Article 57

The Air Navigation Commission shall: Duties of Commission

(a) Consider, and recommend to the Council for adoption, modifications of the Annexes to this Convention;

(b) Establish technical subcommissions on which any contracting State may be represented, if it so desires;

(c) Advise the Council concerning the collection and communication to the contracting States of all information which it considers necessary and useful for the advancement of air navigation.

CHAPTER XI

PERSONNEL

Article 58

Subject to any rules laid down by the Assembly and to the provisions of this Convention, the Council shall determine the method of appointment and of termination of appointment, the training, and the salaries, allowances, and conditions of service of the Secretary General and other personnel of the Organization, and may employ or make use of the services of nationals of any contracting State. Appointment of personnel

Article 59

The President of the Council, the Secretary General, and other personnel shall not seek or receive instructions in regard to the discharge of their responsibilities from any authority external to the Organization. Each contracting State undertakes fully to respect the international character of the responsibilities of the personnel and not to seek to influence any of its nationals in the discharge of their responsibilities. International character of personnel

Article 60

Each contracting State undertakes, so far as possible under its constitutional procedure, to accord to the President of the Council, the Secretary General, and the other personnel of the Organization, the immunities and privileges which are accorded to corresponding personnel of other public international organizations. If a general international agreement on the immunities and privi- Immunities and privileges of personnel

25973 O—58——87

leges of international civil servants is arrived at, the immunities and privileges accorded to the President, the Secretary General, and the other personnel of the Organization shall be the immunities and privileges accorded under that general international agreement.

Chapter XII

FINANCE

Article 61

Budget and apportionment of expenses

The Council shall submit to the Assembly an annual budget, annual statements of accounts and estimates of all receipts and expenditures. The Assembly shall vote the budget with whatever modification it sees fit to prescribe, and, with the exception of assessments under Chapter XV to States consenting thereto, shall apportion the expenses of the Organization among the contracting States on the basis which it shall from time to time determine.

Article 62

Suspension of voting power

The Assembly may suspend the voting power in the Assembly and in the Council of any contracting State that fails to discharge within a reasonable period its financial obligations to the Organization.

Article 63

Expenses of delegations and other representatives

Each contracting State shall bear the expenses of its own delegation to the Assembly and the remuneration, travel, and other expenses of any person whom it appoints to serve on the Council, and of its nominees or representatives on any subsidiary committees or commissions of the Organization.

Chapter XIII

OTHER INTERNATIONAL ARRANGEMENTS

Article 64

Security arrangements

The Organization may, with respect to air matters within its competence directly affecting world security, by vote of the Assembly enter into appropriate arrangements with any general organization set up by the nations of the world to preserve peace.

Article 65

The Council, on behalf of the Organization, may enter into agreements with other international bodies for the maintenance of common services and for common arrangements concerning personnel and, with the approval of the Assembly, may enter into such other arrangements as may facilitate the work of the Organization. **Arrangements with other international bodies**

Article 66

(a) The Organization shall also carry out the functions placed upon it by the International Air Services Transit Agreement and by the International Air Transport Agreement drawn up at Chicago on December 7, 1944, in accordance with the terms and conditions therein set forth. **Functions relating to other agreements**

(b) Members of the Assembly and the Council who have not accepted the International Air Services Transit Agreement or the International Air Transport Agreement drawn up at Chicago on December 7, 1944 shall not have the right to vote on any questions referred to the Assembly or Council under the provisions of the relevant Agreement.

PART III. INTERNATIONAL AIR TRANSPORT

CHAPTER XIV

INFORMATION AND REPORTS

Article 67

Each contracting State undertakes that its international airlines shall, in accordance with requirements laid down by the Council, file with the Council traffic reports, cost statistics and financial statements showing among other things all receipts and the sources thereof. **File reports with Council**

CHAPTER XV

AIRPORTS AND OTHER AIR NAVIGATION FACILITIES

Article 68

Each contracting State may, subject to the provisions of this Convention, designate the route to be followed within its territory by any international air service and the airports which any such service may use. **Designation of routes and airports**

Article 69

Improvement of air navigation facilities

If the Council is of the opinion that the airports or other air navigation facilities, including radio and meteorological services, of a contracting State are not reasonably adequate for the safe, regular, efficient, and economical operation of international air services, present or contemplated, the Council shall consult with the State directly concerned, and other States affected, with a view to finding means by which the situation may be remedied, and may make recommendations for that purpose. No contracting State shall be guilty of an infraction of this Convention if it fails to carry out these recommendations.

Article 70

Financing of air navigation facilities

A contracting State, in the circumstances arising under the provisions of Article 69, may conclude an arrangement with the Council for giving effect to such recommendations. The State may elect to bear all of the costs involved in any such arrangement. If the State does not so elect, the Council may agree, at the request of the State, to provide for all or a portion of the costs.

Article 71

Provision and maintenance of facilities by Council

If a contracting State so requests, the Council may agree to provide, man, maintain, and administer any or all of the airports and other air navigation facilities, including radio and meteorological services, required in its territory for the safe, regular, efficient and economical operation of the international air services of the other contracting States, and may specify just and reasonable charges for the use of the facilities provided.

Article 72

Acquisition or use of land

Where land is needed for facilities financed in whole or in part by the Council at the request of a contracting State, that State shall either provide the land itself, retaining title if it wishes, or facilitate the use of the land by the Council on just and reasonable terms and in accordance with the laws of the State concerned.

Article 73

Expenditure and assessment of funds

Within the limit of the funds which may be made available to it by the Assembly under Chapter XII, the Council may make current expenditures for the purposes

of this Chapter from the general funds of the Organization. The Council shall assess the capital funds required for the purposes of this Chapter in previously agreed proportions over a reasonable period of time to the contracting States consenting thereto whose airlines use the facilities. The Council may also assess to States that consent any working funds that are required.

Article 74

When the Council, at the request of a contracting State, advances funds or provides airports or other facilities in whole or in part, the arrangement may provide, with the consent of that State, for technical assistance in the supervision and operation of the airports and other facilities, and for the payment, from the revenues derived from the operation of the airports and other facilities, of the operating expenses of the airports and the other facilities, and of interest and amortization charges. Technical assistance and utilization of revenues

Article 75

A contracting State may at any time discharge any obligation into which it has entered under Article 70, and take over airports and other facilities which the Council has provided in its territory pursuant to the provisions of Articles 71 and 72, by paying to the Council an amount which in the opinion of the Council is reasonable in the circumstances. If the State considers that the amount fixed by the Council is unreasonable it may appeal to the Assembly against the decision of the Council and the Assembly may confirm or amend the decision of the Council. Taking over of facilities from Council

Article 76

Funds obtained by the Council through reimbursement under Article 75 and from receipts of interest and amortization payments under Article 74 shall, in the case of advances originally financed by States under Article 73, be returned to the States which were originally assessed in the proportion of their assessments, as determined by the Council. Return of funds

CHAPTER XVI

JOINT OPERATING ORGANIZATIONS AND POOLED SERVICES

Article 77

Joint operating organizations permitted

Nothing in this Convention shall prevent two or more contracting States from constituting joint air transport operating organizations or international operating agencies and from pooling their air services on any routes or in any regions, but such organizations or agencies and such pooled services shall be subject to all the provisions of this Convention, including those relating to the registration of agreements with the Council. The Council shall determine in what manner the provisions of this Convention relating to nationality of aircraft shall apply to aircraft operated by international operating agencies.

Article 78

Function of Council

The Council may suggest to contracting States concerned that they form joint organizations to operate air services on any routes or in any regions.

Article 79

Participation in operating organizations

A State may participate in joint operating organizations or in pooling arrangements, either through its government or through an airline company or companies designated by its government. The companies may, at the sole discretion of the State concerned, be state-owned or partly state-owned or privately owned.

PART IV. FINAL PROVISIONS

CHAPTER XVII

OTHER AERONAUTICAL AGREEMENTS AND ARRANGEMENTS

Article 80

Paris and Habana Conventions

Each contracting State undertakes, immediately upon the coming into force of this Convention, to give notice of denunciation of the Convention relating to the Regulation of Aerial Navigation signed at Paris on October 13, 1919 or the Convention on Commercial Aviation signed at Habana on February 20, 1928, if it is a party to either. As between contracting States, this Convention super-

sedes the Conventions of Paris and Habana previously referred to.

Article 81

Registration of existing agreements

All aeronautical agreements which are in existence on the coming into force of this Convention, and which are between a contracting State and any other State or between an airline of a contracting State and any other State or the airline of any other State, shall be forthwith registered with the Council.

Article 82

Abrogation of inconsistent arrangements

The contracting States accept this Convention as abrogating all obligations and understandings between them which are inconsistent with its terms, and undertake not to enter into any such obligations and understandings. A contracting State which, before becoming a member of the Organization has undertaken any obligations toward a non-contracting State or a national of a contracting State or of a non-contracting State inconsistent with the terms of this Convention, shall take immediate steps to procure its release from the obligations. If an airline of any contracting State has entered into any such inconsistent obligations, the State of which it is a national shall use its best efforts to secure their termination forthwith and shall in any event cause them to be terminated as soon as such action can lawfully be taken after the coming into force of this Convention.

Article 83

Registration of new arrangements

Subject to the provisions of the preceding Article, any contracting State may make arrangements not inconsistent with the provisions of this Convention. Any such arrangement shall be forthwith registered with the Council, which shall make it public as soon as possible.

CHAPTER XVIII

DISPUTES AND DEFAULT

Article 84

Settlement of disputes

If any disagreement between two or more contracting States relating to the interpretation or application of this Convention and its Annexes cannot be settled by negotiation, it shall, on the application of any State concerned in the disagreement, be decided by the Council. No

member of the Council shall vote in the consideration by the Council of any dispute to which it is a party. Any contracting State may, subject to Article 85, appeal from the decision of the Council to an *ad hoc* arbitral tribunal agreed upon with the other parties to the dispute or to the Permanent Court of International Justice. Any such appeal shall be notified to the Council within sixty days of receipt of notification of the decision of the Council.

Article 85

Arbitration procedure

If any contracting State party to a dispute in which the decision of the Council is under appeal has not accepted the Statute of the Permanent Court of International Justice and the contracting States parties to the dispute cannot agree on the choice of the arbitral tribunal, each of the contracting States parties to the dispute shall name a single arbitrator who shall name an umpire. If either contracting State party to the dispute fails to name an arbitrator within a period of three months from the date of the appeal, an arbitrator shall be named on behalf of that State by the President of the Council from a list of qualified and available persons maintained by the Council. If, within thirty days, the arbitrators cannot agree on an umpire, the President of the Council shall designate an umpire from the list previously referred to. The arbitrators and the umpire shall then jointly constitute an arbitral tribunal. Any arbitral tribunal established under this or the preceding Article shall settle its own procedure and give its decisions by majority vote, provided that the Council may determine procedural questions in the event of any delay which in the opinion of the Council is excessive.

Article 86

Appeals

Unless the Council decides otherwise, any decision by the Council on whether an international airline is operating in conformity with the provisions of this Convention shall remain in effect unless reversed on appeal. On any other matter, decisions of the Council shall, if appealed from, be suspended until the appeal is decided. The decisions of the Permanent Court of International Justice and of an arbitral tribunal shall be final and binding.

Article 87 .

Each contracting State undertakes not to allow the operation of an airline of a contracting State through the airspace above its territory if the Council has decided that the airline concerned is not conforming to a final decision rendered in accordance with the previous Article.

Penalty for non-conformity of airline

Article 88

The Assembly shall suspend the voting power in the Assembly and in the Council of any contracting State that is found in default under the provisions of this Chapter.

Penalty for non-conformity by State

CHAPTER XIX

WAR

Article 89

In case of war, the provisions of this Convention shall not affect the freedom of action of any of the contracting States affected, whether as belligerents or as neutrals. The same principle shall apply in the case of any contracting State which declares a state of national emergency and notifies the fact to the Council.

War and emergency conditions

CHAPTER XX

ANNEXES

Article 90

(a) The adoption by the Council of the Annexes described in Article 54, subparagraph (1), shall require the vote of two-thirds of the Council at a meeting called for that purpose and shall then be submitted by the Council to each contracting State. Any such Annex or any amendment of an Annex shall become effective within three months after its submission to the contracting States or at the end of such longer period of time as the Council may prescribe, unless in the meantime a majority of the contracting States register their disapproval with the Council.

Adoption and amendment of Annexes

(b) The Council shall immediately notify all contracting States of the coming into force of any Annex or amendment thereto.

Chapter XXI

RATIFICATIONS, ADHERENCES, AMENDMENTS, AND DENUNCIATIONS

Article 91

Ratification of Convention

(a) This Convention shall be subject to ratification by the signatory States. The instruments of ratification shall be deposited in the archives of the Government of the United States of America, which shall give notice of the date of the deposit to each of the signatory and adhering States.

(b) As soon as this Convention has been ratified or adhered to by twenty-six States it shall come into force between them on the thirtieth day after deposit of the twenty-sixth instrument. It shall come into force for each State ratifying thereafter on the thirtieth day after the deposit of its instrument of ratification.

(c) It shall be the duty of the Government of the United States of America to notify the government of each of the signatory and adhering States of the date on which this Convention comes into force.

Article 92

Adherence to Convention

(a) This Convention shall be open for adherence by members of the United Nations and States associated with them, and States which remained neutral during the present world conflict.

(b) Adherence shall be effected by a notification addressed to the Government of the United States of America and shall take effect as from the thirtieth day from the receipt of the notification by the Government of the United States of America, which shall notify all the contracting States.

Article 93

Admission of other States

States other than those provided for in Articles 91 and 92(a) may, subject to approval by any general international organization set up by the nations of the world to preserve peace, be admitted to participation in this Convention by means of a four-fifths vote of the Assembly and on such conditions as the Assembly may prescribe: provided that in each case the assent of any State invaded or attacked during the present war by the State seeking admission shall be necessary.

Article 94

(a) Any proposed amendment to this Convention must be approved by a two-thirds vote of the Assembly and shall then come into force in respect of States which have ratified such amendment when ratified by the number of contracting States specified by the Assembly. The number so specified shall not be less than two-thirds of the total number of contracting States.

Amendment of Convention

(b) If in its opinion the amendment is of such a nature as to justify this course, the Assembly in its resolution recommending adoption may provide that any State which has not ratified within a specified period after the amendment has come into force shall thereupon cease to be a member of the Organization and a party to the Convention.

Article 95

(a) Any contracting State may give notice of denunciation of this Convention three years after its coming into effect by notification addressed to the Government of the United States of America, which shall at once inform each of the contracting States.

Denunciation of Convention

(b) Denunciation shall take effect one year from the date of the receipt of the notification and shall operate only as regards the State effecting the denunciation.

Chapter XXII

DEFINITIONS

Article 96

For the purpose of this Convention the expression:

(a) "Air service" means any scheduled air service performed by aircraft for the public transport of passengers, mail or cargo.

(b) "International air service" means an air service which passes through the air space over the territory of more than one State.

(c) "Airline" means any air transport enterprise offering or operating an international air service.

(d) "Stop for non-traffic purposes" means a landing for any purpose other than taking on or discharging passengers, cargo or mail.

ANNEXES TO THE CONVENTION

1. Personnel licensing	Licensing of operating and maintenance personnel.
2 Rules of the air	Rules relating to visual and instrument flight.
3. Meteorology	Codes, meteorological communications, and meteorological services
4. Aeronautical charts	Standardization of charts for use in international aviation
5 Dimensional units to be used in air-ground communications.	Reduction in the variety of dimensional systems.
6 Operation of aircraft international commercial air services	Specifications which will insure in similar operations throughout the world a level of safety above a prescribed minimum.
7. Aircraft nationality and registration marks	Requirements for registration and identification of aircraft.
8 Airworthiness of aircraft	Certification and inspection of aircraft according to uniform procedures.
9. Facilitation	Simplification of the formalities involved in moving an aircraft, its passengers, and its cargo across international boundaries.
10. Aeronautical telecommunications.	Standardization of communications systems and radio air navigation aids.
11. Air traffic services	Establishment and operation of air traffic control, flight information, and alerting services.
12 Search and rescue	Organization of facilities and services necessary for search and rescue.
13 Aircraft accident inquiry	Uniformity in the notification, investigation of, and reporting on aircraft accidents.
14. Aerodromes	Characteristics and equipment for aerodromes used in international navigation.
15. Aeronautical information services	Uniformity in methods of collection and dissemination of aeronautical information

(Whereupon, at 1:30 p m., the committee adjourned to reconvene at 2:30 of the same day.)

AFTERNOON SESSION

(The committee reconvened at 2:38 p. m., Hon. John W. McCormack, presiding.)

The CHAIRMAN. The first witness will be our former colleague and friend, the Honorable Harris Ellsworth, Chairman of the Civil Service Commission. Harris, we are glad to see you here and welcome you back among us.

STATEMENT OF HARRIS ELLSWORTH,[40] CHAIRMAN, UNITED STATES CIVIL SERVICE COMMISSION; ACCOMPANIED BY WARREN B. IRONS, EXECUTIVE DIRECTOR, UNITED STATES CIVIL SERVICE COMMISSION

Mr. ELLSWORTH. Thank you, John. It is a pleasure to be up here before this great committee. I hope I can contribute something worthwhile.

I have a rather brief statement, Mr. Chairman.

I appreciate being given the opportunity to comment before this committee on H. R. 11881, establishing the National Aeronautics and Space Agency. This is indeed a fast-moving age. When I was a Member of the Congress, I did not have the opportunity to consider legislation for such a thought-provoking subject as research into problems of flight within and outside the earth's atmosphere

My special concern, and I am sure your interest in my testimony, bears on section 6 (b) (2) of the bill which exempts the new Agency from the Classification Act of 1949 and the Federal Employees Pay Act.

It gives the proposed NASA authority to—

> fix and adjust, as nearly as consistent with the public interest and on the basis of equal pay for equal work at rates which are reasonably comparable with prevailing rates paid by non-Federal employers for similar work, compensation of such officers and employees as may be necessary to carry out the provisions of this Act.

This authority would be subject to such regulations as the President might prescribe.

I am sure that you have already been presented with ample evidence of the special and critical requirements of this most important activity to attract and retain the country's most outstanding personnel in order to continue and expand the research activity in this vital area When considering the personnel problems involved in staffing the agency which H. R. 11881 would create, two important and compelling facts must be borne in mind.

First, this Agency occupies a position of the highest possible importance in Government operations and will deal with some problems the solution of which lie as yet outside the knowledge and experience of man.

Second, there is a decided element of urgency in the mission of this proposed Agency—certainly this Agency must function with speed, accuracy, and efficiency, and must be as free from staffing problems and personnel difficulties as possible.

In view of these facts the NASA must be able to adjust promptly and adequately to competitive salary rates in order to maintain an adequate and qualified work force for the support of this important mission.

---

The proposed pay provisions in this bill are intended to meet this need for timely and adequate pay adjustment. These provisions include at least two desirable restrictions. One calls for a welding of the principle of equal pay for equal work with the principle of reasonable comparability with prevailing pay. This will effectively guard internal job and pay alinement against undesirable dislocations.

The other requires that this authority be exercised under regulations prescribed by the President. This will assure that this authority will be exercised subject to externally imposed standards, and I believe we may presume that such standards will require the administration of this authority to be geared properly with relevant existing practices and procedures of pay fixing in the Government.

For example, it is my understanding the Agency, even though exempt from the position classification provisions of the Classification Act, will nevertheless continue to classify its jobs in a manner fully consistent with job classification under the act, so that there will be no obscurity as to occupational classification and grade level allocation as between the positions in the NASA and positions which are subject to the Classification Act.

Moreover, it is my understanding that no additional organization will be established by this Agency to obtain the necessary field data on pay rates paid by non-Federal employers but instead will be able to rely on existing data collection organizations.

The principle of fixing rates of pay which compare reasonably with current compensation of non-Federal employees engaged in broadly comparable work is not new. I understand the NACA currently has nearly half its employees already compensated under a prevailing rate system with which it has had many years of experience.

This experience augurs well for the successful extension of this principle to the additional categories of positions which this legislation will authorize. The agency in all respects except pay, that is to say except for the exemption from the Classification Act and the Federal Employees' Pay Act of 1945, will be subject to all of the civil service and personnel control laws which presently apply to the NACA.

In view of the special circumstances of this new Space Agency I am convinced that special provisions for the establishment of pay rates such as have been proposed are fully warranted. With the emphasis that has been given to the principles of equal pay for equal work and other controlling principles we are confident that this pay plan can operate successfully. This departure from the somewhat traditional rigid provisions of the Classification Act pay structure is wholly justified and should permit the needed flexibility and responsiveness to prevailing pay practices which will be so essential for the successful operation of this uniquely new program.

I do not wish to imply that adoption of the proposal for NASA will solve the problems of other agencies. The Congress may soon have to face the problems of other agencies engaged in critical developmental activities such as the great research enterprises in the Department of Defense and many of those in other long-established agencies which do not have the proposed authority.

It has seemed to me for some time that the way in which the Government establishes the rates of pay for most of its white-collar workers is antiquated and hardly compatible with this space age. The

efforts to meet the Government's salary needs by the establishment of rigid statutory pay scales for Classification Act and postal employees, and the difficulties that this imposes upon both the legislative and executive branches are very well known.

The pay system proposed in H. R. 11881 represents a different approach than heretofore made toward a relief from the difficulties and headaches connected with the present basis of setting most Government salaries by statute. Even though in itself this experiment may create new and different personnel management headaches it would seem to be a step worth taking; an experiment that should be made and, which I might add, being experimental, is quite in keeping with other objectives of this proposed legislation.

I am convinced that the authority proposed for NASA in section 6 (b) (2) of H. R. 11881 will provide a pilot operation in the personnel field which may help materially our efforts to develop a better way of setting salaries.

I urge its adoption.

That concludes my statement, Mr. Chairman.

The CHAIRMAN. Mr. Ellsworth, on page 4, the second paragraph of your statement, you present a troublesome question that confronts some of the members of the committee.

I am for the provision of the bill contained on page 6, but what concerns me is what will be its relative effect elsewhere upon those scientists and technicians in other departments and agencies who are under, or who are subject to the Classification Act?

Mr. ELLSWORTH. Well, I think, Mr. Chairman, that the effect would be rather more in a morale way than actual. Because I am told by the NASA people—or I mean the NACA people—informally that this new Agency would probably not involve the employment of more than 200 more people.

In other words, an infinitesimal number compared with the Government as a whole.

So I doubt that this provision would actually set up anything in the way of competition as between this new Agency and the other important agencies.

However, there will be that feeling, I think, and it is only natural, because it exists with respect to the other excepted services to some extent, that these Agency people are better treated than the ones in the other agencies.

It doesn't necessarily follow that that is true. But there will be that thought, I think.

The CHAIRMAN. Will the provisions of paragraph 2 of section 6 cover all of the employees of this new Agency when established?

Mr. ELLSWORTH. It is my understanding that it does.

The CHAIRMAN. Clerical help and all others?

Mr. ELLSWORTH. Yes. It covers all employees of the Agency.

The CHAIRMAN. Of course, from the angle of relative effect, if a scientist or technician working in the Defense Department under the Classification Act, whose salary is less than what one of the same positions that would be under this Agency—and you can include other agencies where scientists and technicians are employed—I am wondering how he would feel under those circumstances.

Mr. ELLSWORTH. Well, Mr. Chairman, that is one of the minor risks. I should point out that there is another situation in Public Law 313 which gives to five agencies presently the——

The CHAIRMAN What is that citation?

Mr ELLSWORTH. Public Law 313.

Mr FULTON. What year?

Mr ELLSWORTH. We will have to furnish you the precise citation. I don't have it here

In the parlance of the trade, so to speak, we refer to these positions as 313 positions. That law allows the five agencies which have the benefit of it to employ people in scientific—employ people in research and development fields, I believe it is.

It is narrowly defined. Employ them at salaries ranging from $12,500 up to $19,000, on the basis of the individual.

In other words, they have to send to the Commission the qualification statement for the individual and the proposed salary. And then our technical people examine the qualifications and see if the request is otherwise in order

Now, that is really a very similar thing to this under a different name.

The CHAIRMAN. You can see the matter that concerns me. I would go right across the board. But we don't have the jurisdictional authority to do that. That is a matter which should come before the Committee on Post Office and Civil Service. But that is a matter of concern.

The provisions themselves don't concern me. But I then ask, what will be the effect of unintentional inequity on others?

Mr. ELLSWORTH. As I pointed out in my prepared statement, we at the Commission, are aware that big Government having come to stay, something should be done legislatively to change the present basis for setting rates of pay by statute.

I think we are seeing at this moment the problems that are involved in the present way of doing it.

The pay bills have been pending now in the Congress for two sessions, a lot of time being used in debate on them, with the possibility that there will have to be more discussion of the same subject next year.

I mean that is a possibility. We think that there must be a more practical and more efficient way of doing it.

So this may point a way in that direction.

The CHAIRMAN. You say the other five agencies have the authority on individual cases to go ahead——

Mr. ELLSWORTH They have very limited authority. I think with reference to defense itself the number probably is 25. I think the Department of Agriculture is allowed five of these appointments. The Institute of Public Health is allowed a certain number. They are all by statute

In other words, only five agencies have this authority. And none of the five have any more than just a few that they may allocate in this category

However, it is a precedent and it is a principle presently in use.

The CHAIRMAN. But this would be a precedent over that. You say it would cover employees in the clerical status, for instance. Suppose this provision went through. What could this Agency do in connection with their salary, subject to such regulations as the President may prescribe, without regard to the Classification Act of 1949 as amended?

Mr. ELLSWORTH. Well, it is still to be determined, of course. I would assume that the regulations and grade lists and salaries set up by the new Agency under this new authority would follow the Bureau of Labor figures and the prevailing rates in the various communities where they operate. I think that is what is intended by the section.

The CHAIRMAN. Of course in the Navy Department you have some such situation existing in relation to certain employees in connection with the prevailing wages as it applies to industry. But this is different than that, I think. Isn't it?

Mr. ELLSWORTH. A third of the employees of Government, about 750,000, are now working under the prevailing rate plan, under what we call the wage board or blue-collar principle. They are now limited to crafts, trades, and common labor. Their rates of pay, their hourly rates generally, are set by local boards on the basis of surveys conducted locally. They represent about a third of all the workers in the Government.

In NACA presently are employed 3,535 of these prevailing rate blue-collar employees, and 4,230 of their employees are under the Classification Act. So the NACA has considerable experience with the prevailing rate type of employment.

The CHAIRMAN. You say the pay system proposed in H. R. 11881 represents a different approach than heretofore made to afford relief from the difficulties and headaches connected with the present basis of setting most governmental salaries by statute.

So, for this agency we have an entirely different approach than the rest of the governmental agencies, with the possible exception of these isolated cases you have mentioned on a case-to-case or individual-to individual basis in the field of science and technology.

Mr. ELLSWORTH. It is a different kind of exception. Now, we have, I think, about 40 different pay systems in Government; 40 different other exceptions to the terms of the Classification Act.

This, however—this approach is different from any of the other 40, and the reason that I have—or one of the main reasons why I have testified in favor of it is that this is the first time, if this is enacted, wherein what we call white collar or classification type people will be employed under a prevailing rate pay system.

And as I said in my statement, it is something that we think probably is well worth trying. It has never been done before.

The CHAIRMAN. You say under the present rate of pay system the words—

> on the basis of equal pay for equal work at rates which are equally comparable to the prevailing rates paid by non-Federal employees for similar work

Well, under this your stenographic employees might get a reduction in salary.

Mr. ELLSWORTH. That could be possible.

The CHAIRMAN. Now, many of your clerical help could get a reduciton in salary.

Mr. ELLSWORTH. This gives the agency complete freedom under the rules set up.

The CHAIRMAN. But they have to do it on the basis of equal pay for equal work at rates which are reasonably comparable with prevailing rates paid to non-Federal employees of similar work. They have got to comply with those provisions?

Mr. ELLSWORTH. Yes. The reference is to the competition with industry or with non-Federal employment in the different areas.

The CHAIRMAN. Taking the city of Washington, are the stenographers in Government paid more than those in nongovernment service?

Mr. ELLSWORTH. I don't know.

The CHAIRMAN. I should think they would be.

Mr. ELLSWORTH. The rates for the same job are the same the Nation over. But I wouldn't be surprised but what in some communities a grade 3 typist is probably paid more than a similar typist in non-Federal employment. But I am sure there are other places where she is not paid as much.

A nationwide statutory salary does have some inequities in it, no matter what we do. That is one reason we are interested in this experiment; to see if there is a better way.

The CHAIRMAN. Well, of course we are confining it to this agency. But you have indicated it might well be a pattern for a good part of the Government. And then you have got to project your mind and see what the results of that might be.

Mr. ELLSWORTH. My own thinking on that is that it may give us—if this is enacted and this agency does operate under this section, that it will give us some awfully useful field data on which a broader plan or policy could be set up.

At the present time we don't actually have any pilot or experimental data on which to base a proposed change. I think that is one of the reasons why we haven't come up with a suggestion for a better system.

The CHAIRMAN. I know. But we are going to have a fundamental change like that. You have been a Member of Congress for years, and you know the jurisdiction of committees. Don't you think that is a matter that should be taken up with the proper committees, such as the Post Office and Civil Service?

Mr. ELLSWORTH. That is right.

The CHAIRMAN. And if we were to report this provision out, much as I might be impressed with it, I refer to my previous statement in connection with scientists and technicians—the technical men. I hadn't thought of the clerical and stenographic force until I asked you the question that they might even get a reduced salary under this.

Mr. ELLSWORTH. Well, you can't tell. It just depends on what their survey reveals.

The CHAIRMAN. But nobody wants that.

Mr. ELLSWORTH. Actually my thinking with reference to the subject generally is in the broad sense. And obviously that should go to the legislative committees. This is an exceptional thing, and it is something that is brandnew. I think your committee has every right in this case to specify just exactly how it should be done.

The CHAIRMAN. Of course, we are making really a fundamental change. And it is not something that is sort of an experiment to determine whether it should be applicable right across the board.

Mr. ELLSWORTH. We could find out—if this is done, just how it does work in actual practice.

The CHAIRMAN. You say that there are provisions of law where in other agencies they can, on an individual case, take up with the Civil Service Commission and with the approval of the Civil Service Com-

mission bring about a result which is, in effect, a waiver of the Classification Act—pay a higher wage?

Mr. Ellsworth. That is right.

Those are for technical people.

The Chairman. I assumed that this is intended more or less for technical people.

Mr. Ellsworth. Of course that authority we are speaking of now, that 313 authority, doesn't go to typists or jobs of that kind. They are a very narrowly defined group of people.

The Chairman. I doubt that the many tens of thousands of persons employed in clerical positions, stenographic positions, in the postal service and all other services—I don't know how they would feel about this, because it is really a fundamental change while confined to one agency.

When I was asking you about the relativity, I was confining it to scientists and technicians and by "technicians" I mean scientists in the applied sense, and others in the technical field. But this was intended to enable the government agencies to keep those men and to induce them to stay on.

But this legislation might give them a preferential status where they might go out and raid other agencies. Not that they would, but the situation would exist where scientists and others who come under this provision might seek to get into this new agency because of the higher salary.

Mr. Ellsworth. They might. But as I pointed out earlier it isn't likely this agency is going to be very competitive with any other agency, because it is already in business, and they don't expect to hire very many more.

The Chairman. There must be some incentive for them to have this provision—it must be a competitiveness between the other agencies—that is, the move on the part of the agency to try to keep men in the service of the agency.

Although the scientists and technicians may not get as much as a private employer might give them, there are many dedicated men in the country.

Yet, on the other hand even dedicated people have to consider the economic situation for themselves and their families. We all have to. That is a natural, legitimate, selfish consideration—justifiably selfish; not unjustifiable. It is consistent with theology—justifiable selfishness.

Would you submit to the committee the language of the 313, so that the committee might consider it?

Mr. Ellsworth. Yes.

The Chairman. And in connection with the technicians, I am not saying how I would vote on it, but I see these dangers. And I see a bill that has a very desirable objective getting on the floor. It might get tangled up in that jurisdictional dispute. And other groups of Federal employees might get alarmed at it. And I couldn't criticize them. I am not prepared to say whether I could criticize them.

But I wouldn't want to have a bill, with such desirable and necessary objectives, become tied up in a journey through Congress by something that is really minor in its nature and which should be approached from a broader angle.

Mr. ELLSWORTH. We will be glad to supply the information requested.

The CHAIRMAN. I would like to have you submit it on 313. . And if in connection with scientists and technicians you can liberalize 313 to this agency so far as the Civil Service is concerned, it would be appreciated.

I never thought for an instance that this was intended to go into the clerical element, what might be termed "clerical help." I can see under that——

Mr. ELLSWORTH. It applies to all——

The CHAIRMAN. It might reduce the salary.

Mr. ELLSWORTH. The terms of the section do apply to all employees of the agency.

The CHAIRMAN. You have been very helpful. Other members of the committee will ask you questions.

But this particular paragraph of the bill is what concerns me in its relationship to other agencies. And our other colloquy has come from additional information that I was not consciously aware of.

Mr. ELLSWORTH. We think of it as a very interesting and rather useful proposal.

Mr. McDONOUGH. Would the chairman yield at that point.

The CHAIRMAN. Yes.

Mr. McDONOUGH. Could that be overcome by a minimum wage under a specification for the type of position?

Now, I can anticipate the white collar employee and some of the blue collar employees in this agency being employed for a minimum wage and for a specific reason because they have a certain capability. And if the specification were written and the minimum wage rate, there would be no reduction.

Mr. ELLSWORTH. I am going to ask Mr Irons to respond to that. He is the Executive Director of the Commission.

Mr. IRONS. This provision of course would apply with a prospective hiring primarily, not to people on the rolls at the present time. If we had a Classification Act person on the rolls, his current rate would be protected by existing law; no special language is needed for that purpose

The CHAIRMAN. But supposing somebody is hired after this bill becomes effective, and he is hired as a clerical employee, and he gets less salary than somebody else in the same position.

Mr. IRONS I would think that would present an interesting problem moralewise for the agency.

The CHAIRMAN. It could be, under this.

Mr. IRONS We will be glad to supply the language on the Public Law 313. We will have it up here tomorrow morning.

The CHAIRMAN. Mr. Hays.

Mr. HAYS. I have no questions. I do want to say to our old friend and colleague that we are delighted to have him here and I am glad he can cross over that bridge that separates the legislative and executive department.

Mr. ELLSWORTH. Thank you.

Mr. HAYS. I am pleased to know that you attach a great deal of importance to personnel standards in this procedure.

Mr. ELLSWORTH. It is fundamental I think in our whole personnel-management problem.

Mr. HAYS. Thank you.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. I have no questions. But I want to join with you in thanking our former colleague, Mr. Ellsworth, for his appearance.

Mr. SISK. I think all the questions I had were brought out.

Mr. McDONOUGH. I just want to greet my former colleague. I appreciate your point of agreeing with the committee that this is a specialized agency and does require special treatment.

Mr. ELLSWORTH. Nothing like this has ever been contemplated before. And I think it is entitled to have that type of consideration by Congress.

The CHAIRMAN. Have you consulted with the Civil Service Commission?

Mr. ELLSWORTH. We consulted.

The CHAIRMAN. Were you in on the actual drafting?

Mr. ELLSWORTH. I don't know whether we had any part of setting up the words or not. But we knew what was being put in it.

The CHAIRMAN. Mr. Fulton.

Mr. FULTON. No questions. We are glad to have you here. I think you have given an excellent statement. I think that some of your words should be pointed out especially, because I think they are particularly appropriate in this time when the country and Congress is looking which way to go.

You have said:

> Ample evidence of the special and critical requirements of this most important activity.

And further:

> To attract and retain the country's most outstanding personnel in order to continue and expand the research activity in this vital area.

I like those statements very much.

On page 2 you have also stated very well—

> Secondly, there is a decided element of urgency in the mission of this proposed agency. Certainly this agency must function with speed, accuracy, and efficiency and must be as free from staffing problems and personnel difficulties as possible.

I agree with those thoroughly and believe that we are in a vast new field, that we should keep our minds open and be willing, in Congress, to meet the challenges as they come up.

Thank you, very much.

Mr. ELLSWORTH. Thank you.

The CHAIRMAN. Mr. Ford?

Mr. FORD. Mr. Chairman, our former colleague has presented a very fine justification, I think, of the proposed provision. I think you have covered the points where there might be some area of modification, perhaps. We are glad to have Mr. Ellsworth with us on this occasion. That is all, Mr. Chairman.

The CHAIRMAN. Mr. Feldman? Mr. Feldman is our director and general counsel, Harris.

Mr. FELDMAN. In addressing ourselves to this particular section, I see no ceiling in here; no limitation of any kind on wages.

Mr. ELLSWORTH. The limitation in the section, of course, is the prevailing rate of the competition—the reasonable competition of non-Federal employment, I think.

Mr. FELDMAN. How do you envisage that that will be determined?

Mr. ELLSWORTH. I don't know that any actual plan has been made on it. But I think it was assumed in discussing it in the preliminary stages that the Bureau of Labor Statistics service would probably be used.

Mr. IRONS. If I might answer that a little more specifically. It is my understanding of the preliminary thinking on the plans, if this section is passed by Congress, that the NASA would request the Bureau of Labor Statistics to conduct rate studies in the various localities and nationwide for the occupations and professions in which they are interested. In turn, based upon that information, the Director of the NASA would make such recommendations to the President or whatever agency is designated by the President as to what he thinks the rate should be based upon the prevailing rate data.

Also that the Director of the NASA would make certain that the various positions in NASA would be related to like positions under the Classification Act.

Mr. FELDMAN. That is the modus operandi.

Mr. IRONS. That is the plan of thinking.

Mr. FELDMAN. The modus operandi.

Mr. IRONS. That is correct.

Mr. FELDMAN. Could that be narrowed so that in the case of a dispute the President could look to the Civil Service Commission for its views on the subject?

Mr. IRONS. It is my understanding at this time that no decision has been made yet as to what agency of the Government the President would rely for disputes of that nature and for determining whether the Director of NASA was carrying out his responsibilities correctly.

It would be my judgment—and I will admit that I have a certain bias in this direction—that the logical agency to perform that function would be the Civil Service Commission.

We have the know-how in this particular field.

Mr. FELDMAN. And if this provision were amended in that connection, would that not be a similar safeguard?

Mr. IRONS. I don't know the legal niceities of having the legislation direct that the President shall issue regulations, or propose that the President shall designate the Civil Service Commission as the agency. I don't know that it is customary to have the President's hands tied to that extent in legislation.

Mr. FELDMAN. It could be a way, though, of curing the situation.

Mr. IRONS. Yes.

Mr. FELDMAN. Now, getting back to Public Law 313——

Mr. ELLSWORTH. I think I should point out that that illustration isn't really on point with this section. I merely used it in my comments to indicate that there had been, and is now existing——

Mr. FELDMAN. There is a technique, in other words, and the technique is found in Public Law 313.

Mr. ELLSWORTH. In general, that is correct, yes.

Mr. FELDMAN. And there may be some language in 313, again, that would be helpful in nailing down this provision and making it a lot more specific than it is at the present time. This would seem to give a great deal of latitude to fix wages at almost any scale manageable.

Mr. ELLSWORTH. There would be very definite limitations. I mean the section itself——

The CHAIRMAN. Is NACA now covered by 313?

Mr. ELLSWORTH. Yes.

It permits the employment of a particular specialist, a particular scientist or particular engineer wanted very badly by a particular agency. And this allows them that—this allows that agency up to $19,000, based upon the qualifications that he has to hire him and present to the Commission the reasons for doing it.

The CHAIRMAN. Has there been much difficulty in having the approval made by the Civil Service Commission?

Mr. ELLSWORTH. No. In general the qualification of such people has been very high——

The CHAIRMAN. It has to be somebody who is not only a scientist but particularly specialized.

Mr. IRONS. It is professional and scientific, I believe, are the terms. It has to be in research areas. And the individuals are unusually well qualified for the particular assignment. The man is related to the job.

Mr. FORD. May I ask a question, Mr. Chairman?

The CHAIRMAN. Certainly.

Mr. FORD. Under 313 and under this provision, if Congress subsequently passed legislation increasing wages for Government employees, would the people covered by this section and by 313 get a comparable automatic increase; or would their increases come by administrative action subsequently?

Mr. ELLSWORTH. Well, with reference only to 313, their increases would come only by requests from the agency to adjust their salaries.

Mr. FORD. Would the same apply to the proposed provisions?

Mr. ELLSWORTH. Under this, they would work out their own—it would be based on equal rates—as it says:

> Equal pay for equal work at rates which are reasonably comparable with prevailing rates.

That would be their authority. I want to again point out with reference to this 313, it is a very limited category and for a very specific purpose. I doubt that there would be any basis of actual interpolation of that, with this—NASA.

The CHAIRMAN. But anything we do might have an effect on agencies employing 313 employees?

Mr. ELLSWORTH. Not very much.

The CHAIRMAN. Well, I know. But there is a law of relativity that applies.

Harris, suppose there is a scientist in the Defense Department, and he is getting, say, $14,000 a year. And, under this a man of similar position and comparable ability in the NASA gets, by reason of the operation of these provisions, gets $16,500 or $17,000. That could happen, couldn't it?

What would be the views of the fellow in the Defense Department or in some other agency doing research work?

Mr. ELLSWORTH. As I said earlier, there would be a morale problem there.

It actually wouldn't be practical for the people, say, in the Defense Department to move over to the other agency, because they wouldn't need them. But nevertheless there would be that disparity, certainly.

The CHAIRMAN. In the field of scientific and technical positions, I can understand it. It may be that the equal pay for equal work might well be across the board. I don't know.

I am not passing on that.

Now, we know that in the Navy Department certain employees—mechanical and others—are subject to a law like that. And as I understand it, their pay is determined by what is paid in private employment within a reasonable area.

Mr. ELLSWORTH. That is correct.

The CHAIRMAN. Under this NASA, there is no agency. They have boards appointed. They look into it very thoroughly. I know many times the employees claim that they are not getting an increase that is comparable—equal pay.

You would have to have a board for Washington and a board for wherever they were.

Mr. IRONS. It could be on a national prevailing rate pattern, either one.

Mr. FELDMAN. The Bureau of Labor Statistics Index.

Mr. IRONS. That is right.

The CHAIRMAN. The rate of pay, say, in a laboratory out West might be different from a rate of pay in the central office in Washington

Mr. ELLSWORTH. That is quite right.

The CHAIRMAN. Now, they are all at the same salary.

Mr. IRONS. They all get the same salary now. This law as I read it would permit rates to be determined on a local prevailing rate basis or on a national prevailing rate basis; for some provisions locally.

The CHAIRMAN I ask that you draw up language based on 313. I find now in asking you some questions that that is confined to employees who are needed for a specialized position, although there may be others who are capable of doing it.

Mr. IRONS. It is very narrow.

The CHAIRMAN. I can see there where there might be the necessity for a little broadening. Would you draw up language based on 313 and a little broader language confining it to what you might call the scientific staff—scientific employees, technicians. Do you understand what I mean?

Mr. IRONS. Yes.

The CHAIRMAN. In other words here we can go beyond 313 and yet not put through a fundamental change for this Agency in the salary set up for the classified Government employees.

Mr. IRONS. Congressman, could I ask a question right now?

Who on your committee should we contact if we need to ask further questions?

The CHAIRMAN. Mr. Feldman.

Mr. IRONS. Fine. Thank you.

The CHAIRMAN. Any further questions?

Mr FELDMAN. Yes; I have one question.

The CHAIRMAN. Mr. Feldman.

Mr. FELDMAN. The purpose of this provision in the legislation is primarily to enable the new Agency to compete with private industry in hiring scientists and research people; is that not so?

Mr. ELLSWORTH. That is correct. I think it might go even farther than that I think they have in mind that when they start in to do something they don't want to be hampered, they want to be able to go and get the employees they want and put them to work.

Mr. FELDMAN. That is true, but I am talking about research people and scientific people. And there is testimony before this committee that all relate to that one group—in other words, the group that you say are paid a wage scale ranging between $12,000 and $19,000 a year.

Now, if this provision were restricted to that category and the rest subject to the usual civil service classification law, might that not meet the objective of those behind this legislation?

Mr. ELLSWORTH. I am not quite certain about that. What you would have then would be three different pay systems in the single Agency. You would have the wage board, the blue-collar people, about 3,500 of them already work for NACA. Then you would have the Classification Act, ordinary employees such as the clerks, typists, and supervisors. Then you would have your professional prevailing rate type of group as a third category.

Mr. FELDMAN. This new provision, which would only apply to new employees; might you not be in the situation of where a scientist would be employed who would receive a higher wage than another scientist who was already on the payroll?

Mr. IRONS. I wouldn't think so. I would think the Agency would adjust the salaries within the Agency so that they would be comparable.

Mr. FELDMAN. But you say that wouldn't apply; this particular provision wouldn't apply to those already employed.

The CHAIRMAN. As I understood it, Mr. Ford asked in case the pay-raise bill went through, would the employees benefit. You answered "no." Is that right?

Mr. IRONS. If this were law the people employed under this law would look to this law for any improvement or ——

Mr. FELDMAN. Well the language in the act says, "To select, appoint, employ, and subject to such regulations as the President may prescribe."

That "to select, appoint, and employ"—does that mean people already employed or new people?

Mr. IRONS. I would think that would mean new people to NASA.

The CHAIRMAN. That means their appointment would have to be subject to the civil-service law for examination, certification, veterans' rights, and so forth. In other words, the appointment would have to be in accordance with the civil-service law or transfers from one agency to another.

Mr. IRONS. That is the way I understand it, yes.

Mr. FELDMAN. I am directing myself to another situation. The new agency is going to take over the NACA. You stated before that this provision would not be applicable to NACA but that they would get the wage scale that they are presently obtaining; is that not so?

They have 7,600 employees or around that number. This does not affect them

Mr. IRONS. This does not affect the employees of NACA, as I see it. When NASA comes into existence, NASA would take over, I would presume, employees of NACA, the existing agency.

Mr. FELDMAN. Would they be new employees within the terms of this legislation?

Mr. IRONS. Yes.

Mr. FELDMAN. Then they would be reclassified based on this provision; all of the NASA employees?

Mr. IRONS. That is the way I would interpret this; yes.

Mr. FELDMAN. Well, that isn't the way it was explained to us in the report.

Mr. IRONS. That is the way I interpret it. I may be wrong about that.

Mr. FELDMAN. Wouldn't the objective of the provision be met if you limit this provision to apply to people engaged in scientific and research work?

Mr. IRONS. What kind of people? You mean scientific?

Mr. FELDMAN. I am talking about scientists.

Mr. IRONS. That is the Public Law 313 type of individual.

Mr. FELDMAN. That is right; just confined to those particular people. Would not the objectives of this law and the reason for this provision, in other words, be fulfilled?

Mr. IRONS. As I interpret this provision it goes far beyond that.

Mr. FELDMAN. Yes, it does. We are getting into a brand new field.

Mr. IRONS. I won't argue that with you, but I think the objective of this legislation was to give, within the limitations written here, the broadest possible authority to the Director of this new Agency to recruit and retain all kinds of people, not just research people.

Mr. FELDMAN. Then it becomes an experiment, as you say, in connection with other phases. And don't you think that that kind of legislation belongs before another committee of the Congress?

Mr. ELLSWORTH. My own feeling is that as an experimental proposition this is relatively small. And this committee could report this bill out with this provision in it on that basis; that it is something new, unusual, more or less a crash-program idea, and that this is needed to make it go.

Mr. FELDMAN. Well, the impact of it might be tremendous if the experiment was not successful.

Mr. ELLSWORTH. Well, if it is not successful, no particular harm has been done because the whole employment is so small.

Mr. FELDMAN. I wouldn't say that. It might have chain reaction to it even though it is, as you say, small. Because you have over 8,000 people employed at the present time. And that number will increase substantially.

Mr. ELLSWORTH. I notice in this section 10 (a) it refers to the liquidation of NACA, and says that the personal property and personnel et cetera are transferred.

What effect that would have on the employment, I am sure I don't know.

Mr. FELDMAN. It does raise a question as to whether or not those people presently employed under present salaries and who are scientists might not be paid a lower wage than the new scientists coming in and doing the identical work. That possibility could arise.

Mr. ELLSWORTH. I suppose, technically, but practically it wouldn't, I am sure. With this authority, they could adjust it.

The CHAIRMAN. I would like to have you prepare language, as I said, 313, and then additional language which would permit further flexibility without the strictness of 313, where it will be tied up with the Civil Service Commission approving it. In other words, the

language wouldn't necessarily have to apply on an individual basis, but might cover a group in the technical field.

Mr. IRONS. But not going as far as all employees of the Agency.

The CHAIRMAN. No. I am not saying what we will do, but I would like to have it so we can have it before the committee when we are in executive session.

Mr. IRONS. This latter one might cause us some difficulty. We might have to ask for more conversation with your counsel on that latter provision. The word "technical" is pretty broad. And just what you want the Commission to do, I am not sure I fully understand.

The CHAIRMAN. What does the Commission do in these individual cases?

Mr. IRONS. We pass on an individual-case basis.

The CHAIRMAN. I don't like to see you get too far away from the Civil Service Commission, because we know the history of the Commission. And the Commission acts with reasonable speed, as I have observed throughout the years.

In other words, outside of appointment in accordance with civil-service laws, the provisions of this bill, if enacted into law, would free this Agency from the control of the Civil Service Commission, and their obligation would be to make salaries on the basis of equal pay for equal work and so forth.

Mr. ELLSWORTH. The only thing that this section does with reference to the personnel is on the rate of pay. All the other provisions, as I understand it, of civil-service employment are left intact. It is just the pay rate that is involved in this section.

So that the civil service is not really done any particular violence by this section of the bill which exempts the new NASA from the provisions of the Classification Act. We have a lot of people in civil service who are not under the Classification Act. As I said, we have 40 different pay systems. Practically all are under the civil service, but not under the Classification Act.

The CHAIRMAN. Submit your drafts to us. You are not binding yourself by that. You are simply cooperating with the committee. You have had the years of experience in Congress, and you know how jealous committees are of jurisdiction. And I couldn't criticize if they took that position. They may not. I don't know. And I could see where a pretty interesting debate could be raised right on that particular question which might have affect upon the whole bill.

Mr. ELLSWORTH. You have an awfully tough problem here, I believe. One of the big objectives in framing this legislation is to provide as much freedom of action, and freedom of everything, for this Agency, so that it may be able to pursue its rather amazing assignment unhampered. And that is, of course, what this section of the bill is attempting to do.

The CHAIRMAN. You don't have to have freedom for a messenger. You don't have to have freedom for clerks, so far as this agency is concerned. You don't have to have freedom for stenographers. The freedom is where the progress is going to be made in this great field of unfathomable possibilities. And that is going to be among the scientists and technical employees, not disregarding the importance of the others.

But their salaries are fixed by law, just like all others are in every other agency. And I can see, under this, that scientists will benefit, get an increase, and I am for it. I am for it in other agencies. I recognize their importance. I recognize the necessity. On the other hand, if I were a clerk, I don't know whether I would want to see legislation enacted suspending the civil-service pay rate, particularly when I might get a reduced salary.

So, will you draft that language?

Mr. IRONS. Yes; we can, Mr. Chairman.

The CHAIRMAN. Any further questions?

I want to join with my colleagues, Chairman Ellsworth, in thanking you and Mr. Irons. I might also say that you are one of the best appointments, in my opinion, that President Eisenhower has made.

Mr. ELLSWORTH. Thank you very much, Mr. Chairman. That is very fine of you to say and nice for me to hear.

The CHAIRMAN. Thank you.

(The following material was filed with the committee:)

ATTACHMENT 1

PUBLIC LAW 313, 80TH CONGRESS, AUGUST 1, 1947, AS AMENDED

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That (a) the Secretary of Defense is authorized to establish and fix the compensation for not more than one hundred and twenty positions in the Department of Defense and not more than twenty-five positions in the National Security Agency, each such position being established to effectuate those research and development functions, relating to the national defense, military and naval medicine, and any and all other activities of the Department of Defense and the National Security Agency, as the case may be, which require the services of specially qualified scientific or professional personnel

(b) The Chairman of the National Advisory Committee for Aeronautics is authorized to establish and fix the compensation for, in the headquarters and research stations of the National Advisory Committee for Aeronautics, not to exceed thirty positions in the professional and scientific service, each such position being established in order to enable the National Advisory Committee for Aeronautics to secure and retain the services of specially qualified personnel necessary in the discharge of the duty of the Committee to supervise and direct the scientific study of the problems of flight with a view to their practical solution

(c) The rates of compensation for positions established pursuant to the provisions of this act shall not be less than $12,500 per annum nor more than $19,000 per annum and shall be subject to the approval of the Civil Service Commission.

SEC 2 Positions created pursuant to this Act shall be included in the classified civil service of the United States, but appointments to such positions shall be made without competitive examination upon approval of the proposed appointee's qualifications by the Civil Service Commission or such officers or agents as it may designate for this purpose

SEC. 3 The Secretary of Defense [1] and the Chairman of the National Advisory Committee for Aeronautics shall submit to the Congress, not later than December 31 of each year, a report setting forth the number of positions established pursuant to this Act in the National Military Establishment [1] and in the headquarters and research stations of the National Advisory Committee for Aeronautics, respectively,[1] during that calendar year, and the name, rate of compensation, and description of the qualifications of each incumbent, together with a statement of the functions performed by each In any instance where the Secretary [1] or the Chairman, respectively, may consider full public report on these items detrimental to the national security, he is authorized to omit such items from his annual report and, in lieu thereof to present such information in executive sessions of such committees of the Senate and House of Representatives as the presiding officers of those bodies shall designate.

[1] See sec 28 (b) of Act of August 10, 1956, C. 1041, 70A Stat. 631 (An Act to Revise, Codify, and Enact into Law, Title 10 of the United States Code, etc.)

ATTACHMENT 4

THE FEDERAL TOP SALARY NETWORK—BASIC AND HISTORICAL SALARY INFORMATION

United States Civil Service Commission, Bureau of Programs and Standards, Program Planning Division, Pay Systems Section, revised February 1958

I. INTRODUCTION

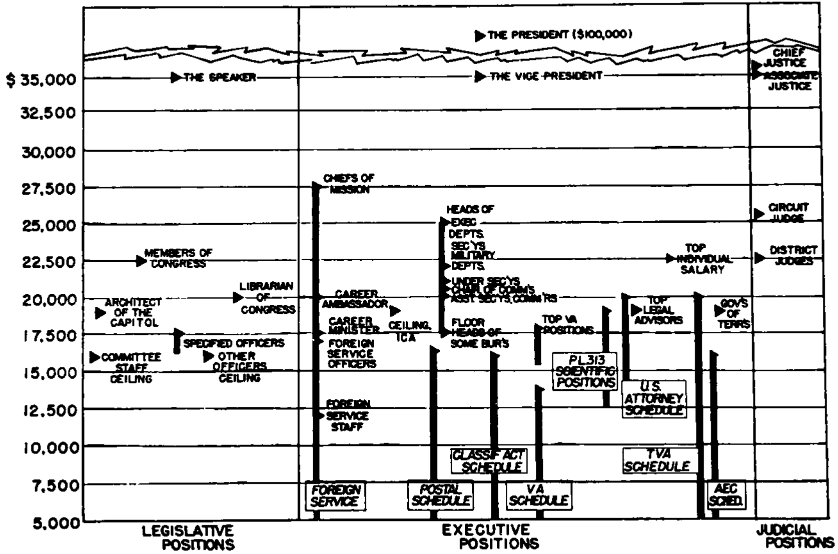
Apart from the President's compensation, a network of annual salary rates from $15,000 to $35,500 forms the top of the salary structure of the Federal Government. The executive, legislative, and judicial branches are all represented.

The rates of this network are either authorized or expressly fixed by statute. Some provisions apply to single positions, others cover classes of positions having substantially equivalent responsibilities; still others combine into a multiple-rate salary schedule. In many instances Congress has fixed a single statutory rate as the only lawful rate. Sometimes, however, it has delegated to an executive agency the authority to fix top salary rates, subject usually to limitations or guidelines, as in the case of the Atomic Energy Commission and the Tennessee Valley Authority. Sometimes, although rarely, it has delegated such power to the President.[1]

In this paper, we (1) show the composition of the Federal top salary network, identifying the various groups or items that should be considered in getting a well-rounded picture, and (2) review the history of top salaries.

[1] Reorganization Act of 1949, as amended and extended, Public Law 109, June 20, 1949, as amended by Public Law 85-286, September 4, 1957; sec. 703 (a), Defense Production Act, Public Law 774, September 8, 1950, as amended by Public Law 632, June 29, 1956.

THE FEDERAL TOP SALARY NETWORK



II. COMPOSITION OF TOP SALARY NETWORK

A considerable number of separate statutes, appropriation riders, and reorganization plans establish or authorize top salary schedules or rates. Within this group of authorizations the Federal Executive Pay Act of 1956 is but 1 statute although a major one, and the ceiling rate of the Classification Act is but 1 item, although a major limitation. Collectively, these schedules and rates constitute a network of top salary relationships within and between the legislative, judicial, and executive branches of the Government.

The composition of this network may be outlined as follows:

Executive branch

	Key rates
The President	$100,000
The Vice President	35,000
Judges, Court of Military Appeals	25,500
The Federal Executive Pay Act:	
Heads of executive departments	25,000
Secretaries of military departments	22,000
Under Secretaries	21,000
Chairmen of most independent boards and commissions	20,500
Assistant Secretaries	20,000
Members, other than chairmen, of most independent boards and commissions	20,000
Governors of Territories and possessions, the top legal adviser in most executive and military departments	19,000
Heads of some bureaus	17,500
Individual top salary provisions, ceiling	22,500
Ceilings of graded schedules:	
Classification Act of 1949, as amended, ceiling	16,000
Postal Field Service Compensation Act of 1955, as amended, ceiling	[1] 16,000
Department of Medicine and Surgery, Veterans' Administration:	
Chief Medical Director	17,800
Deputy Medical Director	16,800
Assistant Medical Directors	15,800
Medical and dental services, ceiling	13,760
Foreign Service, State Department:	
Chiefs of mission:	
Ceiling	27,500
Floor	20,000
Career Ambassador	20,000
Career Minister	17,500
Foreign Service officers, ceiling	17,000
Foreign Service Staff officers and employees, ceiling	11,965
Ceilings of occupational groups:	
Certain professional or scientific research and developmental groups for which Congress has fixed only a minimum rate and a maximum rate:	
Ceiling	19,000
Floor	12,500
United States attorneys and assistant United States attorneys:	
United States attorneys:	
Ceiling	20,000
Floor	12,000
Assistant United States attorneys, ceiling	15,000
Agency ceilings:	
Tennessee Valley Authority, ceiling	20,000
Atomic Energy Commission:	
Scientific and technical personnel, ceiling	19,000
Nonscientific and nontechnical personnel, ceiling	16,000
International Cooperation Administration	19,000

[1] Plus 3 longevity increases of $100 each.

II. COMPOSITION OF TOP SALARY NETWORK—continued

Legislative Branch

	Key rates
The Speaker	$35,000
Members of Congress	22,500
Officers of the Congress:	
Secretary of the Senate, Sergeant at Arms	17,500
Clerk of the House, Sergeant at Arms	17,500
Parliamentarian of the House	20,500
Legislative counsel, Senate	17,500
Legislative counsel, House	16,125
Other officers, ceiling	16,000
Members of committee staffs, ceiling	16,000
Chief of staff, Joint Committee on Internal Revenue Taxation	17,500
Other legislative agencies:	
Librarian of Congress	20,000
Architect of the Capitol	19,000

Judicial Branch

The Federal judiciary:	
Chief Justice of the United States	$35,500
Associate Justices, Supreme Court	35,000
Circuit judges	25,500
District judges	22,500

III. EXECUTIVE BRANCH

A. The President

1789	$25,000
1873	50,000
1909	75,000
1949	100,000

The President's official compensation is $150,000. Of this, $100,000 is salary and $50,000 expense allowance.

Originally established in 1789 at $25,000 a year, the President's salary was raised to $50,000 a year in 1873 and to $75,000 a year in 1909. Effective January 20, 1949, Congress increased it to its present figure of $100,000 (Public Law 2, 81st Cong , January 19, 1949). [1]

In the same law Congress also granted the President an annual expense allowance of $50,000 "to assist in defraying expenses relating to or resulting from the discharge of his official duties." This expense allowance, like those of Members of Congress, the Vice President, and the Speaker, was at first tax-exempt, but the exemption was removed, effective January 20, 1953, by the Revenue Act of 1951. The President is required to account for this allowance for income-tax purposes only.[2]

The President has, of course, the use of the White House and its furnishings, for the care and maintenance of which Congress makes an annual appropriation. Basic law (act of June 23, 1906, as amended August 2, 1946) also authorizes Congress to appropriate and the President to spend not more than $40,000 annually for traveling expenses. Customarily, in current appropriations Congress authorizes travel, official entertainment, and other White House Office expenses in lump sum, without specific limitation on travel

The President is not covered by the Civil Service Retirement Act, A bill, S. 607, passed the Senate on February 4, 1957, which would (*a*) provide each former President of the United States with a monetary allowance of $25,000 per annum for life, (*b*) authorize him to select and employ his own staff, with a limitation on their aggregate compensation, (*c*) authorize suitable office space; and (*d*) grant free postage privileges. No action was taken on the bill by the House of Representatives before the 1st session of the 85th Congress adjourned.

[1] The salary of the President was unaffected by the reductions which took place during the period 1932 to 1935 Art II, sec 1, of the Constitution provides that the compensation of the President "shall neither be increased nor diminished during the period for which he shall have been elected "

[2] Sec 619 of the Revenue Act of 1951, Public Law 183, 82d Cong , approved October 20, 1951, removed the tax exemption from the expense allowances of the President, the Vice President, the Speaker and Members of Congress It struck out the language "no tax liability shall accrue and for which no accounting shall be made by him" and inserted in lieu thereof "no accounting other than for income tax purposes shall be made by him " The expense allowances of the President, the Vice President, and the Speaker are still in effect. Those for Members of Congress were eliminated by sec 4 (b) of Public Law No. 9, 84th Cong.

B. The Vice President

1789	$5,000	1925	$15,000
1853	8,000	1946	20,000
1873	10,000	1949	30,000
1874	8,000	1955	35,000
1909	12,000		

The Vice President's official compensation is $45,000 a year. Of this, $35,000 is salary and $10,000 expense allowances [3]

The salary of the Vice President was first fixed at $5,000 a year in 1789. Successively, it was changed to $8,000 in 1853, to $10,000 in 1873, to $8,000 in 1874 (on repeal of the 1873 provision), to $12,000 in 1909, to $15,000 in 1925, to $20,000 in 1946, to $30,000 in 1949, and to its existing rate of $35,000 by Public Law 9, 84th Congress, effective March 1, 1955.[4]

Public Law 2, 81st Congress, approved January 19, 1949, granted the Vice President an expense allowance of $10,000 a year "to assist in defraying expenses relating to or resulting from the discharge of his official duties, for which no tax liability shall occur or accounting be made by him." The provision freeing this expense allowance from tax liability was repealed, effective January 20, 1953, by the Revenue Act of 1951.

C. The Federal Executive Pay Act of 1956

Coverage.—The Federal Executive Pay Act of 1956, title I of Public Law 854, 84th Congress, July 31, 1956, identified by title and fixed the statutory salary rates of 307 positions in the executive, legislative, and judicial branches of the Government [5] Of these, 284 were in the executive branch, 9 were in the legislative branch;[6] and 14 were in the judicial branch.[7] For most of these positions this was new legislation. However, for the 10 top positions in the Bureau of Medicine and Surgery, the new rates were prescribed by amending existing statutory provisions.

The act also amended the Classification Act of 1949, as amended, and the postal Field Service Compensation Act of 1955 by increasing the top salary rates in their statotory schedules Other amendments in the act increased the minimum and maximum salary rates which certain departments and agencies are authorized by various statutes to establish for specified types or groups of positions.[8]

The laws governing the statutory salary rates for top positions in the Atomic Energy Commission and in the Foreign Service under the Department of State were not amended by the Federal Executive Pay Act.

Major salary groupings

Within the scope of the Federal Executive Pay Act itself, the content of the salary brackets may briefly be described or illustrated as follows:

$25,000—Heads of the 10 executive departments.

$22,500—Deputy Secretary of Defense, Under Secretary of State, Comptroller General of the United States, Director of Defense Mobilization, and the Director of the Bureau of the Budget. This rate is also the maximum limitation on the salary rate of two Presidential aids.

$22,000—Secretaries of the three military departments (Army, Navy, and Air Force).

$21,000—Under Secretaries of 9 executive departments (including the Deputy Postmaster General), President of the Export-Import Bank of Washington, and the heads of 8 single-headed independent establishments (Federal Civil Defense

[3] H. R. 498 and S 2623, introduced in the 1st sess of the 85th Cong, proposed to increase the allowance of the Vice President to $25,000, to provide $20,000 for traveling expenses, and to authorize two administrative assistants with gross salaries not exceeding $18,000 per annum each. Neither of these bills was reported before the first session adjourned

[4] Economy legislation effective in 1932–35 reduced the Vice President's compensation ($15,000) by 15 percent, 10 percent, and 5 percent successively during that period

[5] Prior to Public Law 854, 84th Cong, the salary rates for almost three-fourths of these positions were fixed by the Executive Pay Act of 1949 (Public Law 359, 81st Cong, October 15, 1949, as amended) Pay rates under that act ranged from $22,500 for Cabinet officers to $14,800 for the heads of some major bureaus Some of the 307 positions were formerly paid under the scales of the Classification Act of 1949, others had their rates fixed by various statutes and reorganization plans With few exceptions, the salary rates for top positions in the executive branch are now prescribed by a single statute—the Federal Executive Pay Act of 1956

[6] Architect of the Capitol, Assistant Architect of the Capitol, Comptroller General, Assistant Comptroller General, Librarian of Congress, Chief Assistant Librarian of Congress, Public Printer, Deputy Public Printer, and the Chief of Staff of the Joint Committee on Internal Revenue Taxation

[7] Director and Assistant Director of the Administrative Office of the United States Courts and 12 commissioners of the United States Court of Claims

[8] For example, limitations on certain professional and scientific positions discussed on page 24 of this document and the maximum rates for 15 Presidential aids

Administration, General Services Administration, Housing and Home Finance Agency, Veterans' Administration, Central Intelligence Agency, International Cooperation Administration, United States Information Agency, and the Farm Credit Administration). This is also the rate for the positions of the Director, Federal Bureau of Investigation, and the Commission of Internal Revenue and is the maximum limitation on the salary rate of three Presidential aids. (A rate of $22,000 is provided for the present Director of the Federal Bureau of Investigation.)

$20,500—Chairmen of boards and commissions (20 in number), 3 Deputy Under Secretaries of State, the Comptroller of the Currency, the Director of the Federal Mediation and Conciliation Service, the First Vice President of the Export-Import Bank of Washington, and the deputy and assistant heads of 7 single-headed independent establishments (the Assistant Comptroller General of the United States, the Deputy Administrator of Veterans' Affairs and the Federal Civil Defense Administration; and the Deputy Directors of the Bureau of the Budget, the Central Intelligence Agency, the Office of Defense Mobilization, and the United States Information Agency).

$20,000—Assistant Secretaries of 9 executive departments, Under and Assistant Secretaries of the 3 military departments, members of most independent boards and commissions, heads of 8 single-headed independent establishments (Small Business Administration, St. Lawrence Seaway Development Corporation, Administrative Office of the United States Courts, National Advisory Committee for Aeronautics, National Science Foundation, Selective Service System, Library of Congress, and the Government Printing Office). This is also the rate for the heads of some of the major bureaus and offices under the departments and agencies (the Administrators of Civil Aeronautics, Commodity Stabilization Service, the Rural Electrification Administration, and the Wage and Hour and Public Contracts Divisions, the Commissioners of Community Facilities, Federal Housing Administration, Public Housing Administration, Urban Renewal Administration, and the Director of the Bureau of Prisons. It is also the maximum limitation on the salary rate for seven Presidential aids and is the total compensation rate for the Surgeon General of the Public Health Service, exclusive of his allowance under the Career Compensation Act of 1949, as amended.

$19,000—Governors of Alaska, Hawaii, Guam, the Virgin Islands, and the Canal Zone, the Architect of the Capitol, the Assistant to the Director of the Federal Bureau of Investigation, and the 12 Commissioners of the United States Court of Claims. It is also the rate for the legal adviser, solicitor, or general counsel of most executive or military departments and is the total compensation rate for the Deputy Surgeon General of the Public Health Service exclusive of his allowances under the Career Compensation Act of 1949, as amended. This is also the maximum rate for 21 positions in the International Cooperation Administration and for a limited number of professional and scientific positions in specified departments and agencies.

$18,000—Three Commissioners of the Indian Claims Commission.[9]

$17,800—Chief Medical Director, Department of Medicine and Surgery, Veterans' Administration.

$17,500—Heads of some major bureaus such as the Agricultural Research Service, Bonneville Power Administration, Farmers' Home Administration, Soil Conservation Service, Forest Service, Customs, Federal Supply Service, Immigration and Naturalization, Narcotics, Public Buildings Service, Public Roads, Reclamation, Social Security, and Federal Crop Insurance Corporation. This is also the rate for the Chief of Staff of the Joint Committee on Internal Revenue Taxation, the Deputy Commissioner of the Internal Revenue Service, and the assistant or deputy heads of some single-headed agencies (Assistant Architect of the Capitol, Assistant Director of the Administrative Office of the United States Courts, the Associate Director of the Federal Mediation and Conciliation Service, Chief Assistant Librarian of Congress, Deputy Administrator of the St. Lawrence Seaway Development Corporation, and the Deputy Public Printer). It is also the maximum limitation on the salary rate of three Presidential aids and is the total compensation rate for each of the following employees in addition to their allowances under the Career Compensation Act of 1949, as amended: Director, National Institutes of Health; Chief, Bureau of State Services, and Chief, Bureau of Medical Services, all in the Public Health Service.

[9] The Chief Commissioner receives $500 more as "head" of the Commission under sec. 108 of the act.

$17,000—Three Deputy Administrators of the Small Business Administration and the Treasurer of the United States.

$16,800—Deputy Chief Medical Director, Department of Medicine and Surgery, Veterans' Administration.

$15,800—Assistant Chief Medical Directors, Department of Medicine and Surgery, Veterans' Administration.

History of Cabinet officers' salary rates

	State	Treasury	Attorney General	Postmaster General [1]	Interior	Agriculture	Commerce	Labor	Defense [2]	Health, Education, and Welfare
1789	$3,500	$3,500	$1,500							
1792	--------	--------	--------	$2,000						
1794	--------	--------	--------	2,400						
1797	--------	--------	2,000	--------						
1799	5,000	5,000	3,000	3,000						
1819	6,000	6,000	3,500	4,000						
1827	--------	--------	--------	6,000						
1849	--------	--------	--------	--------	$6,000					
1850	--------	--------	6,000	--------	--------					
1853	8,000	8,000	8,000	8,000	8,000					
1873	10,000	10,000	10,000	10,000	10,000					
1874 [3]	8,000	8,000	8,000	8,000	8,000					
1889	--------	--------	--------	--------	--------	$8,000				
1903	--------	--------	--------	--------	--------	--------	$8,900			
1907	12,000	12,000	12,000	12,000	12,000	12,000	12,000			
1913	--------	--------	--------	--------	--------	--------	--------	$12,000		
1925 [4]	15,000	15,000	15,000	15,000	15,000	15,000	15,000	15,000		
1947	--------	--------	--------	--------	--------	--------	--------	--------	$15,000	
1949	22,500	22,500	22,500	22,500	22,500	22,500	22,500	22,500	22,500	
1953	--------	--------	--------	--------	--------	--------	--------	--------	--------	$22,500
1956	25,000	25,000	25,000	25,000	25,000	25,000	25,000	25,000	25,000	25,000

[1] The Postmaster General became a member of the President's Cabinet in 1829. The Post Office Department became an executive department in 1872.

[2] The Departments of War and Navy, the Secretaries of which were members of the President's Cabinet until 1947, are now military departments under the Department of Defense. As Cabinet officers the salary rate for each Secretary was essentially the same as for Secretary of State

[3] In 1873 Congress increased the pay of top legislative, judicial, and executive officials. (Act of Mar. 3, 1873, 17 Stat. 486) The new rates, however, were repealed the next year, except for the President and Justices of the Supreme Court (Act of Jan. 20, 1874, 18 Stat (pt. 3) 4)

[4] Economy legislation effective in 1932–35 reduced rates 15, 10, and 5 percent successively during that period.

D. Individual top salary provisions

In addition to the positions covered in the Federal Executive Pay Act of 1956, there are 70 other top administrative positions in the executive branch outside the Foreign Service of the State Department for which Congress has fixed a specific individual salary rate or maximum limitation at $15,000 or more.

Thirty-one of these positions have their rates fixed by three statutes which were enacted prior to the Federal Executive Pay Act of 1956. These are—

Three judges of the Court of Military Appeals, Department of Defense whose compensation was fixed at $25,500 by Public Law 9, 84th Congress, effective March 1, 1955.

Ten positions in the Department of Justice which were taken out of the Executive Pay Act of 1949 and given pay increases by Public Law 9, 84th Congress, effective March 1, 1955 These are the Deputy Attorney General ($21,000), the Solicitor General ($20,500), and eight Assistant Attorneys General ($20,000).[10]

Sixteen judges of the Tax Court of the United States ($22,500): The United States Board of Tax Appeals was created by the Revenue Act of 1924 The act of October 21, 1942, changed its name to the Tax Court of the United States.

The salary rate of the 16 judges of the Tax Court of the United States was fixed in 1924 at $7,500, increased in 1939 to $10,000, and in 1946 to $15,000. Public Law 9, 84th Congress, approved March 2, 1955, effective March 1, 1955, raised it to $22,500 per annum The court is in the executive branch but the salary rate of the judges is customarily tied to adjustments in the rates of Federal judges in the judicial branch

[10] Under the Executive Pay Act of 1949, the salary rates for these positions in the Department of Justice were the same as for parallel positions in other executive departments. After they were increased by Public Law 9, numerous bills were introduced to give similar raises to other top executives Such increases were approved in the Federal Executive Pay Act of 1956, July 31, 1956, and made retroactive to the beginning of the first pay period commencing after June 30, 1956

The Agricultural Surplus Disposal Administrator, whose salary is fixed by the Secretary of Agriculture at a rate not in excess of $15,000 under the provisions of Public Law 540, April 28, 1956.

The General Counsel, Department of Health, Education, and Welfare, whose salary is fixed "at the rate now or hereafter provided by law for Assistant Secretaries of executive departments" by Public Law 852, July 31, 1956. The Federal Executive Pay Act, which was enacted almost simultaneously, prescribes a rate of $20,000 per annum for Assistant Secretaries of executive departments.[11]

Thirty-nine other positions (many newly created) are paid at rates fixed by statutes enacted after the Federal Executive Pay Act. Some have their salary rates prescribed by reference to either (1) the rate for a specified group under the Federal Executive Pay Act or (2) a grade of the Classification Act of 1949, as amended. Others have their salary rates specifically stated in the laws:

Assistant Director of the Bureau of the Budget.—Public Law 882, August 1, 1956, established this one additional Assistant Director position and provided that the compensation "shall be the same as is now or may hereafter be provided for the two such positions heretofore authorized by law." (The rate currently prescribed by the Federal Executive Pay Act is $20,000.)

Federal Highway Administrator.—Public Law 966, August 3, 1956, provides compensation "at the rate prescribed by law for Assistant Secretaries of executive departments." (Assistant Secretaries of executive departments receive $20,000 per annum under the Federal Executive Pay Act.)

Assistant Secretary for Fish and Wildlife and Commissioner of Fish and Wildlife.—Public Law 1024, August 8, 1956, provides that the Assistant Secretary "shall be compensated at the same rate as other Assistant Secretaries" and the Commissioner "shall receive compensation at the same rate as that provided for grade GS-18." (Under the Federal Executive Pay Act, the rate for Assistant Secretaries is $20,000 and the rate for grade GS-18 of the Classification Act of 1949, as amended, is $16,000.)

Administrative Assistant Secretary, Department of the Interior.—Public Law 85-167, August 26, 1957, provides that the salary for this position "shall be the same as the Solicitor of the Department of the Interior." (The Solicitor's salary is $19,000, under the Federal Executive Pay Act.)

General Counsel, Department of Defense.—Public Law 85-170, August 28, 1957, provides that this position shall be paid "at the rate prescribed by Reorganization Plan No. 6 approved June 30, 1953 (67 Stat. 638)." Under Reorganization Plan No. 6 of 1953, the salary for the General Counsel for the Department of Defense was fixed at the rate "for Assistant Secretaries of executive departments." In 1956, this provision was superseded by section 106 (b) (9) of the Federal Executive Pay Act which prescribed a salary of $19,000 per annum for each "legal adviser, solicitor, or general counsel of an executive or military department (excluding the Department of Justice)." The effect of Public Law 85-170 was to increase the salary of the General Counsel, Department of Defense, from $19,000 to $20,000, the rate prescribed by the Federal Executive Pay Act for Assistant Secretaries of executive departments.

Chairman, Airways Modernization Board.—Public Law 85-133 prescribes a rate of $20,500 for this position.

Manager of the Fund, International Cooperation Administration.—Public Law 85-141, August 14, 1957, set up a Development Loan Fund and provided that the Manager of the Fund could receive compensation "at a rate not in excess of $19,000 a year."

Twenty-nine positions in the Atomic Energy Commission.—Public Law 85-287, September 4, 1957, raised the statutory rates for 19 top positions in the Atomic Energy Commission which have traditionally had their rates fixed by special statutes. The new rates are: Chairman, $22,500; 4 members, $22,000; General Manager, not to exceed $22,000; General Counsel, not to exceed $19,500; and 12 division directors, not to exceed $19,000. The act also provided statutory salary limitations for 10 additional top-management positions, as follows: Deputy General Manager, not to exceed $20,500; 3 Assistant General Managers or their equivalents, not to exceed $20,000; and 6 other executive-management positions, not to exceed $19,000.

Assistant Attorney General, Department of Justice.—Public Law 85-315, September 9, 1957, established this one additional Assistant Attorney General position and provided compensation "at the rate prescribed by law for other

[11] The Federal Executive Pay Act of 1956 prescribed a salary rate of $19,000 for the chief legal officer of each executive and military department (except Justice). However, the language in Public Law 852 was interpreted as superseding this provision as it related to the General Counsel of the Department of Health, Education, and Welfare.

Assistant Attorneys General." (The salary rate for Assistant Attorneys General is fixed at $20,000 by Public Law 9, March 2, 1955.)

Staff Director, Commission on Civil Rights.—Public Law 85-315, September 9, 1957, provided that a full-time staff director for the Commission on Civil Rights "shall receive compensation at a rate, to be fixed by the President, not in excess of $22,500 a year."

Without changing the salary rates of the positions involved, Congress has in several instances authorized increased rates for the then present incumbents only. The following are current:

	Rate for position	Rate for present incumbent
Position under Federal Executive Pay Act. Director, Federal Bureau of Investigation	$21,000	$22,000
Positions under the Classification Act:		
Comptroller, General Services Administration		[1] 16,000
Administrative Assistant Attorney General (GS-18)	16,000	17,500
Administrator, Southwestern Power Administration (GS-16)	[2] 13,760	[3] 17,500

[1] Present incumbent receives "rate for GS-18."
[2] Maximum
[3] Present incumbent receives same rate as the Administrator, Bonneville Power Administration.

E. Ceilings of graded schedules

The Federal top salary network embraces and controls the ceiling rates of graded schedules established by statute for four major segments of the career service. These schedules and the approximate number of positions which each one covered on June 30, 1957, are as follows.

	Number
The general schedule of the Classification Act of 1949, as amended	[1] 978,750
The schedules for the postal field service under the Postal Field Service Compensation Act of 1955, Public Law 68, 84th Cong., June 10, 1955, as amended	447,000
The Foreign Service schedules of the Foreign Service Act of 1946, as amended	[2] 12,750
The medical, dental, and nursing schedules and rates of the act of Jan. 3, 1946, Public Law 293, 79th Cong., as amended	20,000

[1] Includes positions in the municipal government for the District of Columbia.
[2] Includes positions in the International Cooperation Administration and in the U. S. Information Agency.

Classification Act of 1949, as amended.—The Classification Act of 1949 is a statute of general applicability, not confined to any one department, agency, or occupational group. Its general schedule fixes the rates of pay for professional, scientific, administrative, supervisory, office and other white collar workers in most of the departments and agencies.

The general schedule embraces 18 grades or zones of difficulty and responsibility. Each grade has a statutory range of pay with a scheduled minimum and a scheduled maximum. A longevity step-increase plan permits rates above scheduled maximums in grades GS-1 through GS-15. The longevity step-increase plan does not apply to the three highest grades of the general schedule.

The three highest grades, GS-16, GS-17, and GS-18, were established for the first time in 1949. The number of positions now allowed in these so-called supergrades is 1,226, exclusive of a few statutory exceptions.

The following table shows the characteristics of the top grades of the Classification Act general schedule.

GS grade	Maximum number of positions authorized [1]	Scheduled minimum	Scheduled maximum	Number of rates	Number and amount of steps	Longevity step—increases over maximum
15		$11,610	$12,690	5	4 at $270	3 at $215
16	767	12,900	13,760	5	4 at $215	None
17	329	13,975	14,835	5	4 at $215	None
18	130	16,000		1	Single rate	None.

[1] Exclusive of certain statutory exceptions and other authorizations.

Postal Field Service Compensation Act of 1955, as amended.—For many years pay rates in the postal field service have been fixed by acts of Congress separately from other groups.

Public Law 68 of the 84th Congress, approved June 10, 1955, establishes a set of graded schedules for the postal field service for the first time. There are three such schedules: The postal field service schedule, the rural carrier schedule, and the fourth-class postmaster schedule. The problems which concern salary ceilings involve only the postal field service schedule. This schedule has a scheduled maximum rate of $16,000. This is a single rate, established for level 20 in the schedule. Under the act, however, after 13, 18, and 25 years of postal service, an employee may earn 1, 2, and 3 longevity step increases of $100 each over the scheduled maximum rate of his level

Section 301 (a) of Public Law 68 establishes the postal field service schedule. Section 201 (c) limits the number of positions that may be placed in levels 17, 18, 19, and 20. Section 404 provides a longevity step-increase plan.

The effect of these various provisions of Public Law 68 as amended by Public Law 854, July 31, 1956, on the top grades of the postal field service schedule may be outlined as follows:

PFS Level	Maximum number of positions authorized	Scheduled minimum	Scheduled maximum	Number of rates	Number and amount of steps	Longevity step-increases over maximum
17	40	$11,400	$13,200	7	6 at $300	3 at $100.
18	12	12,800	14,600	7	do	Do
19	4	14,000	15,200	5	4 at $300	Do.
20	15	16,000		1	Single rate	Do.

Foreign Service.—The Foreign Service Act of 1946, as amended, establishes three statutory schedules for officers and employees of the Foreign Service under the State Department. These schedules are also used to compensate certain overseas personnel of other agencies, such as the United States Information Agency and the International Cooperation Administration. (Sec. 527 (c), Mutual Security Act of 1954, as amended, Public Law 665, 83d Cong., August 26, 1954; Executive Order 10610, May 9, 1955.)

The three schedules are for·

Chiefs of Mission (sec. 411): Four classes as follows Class 1, $27,500; class 2, $25,000; class 3, $22,500 and class 4, $20,000.

Foreign Service officers and Foreign Service reserve officers (sec. 412): 10 classes with associated salary ranges or rates. The minimum of the schedule is $4,300. The top rates are: The single rate of $20,000 for career ambassador; the single rate of $17,500 for career minister, and the $17,000 maximum rate for Foreign Service officer class 1 The schedule for Foreign Service officers applies to Foreign Service reserve officers.

Foreign Service staff officers and employees (sec. 415) 22 classes, beginning with a minimum of $1,455 in class 22 and running to the maximum rate of class 1 which is $11,965.

A $17,500 salary ceiling rate was authorized for ambassadors as early as 1855 (act of March 1, 1885, 10 Stat 619, sec. 1). It was raised to $25,000, effective November 13, 1946, by the Foreign Service Act of 1946, Public Law 724, 79th Congress, August 13, 1946 The present $27,500 rate was established by Public Law 828, July 28, 1956, which amended the Foreign Service Act of 1946.

The salaries at the top structure of the Department of State are as follows: Secretary of State, $25,000; Under Secretary of State, $22,500; 3 Deputy Under Secretaries, $20,500; 10 Assistant Secretaries, $20,000. The rates for these executives are fixed by the Federal Executive Pay Act of 1956.

The history of the top rates in the Foreign Service schedules is shown in the following table.

Maximum rates, foreign service schedules, 1946–56

	Approximate number of employees [1] October 1957	Public Law 724, 79th Cong., August 13, 1946 effective November 13, 1946	Public Law 160, 81st Cong., July 6, 1949 effective July 11, 1948	Public Law 201, 82d Cong., October 24, 1951 effective July 8, 1951	Public Law 94, 84th Cong., June 28, 1955 effective March 13, 1955	Public Law 250 84th Cong. effective August 5, 1955	Public Law 828 84th Cong. effective July 29, 1956
Chiefs of mission (79)							
Class 1	14	$25,000	(2)	(2)	(2)	(2)	$27,500
Class 2	27	20,000	(2)	(2)	(2)	(2)	25,000
Class 3	22	17,500	(2)	(2)	(2)	(2)	22,500
Class 4	16	15,000	(2)	(2)	(2)	(2)	20,000
Foreign Service officers (including FSRO):							
Career ambassador	2	----------	----------	----------	----------	$15,000	20,000
Career minister	14	13,500	$13,500	$14,300	$14,800	(2)	17,500
Class 1	[3] 5	13,500	13,500	14,300	14,800	(2)	17,000
Foreign Service Staff officers and employees: Class 1	[4] 113	10,000	10,300	11,130	11,965	(2)	(2)

[1] Includes positions in International Cooperation Administration and in the U S Information Agency.
[2] No change.
[3] Maximum number out of total of 212 in class 1.
[4] Maximum number out of total of 350 in class 1.

Veterans' Administration, Department of Medicine and Surgery.—The Department of Medicine and Surgery in the Veterans' Administration was established by Public Law 293, 79th Congress, January 3, 1946. That act, as amended and supplemented, fixes the pay for the Chief Medical Director and 35 other top positions in the Department by specifying the salaries for designated positions. It also establishes three graded schedules—the Medical, Dental, and Nursing Services. The most recent amendment to Public Law 293 was contained in the Federal Executive Pay Act of 1956.

As of June 30, 1957, these schedules covered almost 20,000 full-time positions: 4,619 physicians, 769 dentists, and 14,379 nurses.

The statutory rates for 10 of the top positions were increased, along with those for many other Federal executives, by the provisions of the Federal Executive Pay Act of 1956. These are the Chief Medical Director ($17,800), the Deputy Chief Medical Director ($16,800), and not to exceed 8 Assistant Medical Directors ($15,800). Under the Federal Executive Pay Act the salary of the Administrator of Veterans' Affairs is $21,000 and that of the Deputy Administrator is $20,500.[12]

The history of the establishment of maximum rates for the 36 positions and the 3 schedules concerned is shown in the following table:

[12] During the 1st sess of the 85th Cong. a bill, H R. 6719, was introduced to provide, among other things, salary increases for certain professional employees of the Department of Medicine and Surgery. The bill, as amended and reported by the House Committee on Veterans' Affairs (Rept. No. 796, pts 1 and 2), proposed a rate of $19,500 for the Chief Medical Director, $18,500 for the Deputy Chief Medical Director, $17,500 for each Assistant Chief Medical Director, and $16,000 for directors of service or chiefs of division. Increases were also proposed for the Director, Nursing Service, the chief dietitian and the chief pharmacist, as well as for employees paid under the schedules for the Medical, Dental, and Nursing Services. The House did not take action on H R 6719 before the 1st session of Congress adjourned.

Maximum rates, positions and schedules, Veterans Administration, Department of Medicine and Surgery, 1946–56

	Public Law 293, 79th Cong, January 3, 1946	Public Law 349, 81st Cong, October 12, 1949, effective December 1, 1949	Public Law 201, 82d Cong, October 24, 1951, effective July 8, 1951	Public Law 94, 84th Cong, June 28, 1955, effective March 13, 1955	Public Law 854, 84th Cong, July 31, 1956, effective July 1, 1956
Chief Medical Director (1)	$12,000	$16,000	$16,800	(1) (2)	$17,800
Deputy Chief Medical Director (1)	11,500	15,000	15,800	(1) (2)	16,800
Assistant Chief Medical Directors (note 8)	11,000	14,000	14,800	(1) (2)	15,800
Directors of Service or Chief of Division (note 20)		12,500	13,300	$14,300	(2)

[1] Changes from 1951 are based on Public Law 94, 84th Cong

[2] All 1956 rates were fixed by Public Law 854, 84th Cong, except those in the Foreign Service which were established by Public Law 828, 84th Cong

[3] Maximum limitation on aggregate of highest scheduled basic rate plus 3 longevity increases of $100 each after 13, 18, and 25 years of service, respectively

[4] Class of Career Ambassador established by Public Law 250, 84th Cong, Aug 5, 1955

[5] Class of Career Minister established by Public Law 724, 79th Cong, Aug 13, 1946

[6] Ceiling for "senior clerk", a $5,600 ceiling for "administrative officer, class 1" was established by law May 3, 1945, this ceiling was revised to $7,102 20 by statute in July 1945

[7] Maximum limitation on aggregate of scheduled basic rate plus not to exceed 25 percent additional for specialist rating

F. Ceilings of occupational groups

Professional or scientific research and development positions in specified agencies.

In several enactments since 1947, Congress has authorized a specified salary range (in the Department of Agriculture and the Airways Modernization Board, a maximum) for a limited number of professional or scientific research and development positions in the Department of Defense, the National Security Agency, the National Advisory Committee for Aeronautics, the Public Health Service, the Department of Agriculture and the Airways Modernization Board. The original salary range of $10,000–$15,000 was increased to $12,500–$19,000 by the Federal Executive Pay Act of 1956, effective at the beginning of the first pay period commencing after June 30, 1956 [13] Simultaneously, the maximum for such positions in the Department of Agriculture was raised from $15,000 to $19,000. Except in the Department of Agriculture, the Civil Service Commission must approve in advance the salary rate to be established for each position and any subsequent changes within the $12,500–$19,000 range

The number of such positions now authorized is as follows:

Agency	Number of positions	Authority
Department of Defense	120	Public Law 1028, 84th Cong, Aug 10, 1956, as amended by Public Law 854, 84th Cong, July 31, 1956.[1]
	15	Public Law 85-322, Feb 11, 1958
National Security Agency	25	Public Law 313, 80th Cong, Aug 1, 1947, as amended by Public Law 758, 80th Cong, June 24, 1948, Public Law 167, 81st Cong, July 13, 1949 and Public Law 854, 84th Cong, July 31, 1956
National Advisory Committee for Aeronautics	30	
Public Health Service	60	Public Law 410, 78th Cong, July 1, 1944, as amended by Public Law 692, 81st Cong, Aug 15, 1950, Public Law 195, 84th Cong, Aug 1, 1955, and Public Law 854, July 31, 1956
Department of Agriculture	5	Act of May 29, 1884, as amended by Public Law 496, 80th Cong, Apr 24, 1948, and Public Law 854, July 31, 1956
Airways Modernization Board	5	Public Law 85-133, August 14, 1957.

[1] Prior to the recodification of title 10 of the U S Code in Public Law 1028, 84th Cong, this authority was contained in Public Law 313, 80th Cong, as amended

United States attorneys and assistant United States attorneys—As a result of certain mandatory requirements of the act of July 3, 1930, the scope of the pay schedules of the Classification Act was extended to include U S attorneys and assistant U S attorneys Between 1930 and 1953 rates for these positions were fixed administratively by the Department of Justice pursuant to Classification Act schedules, except that a special authority permitted a $10,000 rate for United States attorneys at New York City, Chicago, and Washington. During that period the ceiling of the Classification Act was increased from $9,000 to $14,800.

Section 202 of the Department of Justice Appropriation Act, 1954 (Public Law 195, 83d Cong, August 5, 1953) took United States attorneys and Assistant United States Attorneys out of the Classification Act schedules It established for the Attorney positions a range from $10,000 minimum to $15,000 maximum and for the assistant positions a range from $6,000 to $12,000

Public Law 471, 83d Congress, July 2, 1954, eliminated both minimum figures.

Effective March 1, 1955, Public Law 9, 84th Congress, March 2, 1955, raised these limitations United States attorneys may be paid not less than $12,000 nor more than $20,000, assistant United States attorneys not more than $15,000 (28 U S C 508)

[13] The maximum of the range for positions in the Public Health Service was raised to $20,000 by Public Law 635, June 29, 1956, but was later changed by Public Law 854, July 31, 1956, to correspond with the $12,500–$19,000 range for similar positions in other agencies

The chronology is shown in the following summary:

UNITED STATES ATTORNEYS

	Minimum	Maximum	
1923	$3,000	[1] $7,500	Act of Mar 4, 1923, 42 Stat. 1560.
1930		[1] 9,000	Classification Act pay schedules.
1945		[1] 9,800	
1946		10,000	
1948		10,330	
1949		11,000	
1951		11,800	
1953	10,000	15,000	Public Law 195, 83d Cong., Aug. 5, 1953.
1954		15,000	Public Law 471, 83d Cong, July 2, 1954.
1955	12,000	20,000	Public Law 9, 84th Cong., Mar. 2, 1955.

ASSISTANT UNITED STATES ATTORNEYS

1953	$6,000	$12,000	Public Law 195, 83d Cong.
1954		12,000	Public Law 471, 83d Cong
1955		15,000	Public Law 9, 84th Cong.

[1] United States attorneys for New York City, Chicago, and Washington, D. C., were paid $10,000 per annum under special authority.

G. Agency ceilings

Atomic Energy Commission.—The salaries of the members and certain other top executives in the Atomic Energy Commission are prescribed by statute or are authorized to be fixed up to a specified maximum above the Classification Act ceiling. The salary rates for other positions are not necessarily subject to the Classification Act or any other statutory schedule but are subject to certain maximum limitations prescribed in section 161d of the Atomic Energy Act of 1954, as amended.

Section 161d authorizes the Commission to "appoint and fix the compensation of such officers and employees as may be necessary to carry out the functions of the Commission. Such officers and employees shall be appointed in accordance with civil-service laws and their compensation fixed in accordance with the Classification Act of 1949, as amended, except that to the extent the Commission deems such action necessary to the discharge of its responsibilities, personnel may be employed and their compensation fixed without regard to such laws: *Provided, however*, That no officer or employee (except such scientific and technical personnel up to a limit of $19,000) whose position would be subject to the Classification Act of 1949, as amended, if such Act were applicable to such position, shall be paid a salary at a rate in excess of the rate payable under such Act for positions of equivalent difficulty or responsibility."

This provision (except for the limitation on salaries of scientific and technical personnel) appeared in Atomic Energy Commission appropriation items for many years before it was included as permanent legislation in the Atomic Energy Act of 1954. The $19,000 limitation on the salary rates for scientific and technical personnel was added by an amendment in Public Law 85-287, September 4, 1957.

Prior to the amendment in Public Law 85-287, section 161d of the Atomic Energy Act of 1954 gave the Atomic Energy Commission complete authority to fix rates for its scientific and technical personnel. The Commission had used this authority to provide top salaries for such employees as the Deputy and Assistant General Managers and the managers of certain field operations offices. When legislation was being considered to increase the salaries of top officials in the Atomic Energy Commission, the Joint Committee on Atomic Energy noted that the salary rates for these positions were to be specifically covered by amendments to sections of the Atomic Energy Act of 1954 other than section 161d. Therefore, they concluded that a limitation could properly be put on the maximum salaries payable to scientific and technical personnel under that section. The committee's report on the proposed legislation stated, "Although the committee recognizes that it is important to the successful operation of the Commission to be able to obtain first-rate scientific and technical persons, the committee believes that such persons should not receive salaries in excess of that of the program division directors, whose salary is to be a maximum of $19,000." [14]

[14] S. Rept. No. 790 on S. 2672 and H. Rept. No. 977 on H. R. 8994.

Public Law 85–287 did not affect the statutory limitation on the salary rates for personnel other than officers paid at statutory rates and scientific and technical personnel. No officer or employee whose position is of the kind normally covered by the Classification Act may be paid more than he would receive under the Classification Act in a position of equivalent difficulty or responsibility.

Farm Credit Administration.—In 1933 the Farm Credit Act established a ceiling of $10,000 on the compensation of any "director, officer, or employee of the central bank for cooperatives, or of any production credit corporation, production credit association, or bank for cooperatives."

In subsequent years, in connection with general pay increase measures, this ceiling has been lifted as follows:

1933: $10,000 (sec. 66, Act of June 16, 1933, 12 U. S. C., 1138f).
1949: $13,000 (sec. 1201, Classification Act of 1949).
1951: $13,800 (sec. 3, Public Law 201, 82d Cong., approved October 24, 1951).
1955: $14,620 (sec. 5, Public Law 94, 84th Cong., June 28, 1955).

International Cooperation Administration.—Section 527 (b) of the Mutual Security Act of 1954, Public Law 665, 83d Cong., August 26, 1954, limits to a maximum of 60 the number of officers or employees employed in the United States on authorized mutual security programs who may be paid without regard to the Classification Act.

Of these 60, not more than 35 may be paid higher than the scheduled maximum of GS–15 ($12,690). Of these 35, not more than 15 may be paid in excess of the highest rate for the general schedule (GS–18, $16,000) but not in excess of $19,000.

This, for the Foreign Operations Administration was a modified continuation of authority given the former Economic Cooperation Administration in 1948. The International Cooperation Administration succeeded Foreign Operations Administration under the provisions of Executive Order 10610, May 9, 1955.

The International Cooperation Administration is also authorized to administratively fix the salary rates for six additional positions. This authority was originally granted to the Foreign Operations Administration by Reorganization Plan No. 7 of 1953 and was transferred to the International Cooperation Administration by Executive Order 10610. The ceiling rate for these positions, as increased by the Federal Executive Pay Act of 1956, is $19,000.

Tennessee Valley Authority.—The Tennessee Valley Authority is not subject to the Classification Act or any other statutory schedule. The salary rate of members (other than the Chairman) of the Tennessee Valley Authority Board is fixed at $20,000 by the Federal Executive Pay Act of 1956. The rate for the Chairman is $20,500.

Section 3 of the Tennessee Valley Authority's organic act of May 18, 1933, established the Board members' salary rate as the agency ceiling. The law provides:

"The Board shall without regard to the provisions of Civil Service laws applicable to officers and employees of the United States, appoint such Managers, Assistant Managers, officers, employees, attorneys, and agents as are necessary for the transaction of its business, fix their compensation, define their duties, * * *. No regular officer or employee of the Corporation shall receive a salary in excess of that received by the members of the Board."

IV. LEGISLATIVE BRANCH

A. The Speaker of the House

Originally	[1] $12	1874	$8,000
1816	3,000	1907	12,000
1817	[1] 16	1925	15,000
1856	6,000	1946	20,000
1866	8,000	1949	30,000
1873	10,000	1955	35,000

[1] A day.

The Speaker's official compensation is $45,000 a year. Of this, $35,000 is salary and $10,000 expense allowance.

The pay of the Speaker of the House, originally $12 a day, was changed to an annual salary of $3,000 a year in 1816 and reverted to a daily rate, $16, the next year. It was raised to an annual salary of $6,000 in 1856, to $8,000 in 1866, to $10,000 in 1873, reverted to $8,000 in 1874 on repeal of the 1873 law, was raised to $12,000 in 1907, to $15,000 in 1925, to $20,000 in 1946, to $30,000 by Public

Law 2, 81st Congress, in 1949, and to $35,000 by Public Law 9, 84th Congress, in 1955.[15]

Public Law 2, 81st Congress, also provided the Speaker with an expense allowance of $10,000 a year. At first tax free, this allowance was made subject to income taxation in 1953.

B. Members of Congress

Prior to 1856	(1)	1933–34	$8,500
1856	(2)	1934	9,000
1866	$5,000	1934–35	9,500
1873	7,500	1935	10,000
1874 [3]	5,000	1946	[5] 15,000
1907	7,500	1949	[5] 15,000
1925	10,000	1955	22,500
1932–33 [4]	9,000		

[1] $6, $7, or $8 a day during attendance (except $1,500 a year in 1816–17).
[2] $6,000 for each Congress ($3,000 a year)
[3] In 1873 Congress increased the pay of top legislative, judicial, and executive officials (act of Mar 3, 1873, 17 Stat 486) The new rates, however, were repealed the next year, except for the President and Justices of the Supreme Court (act of Jan 20, 1874, 18 Stat (pt 3) 4)
[4] Economy legislation in the period 1932–35 reduced the salary rates of Members of Congress as follows: Public 212, 72d Cong., June 30, 1932, 10 percent from July 1, 1932, to Apr 1, 1933, Public 2, 73d Cong., Mar 20, 1933, as amended 15 percent from Apr 1, 1933, to Jan 31, 1934, 10 percent from Feb 1, 1934, to June 30, 1934, and 5 percent from July 1, 1934, to Mar 31, 1935
[5] Total compensation Includes a $2,500 expense allowance, which was tax free until 1953 when it was made taxable under the provisions of the Revenue Act of Oct 20, 1951 This allowance was discontinued, effective Mar 1, 1955, by Public Law 9, 84th Cong, approved Mar 2, 1955 For income-tax purposes, Members of Congress may deduct up to $3,000 a year for living expenses (26 U S C. Supp. IV 162 (a) (3)).

C Top officers of the Congress

Several laws and resolutions in the 84th Congress fixed new individual gross salary rates for some of the top officers of the Congress These current salaries are as follows:

Position	*Gross rate*
Senate:	
Secretary of the Senate	$17,500
Sergeant at Arms	17,500
Secretary for the majority	15,500
Secretary for the minority	15,500
Chief Clerk	15,500
Parliamentarian	15,500
Legislative Counsel	17,500
Senior counsels (3)	15,500
House:	
Clerk of the House	17,500
Sergeant at Arms	17,500
Parliamentarian	20,500
Assistant Parliamentarian No. 1	16,500
Doorkeeper	16,500
Legislative counsel	16,125
House minority clerk	15,000
House minority sergeant at arms	15,000
Postmaster	14,500
House minority doorkeeper	12,500
House minority postmaster	11,000
Joint:	
Chief of staff of the Joint Committee on Internal Revenue Taxation	17,500

D Committee staffs

The salary rates or ceilings for members of committee staffs and certain other employees under the Congress are usually expressed in laws or resolutions as "basic" rates. Their total or "gross" salaries are determined by adding specified percentages and dollar amounts to the "basic" rate.

The Legislative Reorganization Act of 1946, Public Law 601, 79th Congress, August 2, 1946, section 202 (e), fixed a "basic" salary rate of $8,000 as the ceiling for professional staff members of standing committees of the House and the Senate. This rate was the pre-1945 minimum rate of the highest scheduled grade of the Classification Act, CAF–15.

[15] Economy legislation effective in 1932–35 reduced the Speaker's compensation 15, 10, and 5 percent, successively, during that period.

Public Law 201, 82d Congress, October 24, 1951, section 2 (b), limited the "gross" salary of committee and most other legislative employees to $11,646 unless otherwise expressly authorized by law.

Public Law 94, 84th Congress, June 28, 1955, section 4 (b), changed the $11,646 ceiling to "the highest per annum rate of compensation paid under authority of the Classification Act of 1949, as amended," then $14,800. Since a "basic" rate of $8,000 computed to a "gross" rate of less than $14,800 ($14,638), the "basic" salary ceiling of the Legislative Reorganization Act of 1946 was raised from $8,000 to $8,820 in order to have it correspond to the "gross" salary ceiling of $14,800 permitted by Public Law 94.[16] (A "basic" salary of $8,820 computes to a "gross" rate of $14,836.)

In the closing days of the 2d session, the 84th Congress raised the highest rate of the Classification Act to $16,000, thereby increasing the "gross" salary ceiling for these legislative employees but not affecting the "basic" rate of $8,820. Thus the maximum "gross" salary which an employee can actually be paid is now $14,836 [17]

E. Other legislative agencies

The salary rates of the heads and assistant heads of several legislative agencies are fixed by the Federal Executive Pay Act of 1956. These are:

General Accounting Office.	
Comptroller General	22, 500
Assistant Comptroller General	20, 500
Government Printing Office.	
Public Printer	20, 000
Deputy Public Printer	17, 500
Library of Congress	
Librarian of Congress	20, 000
Chief Assistant Librarian of Congress	17, 500
Office of the Architect of the Capitol.	
Architect of the Capitol	19, 000
Assistant Architect of the Capitol	17, 500

V. JUDICIAL BRANCH

A. Federal judges

Year	District judges	Circuit or courts of appeals judges	Associate Justices of Supreme Court	Chief Justice of the United States
1789			$3, 500	$4, 000
1819			4, 500	5, 000
1855			6, 000	6, 500
1871			8, 000	8, 500
1873			10, 000	10, 500
1891	[1] $5, 000	$6, 000	(2)	(2)
1903	6, 000	7, 000	12, 500	13, 000
1911	(2)	(2)	14, 500	15, 000
1919	7, 500	8, 500	(2)	(2)
1926 [3]	10, 000	12, 500	20, 000	20, 500
1946	15, 000	17, 500	25, 000	25, 500
1955	22, 500	25, 500	35, 000	35, 500

[1] Until 1891 salaries of district judges varied in the several districts In that year a uniform salary of $5,000 was fixed (26 Stat 783)

[2] No changes

[3] The salaries of judges of the Supreme Court of the United States and other Federal courts were unaffected by the reductions which took place in 1932 to 1935 Art III, sec 1, of the Constitution provides that Federal judges' compensation "shall not be diminished during their continuance in office." Judges who took office on or before June 6, 1932, were not subject to income-tax laws until 1939. Those who took office after that date were subject to the Revenue Act of 1932 and subsequent tax laws (Public Salary Act of 1939, Public Law 32, 76th Cong , 1st sess)

[16] Sec. 12 of Public Law 242, 84th Cong , August 5, 1955 This same act provided that only 1 employee of each standing or select committee of the Senate and of each joint committee of the 2 Houses, the expenses of which are paid from the contingent fund of the Senate, may be paid a basic salary as high as $8,820

[17] Public Law 242, August 5, 1955, limits the gross salary for employees of Senate committees to $14,800.

B. Administative Officer of United States Courts

The salary rates of the Director and the Assistant Director of the Administrative Office of the United States Courts under the Federal Executive Pay Act of 1956 are $20,000 and $17,500, respectively.

C. Commissioners of the United States Court of Claims

The pay of the Commissioners of the United States Court of Claims is fixed under the Federal Executive Pay Act of 1956. Prior to that act their rates were established by the Executive Pay Act of 1949 and increased by Public Law 201, October 24, 1951.

1949	$14,000
1951	14,800
1956	19,000

There are now 12 such Commissioners.

The salary rates of the judges of the court have been as follows:

1946	$17,500
1955	25,500

D. Referees in bankruptcy

The pay of full-time and part-time referees in bankruptcy is limited by maximum rates established by section 40a of the Bankruptcy Act of July 1, 1898, as amended (11 U. S C. 68 (a)).

The Referees' Salary Act of 1946 raised the limit to $10,000 for full-time referees. In 1952 this was increased to $12,500 in relation to the $15,000 salary of Federal district judges

After the salary rate for Federal district judges was raised to $22,500 by Public Law 9, effective March 1, 1955, Congress passed legislation raising the maximum rate for full-time referees to $15,000 and that for part-time referees to $7,500 (Public Law 518, May 10, 1956). The precise salary of a given referee is determined by the Judicial Conference of the United States after advising with the judicial councils, district court judges, and the Director of the Administrative Office of the United States Courts. The law requires that in fixing the amount of salary to be paid a referee, consideration shall be given to the average number and types of, and the average amount of gross assets realized from, cases closed and pending in the territory which the referee is to serve, during the last preceding period of 10 years, and to such other factors as may be material. Disbursement shall be made monthly by or pursuant to order of the Director.

There are now 88 full-time and 75 part-time referee positions.

Customarily, referees' clerks and stenographers are included when pay increases are enacted for the Federal service generally, however, the referees themselves are not usually covered.

The CHAIRMAN. The next witness is Dr. B. Litman (doctor of philosophy), project head, inertial equipment, American Bosch Arma Corp.

STATEMENT OF B. LITMAN, PH. D. PROJECT HEAD, INERTIAL EQUIPMENT, AMERICAN BOSCH ARMA CORP.

Dr. LITMAN. I have a rather short prepared statement, Mr. Chairman.

What I would like to talk about today is the area of guidance and control.

Any problem of navigation essentially has to answer two questions at all times:

1. Where am I?
2. Where am I going?

The possibility of answering the first question hinges on the existence of a fixed reference system, such as landmarks over solid earth or geographical coordinates at sea.

As to the second question (again taking navigation upon the earth as an example), it is necessary to define a reference direction, such as

true north, and compare this northerly direction with the direction of velocity of the vehicle.

Inertial guidance as applied to vehicles traveling the earth utilizes equipment which first of all monitors fixed directions with respect to which we measure our motion.

This is accomplished by what is called an inertial platform, i e., a physical structure continuously kept in a fixed angular direction in space by reference to a set of gyroscopes mounted on the platform. Gyroscopes have the property of maintaining a fixed direction in space with great accuracy when they are properly designed.

In order to determine one's position, the vehicle's acceleration (i. e., change of velocity with time) is sensed. A set of accelerometers is mounted on the inertial platform; these provide information about the vehicle acceleration as seen in the principal directions of our reference system. These data are continuously fed to a computer which calculates vehicle velocity and vehicle position as a function of time.

The principles just mentioned represent a simplified picture of reality and in actual equipment the situation is more involved. Suffice it to say that an inertial navigation system, by its very nature, is self-contained, since no exchange of energy of any sort (like radio waves, optical sighting, et cetera) is required with the outside environment.

Because of this feature, its operation cannot be detected by an external observer. It cannot be jammed, disturbed by weather conditions, or its accuracy impaired by countermeasures.

All that is required to navigate and/or guide a vehicle in a precise and reliable way is to have high precision components, together with a supporting technology which is presently available and common for all navigation and guidance systems.

During the past years, considerable improvement in performance of inertial equipment has been achieved. As a result, it has become possible to construct and successfully test an array of inertially guided vehicles of all sorts, ranging from surface ships to inertially guided long-range missiles. The industry currently is turning out equipment of smaller size and weight, greater reliability and flexibility, and having a broader applicability.

Application of inertial principles to space flight raises specific problems of its own, partly because the environment of operation is not known with sufficient certainty, but mainly because of three fundamental conditions prevailing in outer space not encountered in applications of surface navigation.

These new elements are:

1. The length of duration of navigation, which causes the unavoidable imperfections of components to result in velocity and position errors. These errors accumulate at a high rate, as the duration of flight increases.

2. The trajectory to be followed by the vehicle in interplanetary flight (from the earth to the moon or again from the earth to keep a rendezvous with a manmade satellite) has to be followed very precisely and should be clearly defined and expressed in appropriate space coordinates. Not only should the trajectory be followed precisely for a successful mission, but the timing along said trajectory should be held within very close tolerances.

3. Since the powered portion of any long-distance space flight is but a small portion of the overall trajectory covered, the unpowered por-

tion of flight is featured by a so-called free fall behavior (although there is no "fall" in the usual sense of the word). This results in an apparent gravity-free environment in which the accelerometers continuously sense zero acceleration.

On account of item 3, it would seem that inertial guidance applied to space vehicles is of no value except during takeoff and landing, when powered thrust is applied. Actually, as a result of extensive studies conducted in this field, it appears that an appropriate instrumentation composed of basic inertial components should overcome the difficulty just mentioned.

The method is essentially based on the measurement of acceleration differences prevailing at any instant between any two opposite ends of the space occupied by a vehicle, while the center of the vehicle itself experiences no apparent acceleration. Thus as we approach one of the planets, there will be a rapidly converging gravity field (converging toward the center of the planet) and we will see differences in the acceleration force sensed by the two accelerometers.

Knowing the distance between accelerometers thus provided, the output difference of these accelerometers offers the information desired. Having separated the gravity component from the true acceleration components, the techniques worked out for inertial navigation upon the surface of the earth can be extended without major modifications to the problems of space travel, especially in the vicinity of either the earth or a planet.

The components and techniques pertaining to this type of navigation are within our reach, and any company already engaged in inertial instrumentation should be able and qualified to undertake successfully the building of inertial instruments for space navigation.

This result is but one of the few important breakthroughs that present-day engineering efforts have managed to accomplish. Other navigation schemes will utilize celestial observations or other methods in combination with inertial equipment

In all cases, we find that inertial help is required if only for the purpose of introducing small correcting thrusts for trajectory corrections and monitoring the amount of the correction which has been introduced.

The continued study of similar techniques and development of better hardware is in progress today both as part of continuing efforts in land navigation and forthcoming applications to space travel. There is every indication that the rate of progress in the past will be maintained in the future so that we may look forward to continued improvement and innovations in the application of inertial guidance to space travel.

These improvements will also be of direct use for many of the more conventional earthbound methods of travel.

This little model is perhaps a little bit complex to go through all the details. I might say it has proven of use even for our own engineering people in designing systems.

It shows a structure which will enable the central package to stay in a fixed direction in space in spite of the maneuvering of the satellite or other space vehicle. We indicate on it the gyros which will hold it rigidly in space; the accelerometers which are used to sense the acceleration, and hence, determine the actual movement of the platform.

25973—58——90

This does not show actual working details which in our present work is, of course, classified. But this does give a fair idea of what such platform will look like.

I think we can say the general order of magnitude of the size is not out of line with what we would actually have.

If there are any questions, I would be happy to discuss them.

Mr. HAYS. I have a question, Doctor Litman, first in semantics. I want to understand the word "inertial."

Dr. LITMAN. Well, we utilize this word because any inert mass—anything we have in this world—has mass. Any such body when you accelerate it, when you change its speed, experiences a force. For example, when you are driving a car, you know that when you apply the brakes there is a force on your body. Any body will experience such a force

We can say that the force is proportional to the acceleration, or proportional to the rate at which we are changing speed. This is the basic idea we utilize. We measure such a force in the device we call an acclerometer.

This tells us how fast our speed is changing. From this we can proceed to do some computations and decide how fast we are going and how far we have traveled.

Mr HAYS Then inertia has reference to condition of an object as to whether it is in motion?

Dr LITMAN. Yes; I would say you could describe it that way.

It is just the fact that any object requires a force to bring it up to speed. Any object has inertia, and inertia is a property which says that to speed it up you have to push on it or apply force.

Mr. HAYS. Would you call this a vehicle?

Dr. LITMAN. We refer to this as an inertial platform. It is actually our sensing unit which determines how the satellite or space vehicle is moving.

Mr. HAYS And that is not something designed to go into space itself?

Dr. LITMAN. Yes; this would be placed within the space vehicle. It would travel with it as a self-contained navigation system in the space vehicle. It would continuously put out data saying how fast or how far we have gone.

Mr McDONOUGH. This is a guidance system?

Dr. LITMAN. This would be the guidance system; yes.

Mr. McDONOUGH. Stabilizer?

Dr. LITMAN. Yes; it is in a sense a stabilizer.

This data that it puts out would be used then to control space vehicles, to steer it in the right direction, and to carry it to the right point in space.

Mr. McDONOUGH Would the gentleman yield?

Mr. HAYS. Yes, I do.

Mr. McDONOUGH. In what do we use this type of stabilizer at the present time; in a surface vehicle?

Dr. LITMAN There have been applications of inertial guidance equipment to shipboard use; a number of different aircraft applications; and many of the modern long-distance missiles, including the ballistics missile

I do not think I can refer to specific applications. Most of the present-day applications have been military so far.

Mr. McDonough. In other words, there is no surface vehicle that rolls on wheels that needs this kind of a system?

Dr. Litman. In the case of a vehicle that goes on wheels, we have a somewhat easier problem. We can count the revolutions of a wheel just like the speedometer in a car will give total distance traveled.

Now, actually we have a somewhat similar package which is used for wheeled vehicles. The Army utilizes it. We do not have to sense the accelerating forces, but just the revolutions of the wheel.

We have to combine this, though, with some direction reference so we know whether we are going north or east. And we have to combine this and a small computer to tell us where we have traveled. There is a somewhat similar package which has been developed and is being used—a land navigation system.

The fact that you do have wheels simplifies the problem quite a bit.

Mr. McDonough. In only one direction and that is up and down. And this would be up and down and forward and back as far as its stabilizing effect is concerned.

It would affect the vehicle going up and down and forward and back, would it not—this instrument would?

Dr. Litman. This one would have effects in all directions.

It tells motion in all three directions.

Mr. McDonough. Just to get my mind clear on its comparative use on a land-operating wheeled vehicle, do the snubbers or stabilizers on an automobile that allows the body to move up and down easily over bumps have a similarity to this insofar as its up and down operations are concerned, or to a vehicle in the air?

Dr. Litman. No; not really. The snubbers are just a means of, say, damping or limiting motion of an automobile. They do not actually sense the total amount of the motion and compute how far we have gone up or down.

Mr. McDonough. That is right.

Dr. Litman. The inertial guidance system will actually sense these accelerating forces and use them to compute how far we have traveled, again up, as well as in a sidewise direction.

Mr. McDonough. Then the ultimate purpose of this is for straight, level flight?

Dr. Litman. Not necessarily for straight flight. It can be used for any types of maneuvers at all. If you want to go in one straight direction, you have to have some means of telling that you are going that way or not veering off to one side.

If you wish to go in a curved path—and here we can take as an example the satellites we have launched, which are first shot upward to the air and tilted over to get some circular velocity—the same system controls all those velocities; it controls the vehicle so that it acquires just the right motions in all directions.

We have to make slightly different provisions, depending on the purpose of the vehicle, whether it is to go on level flight or go into an orbit, perhaps to go to the moon. But the basic mechanism would always be the same, the means of sensing which way it is going in space.

Mr. McDonough. We haven't used this type of stabilizer on the satellites we have shot up to now, have we?

Dr. Litman. They have utilized a rather crude version of this. They have utilized some of the similar principles.

Mr. McDonough. Is this a patented article?

Dr. LITMAN. Yes. Much of the developments in this article are patented. The detailed items, generally, are all still classified. And most of the applications are for such items as our long-range ballistic missiles.

Mr. McDONOUGH. This is a product of American Bosch Arma Corp.?

Dr. LITMAN. That is correct.

Mr. McDONOUGH. For how large a vehicle could this act as a stabilizing unit in space flight? Would you have to build a bigger one than that for——

Dr. LITMAN No. The size of the vehicle is independent of the size of this guidance package. We, in fact, are striving—and other companies, in the field, similarly, are striving—to make smaller packages, so that they represent less weight and will not be any burden to lifting a payload into outer space.

The fact that it is smaller does not mean that it has any difficulty controlling a larger vehicle The controls of the vehicle are, for example, the engine nozzle, which will cause the engines to apply thrust in different directions

Mr. McDONOUGH. One last question: Is this completely automatic? You have dials to indicate these different motions, I suppose?

Dr. LITMAN The present use, of course, for example, on a ballistic missile is for an unmanned vehicle. Similarly, for the earth satellites. So, here we do have a completely automatic package. There are, in fact, no dials, since there is no one up there to read the dials. The information is used directly to steer the engines.

Mr. McDONOUGH. In a manned vehicle, would this be completely automatic?

Dr. LITMAN. In a manned vehicle, we would plan for this to be completely automatic since, the motions in taking off and landing are so rapid that they are really beyond the capabilities of a man to operate them. There would, in addition, be dials which he could look at so he would know where he is. But he would not have to, say, handle a steering wheel. This would all be done automatically.

The CHAIRMAN Mr. Hays?

Mr. HAYS. That is all I have.

Thank you, Mr. Chairman.

The CHAIRMAN. Mr. Natcher?

Mr. NATCHER. I have no questions, Mr. Chairman.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. I have no questions.

The CHAIRMAN. Mr Ford.

Mr. FORD. I have no questions.

The CHAIRMAN. Thank you very much, Dr. Litman. We are glad to have you before us We appreciate your testimony. Thank you very much.

Mr. LITMAN. Thank you.

The CHAIRMAN. The next witness is one of our colleagues. We are glad to have you before us, Congressman Harry G. Haskell, Jr., of Delaware. We are very glad to have you appear before us.

STATEMENT OF REPRESENTATIVE HARRY G. HASKELL, JR.,[41] OF DELAWARE

Mr. HASKELL. Thank you, Mr. Chairman. It is a pleasure to have this opportunity to testify before you today on this National Aeronautics and Space Agency.

During the past 2 years, I have been working with a team of 5 men on aviation's present problems and its future potential.

Last December, in a speech at the Franklin Institute in Philadelphia, I proposed the establishment of a national long-range program of research and study on the future utilization of airspace for peaceful purposes. Following that speech, Mr. Quesada, Chairman of the Airways Modernization Board, formed a panel of 12 extremely able and experienced aviation people to study that proposal.

The recommendations of these consultants to establish such a research program were presented to Dr. Killian, special assistant to the President.

Is there a need for civilian research agency? Research by the military in these areas must go forward at top speed, and there is no intent whatsoever in this legislation to have a new civilian agency direct military research efforts.

What is contemplated is an agency which can carry on research into the aspects of flight that have peaceful and scientific uses, and can work with and assist the military. As the military proceeds with its research, we would have a strong civilian research organization which could make use of knowledge developed by the military that has peaceful and scientific application, and an organization which could carry on flight research that does not directly interest the military.

It is realized that most of the testimony to date has been on space matters and the technical problem of how we can get a man to the moon. However, this proposed legislation is directed at research into the problem of flight within the earth's atmosphere, as well as space, and it is not limited to purely technical research on the problem of flight. These two very important points must not be overlooked, and I would like to direct my testimony to them.

There are two major areas of research on the problems of flight which will require extensive efforts.

First, there is the need for research into the purely technical problems. This is research to establish new technical capability. This research would deal with the vehicles, propulsion, equipment, and scientific know-how to enable man, physically, to use air and space.

Second, there is an urgent need for long-range research and study of nontechnical matters, such as the economic, legal, regulatory, and allied aspects of the advances in technical capability which will be made. As we develop new technical capability, we must undertake studies and research to see how it can be used and what problems it will create. For example, what will be the economic, legal, and

regulatory problems involved with new types of aircraft, satellites, new communications channels, weather operations, and the like. How can we control this new technology safely and efficiently?

On the problem of technical research, I have no competence whatsoever. On the other research areas, however, I do have some thoughts and ideas.

All the technical developments you can imagine might well be of little or no use to man if we do not simultaneously go to work on developing the means for him to utilize them and control them.

Our present national aviation program, unfortunately, provides solid evidence of how we have permitted our technical capability to outstrip our ability to use it fully, to control it, and to solve other related problems. Let me give you some specific evidence on this point.

The serious difficulties we are experiencing today in aviation are familiar to all of you. It is a fact that our air traffic control system is not nearly as safe or efficient as it should be. It is also a fact that we cannot make full utilization of even our present aircraft capability, and experienced persons in aviation today feel that we are years behind in this regard.

With respect to safety, the recent disastrous midair collision in Nevada was no surprise to anyone familiar with the situation. We have been experiencing about 3 or 4 near collisions in the air every single day, and it would take only about 6 collisions involving 2 airliners to exceed the accident rate of automobile travel.

With regard to efficiency, our inadequate air traffic control system is now costing the country about $60 or $70 million a year in delays of military and commercial aircraft.

But perhaps the most serious problem for all of us is the inability of the military to utilize fully its aircraft capability in the defense of the country. The information I have on this matter demonstrates the imperative need for research and study on control methods and the means of utilizing technical advances as they are developed.

Mr. Chairman, I believe this information bears directly on the deliberations of this committee.

Over the past 6 months, at my request, the Air Force and the Navy have provided me with 19 official reports on these aviation defense matters containing more than 120 pages of detailed information. Some of this information is secret; much of it is classified; and all of it is specific documentation of the critical military preparedness problems we face with respect to our airpower.

This brown envelope contains the classified reports to which I refer. While the reports are classified, I can discuss certain facts from them.

The reports make it unmistakably clear that our military preparedness against possible enemy attack is being seriously limited by our present inability to utilize fully the technical developments in our military aircraft.

First, active air defense scrambles to intercept unidentified and potentially hostile aircraft near or over the United States are severely delayed because our fighters are forced to fly rigid, roundabout courses from their bases to the unidentified bogeys.

Second, adequate combat training of Air Force and Navy pilots is seriously curtailed because operations at some of their bases are almost completely shut down under instrument flying conditions.

Third, the difficulty of controlling missile tests results in some tests being canceled and others being prohibited entirely because we cannot provide adequate clearance and safety for them.

Fourth, collisions and crashes of military aircraft amount to millions of dollars annually.

I want to emphasize that today these problems are not the fault of the Air Force, the Navy, or the Civil Aeronautics Administration which handles all military and civilian air traffic. All these organizations are working under the most extreme hardships, and are doing the best possible job with the equipment and the funds provided.

One of the most serious of these military situations is the limitation on our air defense and the use of our air defense interceptor aircraft. Every time the North American Air Defense Command launches an active air defense scramble under instrument conditions to intercept an unidentified and potentially hostile aircraft, the pilots of those fighters are delayed an average of 7 minutes and sometimes the delay amounts to as much as 20 minutes.

Mr. Chairman, according to the reports I have, there are 520 active air defense scrambles a month, and these delays represent an incredible situation. Most of us have always assumed that our fighters had a clear track after takeoff to get to the point of intercept as quickly as possible. That is not the case.

A 7-minute delay means that an enemy plane could get at least 70 miles closer to any one of our major cities.

A 20-minute delay would bring an enemy bomber 200 miles closer to its target. As you all know, with enemy planes today capable of delivering a hydrogen bomb attack, it does not require hundreds of planes to inflict terrible damage on us. A few bombers slipping through our air defenses on a sneak raid could cause millions of casualties. As General Power, commanding general of the Strategic Air Command, has said, "One enemy bomber can destroy one American city."

Let me describe a specific situation in more detail. In Delaware, we have had two fighter-interceptor squadrons assigned to help protect one of the most populated areas in the country along the Atlantic coast.

Every time an active air defense scramble was ordered at the New Castle Air Force Base which is now closed, the pilots had to detour on a prearranged course about 40 miles from a straight line to their targets to avoid the risk of collision with the heavy commercial and private airplane traffic flying on nearby airways.

This 40-mile detour represented about a 7-minute delay, and, of course, greatly reduced the range of the fighters by making them use up large amounts of fuel. The same type of situation exists at our other air defense base at Dover.

At Otis Air Force Base in Massachusetts, delays of scrambles at times amount to 20 minutes.

Mr. Chairman, I have proof in these reports that this situation exists at many locations throughout the country. While the CAA is trving to improve this situation, it has existed for a long time and it still operates this way.

What is most serious of all is the documented fact that in some cases our air defense fighters were completely unable to intercept unidentified and potentially hostile aircraft approaching the United States because they could not take a direct, immediate route to the target. I have specific details of these incidents in my possession.

A situation almost as serious in regard to our military preparedness exists in the limitations on the training of combat-ready fighter pilots and strategic bomber crews.

I have here a special report from the Strategic Air Command which shows that in 1957 SAC lost 2,160 hours of flying when they were prevented from getting their planes in the air because of heavy air traffic.

These 2,160 hours which were lost amount to the time required to train 11 B-47 crews from scratch. Last year, SAC had a net increase of only 55 crews brought up to combat-ready status from scratch.

In terms of maintaining the proficiency of existing SAC crews, these flying hours lost amounted to the time required to keep 142 B-47 crews at a fighting level. This command, it must be remembered, is our chief deterrent fence.

The Navy aviation problem in maintaining proficiency of its pilots is perhaps even more severe. One of the official reports from the Navy describes the situation as follows:

> As an average, naval air stations supporting the Atlantic Fleet can be expected to reduce operations to one-third or one-fourth under instrument conditions due to the delays and limitations of the air traffic control system. At least one station drop to a level far below this average.

I have reports containing specific information from each naval airbase on the cancellation of training missions.

Any loss in training to maintain combat readiness must be considered time lost forever. If an attack should come, we will have to fight with what we have ready to fight. There will not be time, as in previous wars, to hold off an enemy from our shores until we are trained to do the job.

We have received only a little information so far about the present or potential limitations imposed on missile tests by our air traffic control system. At one Navy test center, the report delivered to me shows that in a 3-month period, 72 missile tests were canceled because adequate control clearance could not be obtained. In 1 month the cancellations amounted to about 10 percent of the operations.

The contemplated testing of missiles over areas of the continental United States certainly raises all sorts of serious problems.

This training at actual missile defense sites near cities, according to Dr George E Valley, chief scientist of the Air Force, is essential to our combat readiness. How to provide a clear route through normal air traffic will be difficult to do, to say the least.

Finally, the losses to the Air Force from midair collisions and crashes are staggering. The Strategic Air Command in 1957 alone had 3 crashes which they attribute in whole or in part to the lack of an adequate air traffic control system which resulted in losses totalihg $11,420,000

These problems all stem from our inability to handle the technical capability of our aircraft. Our control systems have not kept pace with the development of faster and better airplanes.

We must not fail to learn from the experience we are going through today. It seems to me that these facts underline all too seriously the importance of conducting long-range studies on how we will handle new technological advances in flight both within and outside of the earth's atomsphere.

I cannot urge you too strongly to incorporate in this proposed legislation provision for long-range studies that will analyze the

problems and the opportunities which our technical advances will create.

Therefore, I would like to propose the following amendment to the draft bill which has been submitted to this committee. We have discussed this amendment with appropriate agencies in the Government including the Bureau of the Budget, and they have no objections to the inclusion of this amendment.

On page 2, line 18, insert the following:

(4) the establishment of long-range studies into the potential benefits to be gained from, the opportunities for, and the problems of utilizing manned and unmanned flight for peaceful and scientific purposes.

I believe that this new Agency would be the most appropriate organization to sponsor these studies, because the studies would be directed by the Agency which is conductong the technical research and close liaison could be maintained.

Thank you, Mr. Chairman, for the opportunity to present these views to this committee. I will be happy to supply, under appropriate security measures, any additional details on this military information that you may want.

The CHAIRMAN. Mr. Hays.

Mr. HAYS. Thank you, Mr. Chairman. I would say to our colleague that we appreciate his contribution to our thinking. We are glad to have you here. Mr. Haskell, you have introduced a bill on this subject?

Mr. HASKELL. I introduced a companion measure to this; yes.

Mr. HAYS. Is it in the same form as the chairman's bill?

Mr. HASKELL. Yes; it is.

Mr. HAYS. So, the amendment you propose would have to be added? In other words, it is not in the text of your bill?

Mr. HASKELL. No; it is not. It would have to be added.

Mr. HAYS. Thank you. That is all, Mr. Chairman.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. I have no questions, Mr. Chairman. But I want to thank our colleague, Mr. Haskell, for his appearance before our committee today.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. No questions.

The CHAIRMAN. Mr. McDonough.

Mr. MCDONOUGH. I appreciate your appearance here today, Mr. Haskell. I think you have made a very good point. We certainly can't apply too much research and study to the question of air traffic to create safety and to provide for additional military defense. I have no questions. I appreciate what you have said, though.

Mr. HASKELL. I used the air traffic control as an example of what we should have done in times past.

Incidentally, Prof. John Cooper was one of the members of our group who worked on this who I believe testified before you this morning.

The CHAIRMAN. Well, you have certainly addressed yourself to one of the most serious and challenging questions that confronts us—the question of air control. I have been very much interested in it for several years. I can see the development of military necessities and civilian necessities. I have often been interested in the reconciling of them rather than having conflicts, but to reconcile them to the advantage of our people both from a civilian and from a military angle.

It is a very serious problem. You have addressed yourself to a very challenging problem to Congress and to our people. You said you discussed the amendment with appropriate agencies in the Government including the Bureau of the Budget. Could you state for the record what agencies you discussed your proposed amendment with?

Mr. HASKELL. Yes. I checked with the National Advisory Committee. I checked with Jimmy Pyle of the CAA; with General Quesada of the Air Modernization Board; and with Dr. Killian's office.

The CHAIRMAN. You have done a lot of work. Are you satisfied that this language, if incorporated into the bill, would give this new Agency the authority to look into this field?

Mr. HASKELL. Yes, sir; I think it would make provision in the policy statement to go into long-range research, to look ahead.

The CHAIRMAN. Mr. Feldman.

Mr. FELDMAN. Just one question on one slight point. You stated the "establishment of long-range studies." Do you want to change that to "the establishment of continuous studies"?

Mr. HASKELL. Well, I would hate to change the language after going through all of those organizations. But I think the word "long-range" is pretty critical in my estimation. One thinks of fundamental research, basic research, as other substitute words. But we really are thinking in terms of long-range continuous studies.

That would be O. K. But I would not want to lose the word "long-range." Because I think that is a key word in what I am talking about.

The CHAIRMAN Well, wouldn't the establishment of studies include both immediate and long-range?

Mr. HASKELL. Conceivably it could. But my emphasis in this testimony is to point up the need for long-range studies looking ahead. Rather than say applied research or short—well, maybe it is semantics we are arguing about here.

Mr. FELDMAN. That is all; yes.

Mr. HASKELL. But the main thing to do is to look ahead and get the most competent people we can get to do these kinds of studies.

Mr. FELDMAN. In other words, spread the immediate and long-range studies?

The CHAIRMAN. Wouldn't the establishment of the studies include both? I would think so, Congressman.

Mr. HASKELL. It would include both.

The CHAIRMAN. Long-range might be considered as a limitation in case they felt that the matter should be looked into in the near future.

Mr. HASKELL. Let me put it this way: I think that long-range can be interpreted from 1 minute from now on up.

I would like to leave the emphasis on looking way ahead on this problem rather. I am sorry to disagree with you.

Mr. FELDMAN. We are not disagreeing; we are just exploring.

The CHAIRMAN No, not disagreeing. I am asking these questions to try and make your language stronger, the effects of it stronger in operation.

Mr. HASKELL. I appreciate that.

The CHAIRMAN. I just want to get your opinion, because "long-range" might be a direction that they could really take up studies in research in this field 2, 3, 5, 10 years off. Whereas, there is a solution to an immediate problem called for, isn't there?

Mr. HASKELL. Well, yes. I feel that the emphasis should be, though—when these people let out contracts on future work that is going to lead them into fields—if there is a scientific breakthrough somewhere, then we do a study on something that is going to happen some period of time ahead.

And if we can come up with a study that indicates that a problem is going to happen 5 years from now, then we do something about it now. And I am not really arguing against you. I am just—I still feel I would like the emphasis on the "long-range" because this is the—I think all the consultants feel that this is where the emphasis should be placed.

Mr. SISK. Apparently the word "long-range" is the significant word in your amendment to use. Is that right?

Mr. HASKELL. Well, it is to me.

Mr. SISK. Of course, as you know, now included in the bill down at the bottom of page 5 under "Functions of the Agency" is the following:

> To plan, direct and conduct the scientific studies and investigations of the problems of manned or unmanned flight within or outside the earth's atmosphere with a view to their practical solution.

Now, would you make the comparison with that language as against the language you have proposed here to be added to the policy statement?

Mr. HASKELL. I think you could carry out these functions within that language.

I think we are talking about the same one.

Mr. SISK. I am referring to the bottom of page 5, under the second section there, where the "Functions of the Agency" are set out. I was curious to determine what broader basis for study or broader direction you would assume to be included in your proposed amendment, as against what actually amounts to the spelling out of the function of the agency in the present bill.

Mr. HASKELL. I personally would not object to putting it in the function area, more or less similar verbiage, if you chose to do that.

It would strengthen what I would be trying to do. So, you are right in that suggestion.

Mr. SISK. I actually was not proposing necessarily to change and put it under the functions. As I understand this, you propose this as part of the policy?

Mr. HASKELL. That is right.

Mr. SISK. The point I had in mind was what more would the language that you propose do in the way of spelling it out?

Mr. HASKELL. I would say that I think you can do it within the function area. I would like the emphasis in the policy area so that the intent of Congress would show to the NACA and the board who are going to be directing these long-range studies that this is the intent of Congress that they do these long-range studies.

Mr. McDONOUGH. Let me say that I appreciate your point of view and your interest in this very much, Mr. Haskell. And insofar as the use of words in describing the intent of yourself and others whom you have consulted, if your amendment read "the establishment of continuous long-range studies"——

Mr. HASKELL. That would be fine.

Mr. McDONOUGH. Instead of "the establishment of long-range continuous studies"—"continued long-range studies" would carry out the intent of your bill.

That means that the purpose and intent is to study this thing out and get a long-range study started immediately.

Mr. HASKELL. I think you should take it either way. I would like to see the studies carried on continuously.

Mr. McDONOUGH. Yes.

Mr. HASKELL. I am not sure you would necessarily keep the same project going if you exhausted its possibilities.

The CHAIRMAN Now, if you put this in the declaration of purposes, would the language over on page 5 that Mr. Sisk was calling attention to—the language on page 5, of course, means to "plan, direct and conduct scientific studies and investigations of the problems of manned or unmanned flight within or outside the earth's atmosphere with a view to their practical solution."

Mr. HASKELL. That is broad enough, I think, to get the policy under it.

The CHAIRMAN. That means immediate and continuous.

Now, if your language is put into the declaration of purposes—I realize that your language may not come necessarily within the purview of this.

Mr. FELDMAN. It could be a substitute provision, and more properly belong in the text of the law itself.

Mr. McDONOUGH. Yes. Rather than the policy.

Under the title of "Functions" rather than "Policy." But you say to refer to it in "Policy" and put it in the law also?

Mr. HASKELL. I would be willing to have it in both. I think you can accomplish your objective if you put it in the "Policy." You could probably accomplish your objective if you put it just in "Functions."

Mr. FELDMAN. From the point of view of draftsmanship, you could refer to it possibly in the "Policy" and then set out the substantive provision where it belongs, under the "Functions."

Mr. HASKELL. You probably know more about that than I would.

The CHAIRMAN. Well, coming back again to "long-range": we have "the establishment of continuous studies." I can see that.

Mr. McDONOUGH. Continuous studies could be studies not of a long-range nature. But "continuous long-range" studies would be continuously looking forward to bettering the safety of air traffic.

That is my interpretation.

Mr. HASKELL. Yes. Of course, I am not just talking about air traffic here.

The establishment of "long-range" studies and potential benefits to be gained for the opportunities for and the problems of using manned and unmanned flight. The whole shooting match.

Mr. McDONOUGH. That is right.

I do not mean air traffic alone.

The CHAIRMAN. Well, why don't the provisions of page 5 cover what you have in mind?

Mr. HASKELL. I think it is conceivable that they do.

But I would like to keep the emphasis as a result of my language in the policy declaration. So that as you carry out the functions on page 5, there is that sense of direction given to the new board.

The CHAIRMAN. Yes. But if you put this in the policy declaration, it might then be connected up with the language in page 5 and treated as a limitation of the language in page 5.

In other words, page 5 doesn't provide for long-range—"plan, direct and conduct long-range scientific studies."

Mr. HASKELL. If you feel it is a limiting thing, I would suggest that you take almost this same verbiage and put it in as No. 3 or an extra number in "Functions."

Mr. FELDMAN. Professor Cooper made this suggestion.

I just went down to see him.

Turning again to section 6 (a) under "Functions":

(1) Develop a comprehensive program of research in the aeronautical and space sciences;

And this is what would be added:

And other subjects consistent with the declaration of policy in section 2

Mr. HASKELL. I think that would be just the place for it if you were going to put it in, right there.

And I would not object to what Professor Cooper has to suggest.

In fact, I would welcome it.

The CHAIRMAN. We all compliment you for this research work you have done and the study you have given to it.

And we compliment you on your whole presentation this afternoon.

My only concern was that I didn't want to find by inserting it we are eliminating the agency in certain respects.

Mr. HASKELL. I wouldn't want that either, Mr. Chairman.

The CHAIRMAN. We thank you very much for your presentation, Congressman Haskell.

Mr. HASKELL. Thank you very much, Mr. Chairman, and members of the committee.

Mr. FULTON. May I add my compliments to your statement, Mr. Haskell.

Mr. HASKELL. Thank you.

The CHAIRMAN. Mr. Keating, did you want to ask any questions?

Mr. KEATING. No. Only to compliment Mr. Haskell on his statement.

The CHAIRMAN. The committee will have a short executive session.

(Whereupon, at 4:30 p. m. the committee proceeded into executive session.)

ASTRONAUTICS AND SPACE EXPLORATION

THURSDAY, MAY 8, 1958

HOUSE OF REPRESENTATIVES,
SPECIAL SELECT COMMITTEE
ON ASTRONAUTICS AND SPACE,
Washington, D. C.

The committee met, pursuant to call, at 10:25 a. m., in the caucus room, Old House Office Building, the Honorable John W. McCormack (chairman of the committee) presiding.

Present: Representatives McCormack, Keating, Fulton, Natcher, McDonough, Ford, Brooks, Hays, O'Brien, Metcalf, and Sisk.

The CHAIRMAN. The committee will be in order.

The first witness is Mr. Andrew Haley, president of the International Astronautical Foundation.

We are very glad to have you appear as a witness, Mr. Haley.

Do you have a prepared statement?

Mr. HALEY. Yes, I have. I think it has been distributed to the committee.

The CHAIRMAN. You may proceed, Mr. Haley.

STATEMENT OF ANDREW G. HALEY, PRESIDENT INTERNATIONAL ASTRONAUTICAL FEDERATION

Mr. HALEY. Mr. Chairman and members of the committee, my residence and curriculum vitae are contained in an attachment to this statement. I will not read the biographical material, but I would appreciate your kindness in including it in the record.

The CHAIRMAN. It will be included in the record.

Mr. HALEY. In addition thereto I would like to point out that shortly after World War II broke out I was inducted into the Service and was appointed Chief of the Military Affairs Division in the Office of the Air Judge Advocate. At the request of scientists associated with the California Institute of Technology, Gen. H. H. Arnold released me from the military service to become president of Aerojet Engineering Corp., which I had previously founded in Pasadena, Calif., for the purpose of making rocket motor and propulsive systems.

I served as president until after V–E Day. I point this out merely to indicate that I have worked with my hands in rocketry and that I am not solely a legal theoretician.

Incidentally, the great British rocket inventor, William Congreve, was also a lawyer.

To complete the record I also append to this statement a bibliography of my recent writings.

I just want to make the record perfectly clear what my past activities in the field were.

I listened yesterday to the testimony and examination of Prof. John Cobb Cooper and the Honorable Loftus Becker, legal adviser to the Department of State. I have no comment to make on the testimony of Professor Cooper other than to say that I thoroughly agree with his statements, except in some very minor respects which I will not dwell upon.

With respect to this latter statement I would like to state that in my day and generation, this is like a young lawyer 25 years old saying that he disagrees with Chief Justice Hughes or something of that nature. Because throughout the world there is no more revered or respected legal personality than Prof. John Cobb Cooper. And when I say I disagree with him on some minor matters, it is only with respect to administrative details.

Professor Cooper is world renowned and revered.

Fundamentally, I also do not disagree with most of what was said by Mr. Becker. I desire to impress upon the committee that I am commenting on Mr. Becker's testimony from memory, as I do not have a copy of his statement or a transcript of the testimony, and if I have misunderstood his statements I hope to have the opportunity to file corrections.

I had to give a lecture last night at New York University and I left the hearing room and dictated this on my way. And it was reproduced this morning. Therefore, I have had no further opportunity to look into the matter.

My impression is that the first half of Mr. Becker's statement is really inconsistent with the second half. I ask you to reread his statement in the light of this analysis. I think Congressman Hays sensed this problem when he commented on differences between civil and military legal disciplines

I also think Congressman Sisk sensed the problem. In the first half Mr. Becker commented critically on many viewpoints, most of which I have enunciated. However, I think his comments are based not on legal considerations, but rather on political considerations. With respect to political considerations I am wholly incompetent to make judgments, and Mr Becker is one of the most competent.

This is the crux of the matter This is apparent from the fact that Mr. Becker quotes article 51 of the United Nations Charter relating to the inherent right of nations to defend themselves against armed attack

In my writings I have wholly ignored political considerations and I have especially ignored that classical ultima ratio of international politics—namely, warfare War is the last resort, the ultimate decision, and I have ignored that stark decision as not being within the science of jurisprudence, but as being the final consideration of politics.

War is not my problem while I am considering jurisprudence.

If any nation in the world projects a military missile over the United States without our permission, whether it be at an altitude of 1,000 feet or 1,000 miles, I would hold that this is wholly outside the law and is an act of war. The viewpoints criticized by Mr. Becker, in my opinion, are wholly sound, in that they relate to peaceful and civilian legal concepts rather than to military and political concepts. In the second half of his paper Mr. Becker does dwell upon civilian and peaceful aspects of the problem of space jurisdiction and I think that

most of his conclusions are quite correct and are inconsistent with his earlier thinking. No lawyer could deny the right of the United States, or any other sovereign nation, to protect itself, and it is unthinkable that we would relinquish one iota of our sovereignty in this respect in outer space or anywhere else. But this committee or this witness is not considering at this time this vital inherent right. We are simply considering the normal establishment of jurisdictional boundaries, such as now exist, and also the establishment of civilian agencies, such as the NACA, ICAO, WMO, and so on.

I have good reason to believe, based upon a great deal of research effort made by many of the greatest theoretical physicists in the world, that it is quite unscientific to state that air as air extends 10,000 to 100,000 miles above the surface of the earth. I will discuss this point later.

Incidentally, with the permission of the chairman I would like to submit for the record a letter I just received from Dr. Eugene Sänger, one of the world's great experts in the field of upper atmosphere. This is one example. He is the famous Sänger who started the ICBM program for Germany, and he points out that he not only agrees with the viewpoints I am going to express here later, but he also says the Bonn Government of Western Germany, through Dr. Gerlach, the chief legal officer, also agrees with his viewpoints.

If I have your permission I will submit a copy of that letter to Mr. Feldman.

The CHAIRMAN Do you want to make it a part of your remarks?

Mr. HALEY. Yes.

The CHAIRMAN. Without objection, it will be made a part of your remarks in the record.

(The above-mentioned letter follows:)

FORSCHUNGSINSTITIT FÜR PHYSIK DER STRAHLANTRIEBE E. V. STUTTGART,
Stuttgart-Flughafen, April 9, 1958.

DR. ANDREW G. HALEY,
President of the International Astronautical Federation,
Washington, D. C.

DEAR ANDY: From the viewpoint of the engineer, the upper limitation of national sovereignty would seem rather suitable at an altitude between 40 and 55 miles, as follows from your, and Mr. von Kármán's suggestions.

Flying bodies relying solely on aerodynamic lift cannot rise above this limit, and it is only these bodies that can actually change their path at will, and thus are enabled to avoid obstacles, such as national boundaries, at will.

Above these altitudes, flying objects already follow predominantly paths of inertia which cannot anymore be governed at will. Thus, bodies, flying at such altitudes, cannot avoid national borders any more, try as they might. Jurisdictional lines extending beyond these altitudes therefore could render any flight impossible.

The engineer must thus demand the upper limitation of national sovereignty in that region, where, the predominantly aeronautical flight, due to decreasing density of air, changes into the predominantly ballistic flight. This is the case in the region between 40 and 55 miles' altitude, suggested by you and Mr. von Kármán.

As far as I know, Dr. Gerlach, principal officer for space travel in the Federal Department of Traffic at Bonn, has worked on these problems, and has apparently arrived at similar results.

Sincerely yours,

SÄNGER.

Mr. HALEY. As a private United States citizen I favor the international adoption of an agreement defining the jurisdiction of outer

space for the same reason as does Mr. Becker—namely, so that no other nation may prevent the United States from using outer space for peaceful purposes.

At the present time, as Professor Cooper has pointed out on several occasions, any nation could now stop such scientific research by simply protesting. Great Britain, the Dominican Republic, Haiti, and others, could stop our present operations at Cape Canaveral immediately. Before proceeding to a further detailed discussion I might add that the domestic, municipal statutes and laws of all the nations of the earth, in each case, provide that the sovereignty of each nation shall extend through airspace.

I have appended to this statement a compilation of the citations to these statutes.

I think this is the first in existence—the first such compilation.

I have been unable to find any statute in which sovereignty is extended above airspace. I repeat, airspace is airspace and air is air—air is not something else, such as hydrogen or oxygen atoms, nor is it the atmosphere of the sun, nor is air meteoritic dust. Under all rules of statutory construction we must consider air as air and airspace as airspace, not as something else. Dog is not wolf. Man is not ape. In high altitudes air may be extremely rarefied, and it is still air until atoms dissociate—but it is a substance which, no matter how rarefied, if condensed to sea level is still that which we breathe and which is viable.

We cannot leave the question of establishing the limits of sovereignty and the boundaries and jurisdiction in a perpetual vacuum, nor can we keep this question on a case-to-case basis. What is the jurisdiction of this Select Committee on Astronautics and Space Exploration?

Is it a meaningless thing? Is it nonsense?

What is the jurisdiction of the Senate Special Committee on Space and Astronautics? What is the jurisdiction of the Civil Aeronautics Board? What is the jurisdiction of the International Civil Aviation Organization (ICAO)? What will be the jurisdiction of the new agency which is intended to be created by Congress? What is the jurisdiction of the Advanced Research Projects Agency? How are we going to restrain 80 or 90 other countries from handling the problem of jurisdiction?

Never before in the history of mankind has the necessity arisen so quickly to state legal parameters in connection with a vast new area of social change. The legal problems presented by the advent of space flight have been climactic, and technology has far outstripped the formulation of the legal rules. The gap has widened to the point that the peace of the world may be threatened. I am grateful for this opportunity to express my views, and I am grateful to the Members of the House and Senate, and to the President and the Secretary of State for the expressions of their own awareness of the need for orderly solutions.

Indeed, I am grateful to be present at probably the most well-selected committee that this great institution, this great Congress, could afford a person to talk to.

In arriving at a level-headed statement of the jurisdiction of space law, the lawyer must turn for help to the physicist to ascertain just

where airspace ends. The sound scientist avoids legal interpretation, while at the same time making essential contributions by staying within his technical expertise, and keeping the lawyer well advised on appropriate physical phenomena. Such has been the most helpful role of Dr. Theodore von Karman.

Dr. von Karman has suggested practical methods of formulating the jurisdiction of airspace. By the same token the jurisdiction of outer space.

Last spring he delivered a paper at the University of California entitled "Aerodynamic Heating—the Temperature Barrier in Aeronautics." In that paper he had occasion to use a diagram made by Masson and Gazley of the Rand Corp. showing the possible ranges for continuous flight in the velocity-altitude coordinate systems.

Pursuant to von Karman's suggestion, I devised a diagram—figure 1—containing curves showing the high-altitude sounding rocket regime, the earth orbital satellite regime and the Kepler regime—earth escape velocity—and some supernumerary information, but most important is what we shall now call the Karman primary jurisdiction line.

To establish sound bases for demarcation of air and space jurisdiction, it is necessary to consider that the conditions for accomplishing aerial flight, that is, to circle at constant altitude, are weight equals aerodynamic lift plus centrifugal force. The aerodynamic lift decreases with altitude because of the decreasing density of the air and in order to maintain continued flight beyond zero air lift, centrifugal force must take over.

Consider the flight of Capt. Ivan C. Kincheloe, in which he took the X-2 rocket plane to 126,000 feet altitude. That is this cross-hatched area down in here. (Fig. 1.)

His flight was strictly an aeronautical adventure and did not partake of space flight. At the altitude indicated aerodynamic lift carries 98 percent of the weight and only 2 percent is centrifugal force, or "Kepler force."

It will be noted that in the corridor of continuous flight when an object reaches approximately 275,000 feet and is traveling at 25,000 feet per second, the Kepler force takes over and aerodynamic lift is gone. This is a critical jurisdictional boundary.

Figure 1 is intended to be illustrative. The Karman line may eventually actually remain as shown on figure 1—it certainly is staying there as far as my investigations are concerned—or, after due consideration, the line may be significantly changed. In any event, this is the line at which airspace terminates.

Any such definition should be finally promulgated through the United Nations or by multilateral treaty arrangements and implemented by the International Civil Aviation Organization (ICAO).

Along the same line you are now utilizing the NACA.

(Figure 1 follows:)

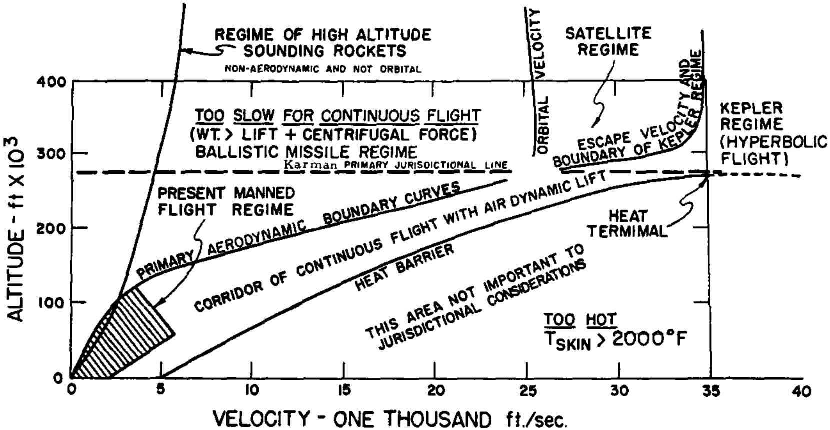

FIGURE 1

DIAGRAM SHOWING REGIMES OF ATMOSPHERIC AND EXTRA-ATMOSPHERIC FLIGHT AND DEPICTING THE JURISDICTIONAL BOUNDARY LINES

HALEY EXTRAPOLAT.

In determining the Karman line, the United Nations and ICAO will require the advice of a committee in stating the final definitions and in drafting detailed regulations. The basic statutes of ICAO will have to be broadened by international agreement and the name undoubtedly must be changed.

Just like you change the name of the agency in the NACA.

The first important action taken so far was the establishment in Barcelona by the International Astronautical Federation of the Cooper Committee, headed by world-renowned Professor John Cobb Cooper, and which will consist of three lawyers and four physicists who will define airspace and space jurisdiction.

I am advised by Professor Cooper that due to the inability of the committee to get together for other reasons that he may desire to resign as head of this committee.

He was unanimously appointed chairman of the committee because he was the best-qualified man in the world, the best lawyer, we thought, in the world to head the committee. And if for reasons now he cannot continue on as head, well that is something we can't help.

It would be senseless to build a surface trans-Atlantic steamship to perform the undersea functions of a submarine. The functions of the aircraft and the rocket ship are essentially even more disparate. In arriving at a reasonable Karman line, physicists and lawyers inevitably will reach agreement as to the point where the aeronautical vehicle no longer may perform efficiently and within reasonable physical and engineering parameters. It may be useful to examine, momentarily, some of these parameters.

A. M. Mayo has pointed out that control of the pilot's immediate environment from the standpoint of pressure and composition would become increasingly difficult as a function both of the length of time of flight and of the pressure reduction and change of atmospheric composition.

He goes on to state that at altitudes below approximately 70,000 feet the problem of pressurization and composition is taken care of relatively easily by pressurizing outside air. At higher altitudes, pressurization of outside air becomes increasingly difficult both from the standpoint of the power required and from that of handling the very high temperatures resulting from extreme ratios.

He also states that as outside pressures become negligible with respect to cockpit pressure, the problem of explosive decompression or even gradual loss of pressure becomes so acute that until pressurized cockpits are as highly reliable as the wings and basic structure of present aircraft, we will need to provide some sort of pressurization safety equipment.

Mayo states that information on the intensity and scope of cosmic radiation, together with data on their effect on human beings, is needed by the engineer Questions as to the possible existence of dangerous levels of radiation, such as X-rays from the sun, should also be surveyed. No completely practical approach to methods of protecting occupants of aircraft against high-energy radiations has yet been outlined. The problems might be reasonably simple were weight not such a primary consideration in all aircraft design problems.

Many other considerations will enter into the final determination of the Karman line, such as the danger of material collisions with the

airframe, escape problems, the problems posed by combined stresses and multifold fundamental questions of the construction of aircraft, as such, will all enter into the final decision.

H. Strughold points out that with increasing altitudes, some of the biological effects creep in gradually, while others rise at sharply defined levels. On the whole, the road from the surface of the earth to free space displays characteristic ecological stages. These stages are determined by the functions which the atmosphere has for man and craft.

He points out that we must first consider the oxygen component in the chemical constitution of the air. In this respect, only the lower half of the troposphere can be designated as the physiological atmosphere or the ecosphere of the air. It is in this narrow zone that the stage for the drama of life on our planet is normally set. Only this layer deserves the name "atmosphere" which, from the Greek word "atmos," means "breath."

E. O. Hulburt states that the region of the atmosphere from 0 to 6.2 miles, where the temperature falls rapidly with increase of altitude, has long been called the troposphere. The region from 33,000 to 66,000 feet, where the temperature is approximately constant, is called the stratosphere.

The ionosphere has its own well-accepted nomenclature, the terms D, E, F_1 and F_2 designating the four ionized regions with maxima of ionization at about 43.5, 62.1, 124.3, and 186.4 miles, respectively. Aside from these, there is no generally accepted terminology of upper atmospheric regions.

The terms "upper" and "outer" atmosphere are used with different meanings fairly elastic. The region from about 12.4 to 21.7 miles which embraces most of the ozone has been called the ozone layer or ozonosphere. It has been proposed that the region from the top of the stratosphere, at about 12.4 miles to the minimum of temperature, at about 43.5 miles be called the mesosphere and the region of increasing temperature, somewhere above 62.1 miles, the thermosphere.

The exosphere has been used to refer to the outer fringe of the atmosphere, where the air particles execute long elliptical orbits bouncing outward from impacts with other particles and falling back under gravity. In general, Hulburt concludes, the physical properties of the various regions are not yet well enough known to permit their fixation by an accepted terminology.

In their most recent writings, Cooper and Mayer have sought to locate airspace jurisdiction at a point in the ocean of air surrounding the earth where aerodynamic lift is gone. These authorities have avoided the mistakes of engineers and sociologists suddenly turned amateur lawyers who are attempting to locate airspace jurisdiction in such heterodox and altogether eclectic regions as the thermosphere, exosphere, mesosphere, and ozonosphere, even the nomenclature of which is doubtful, and none of which has any reference whatsoever to the problem at hand.

Under certain conditions national jurisdiction will be quite indirectly but effectively maintained over what is called by Professor Cooper "contiguous space." In the near future the nations of the earth will be offered point-to-point rocket communications involving many services.

The trajectories of each of these routes will be different, and will involve different altitudes. Some of these rockets will describe a trajectory requiring heights of 300 miles or less, and others will probably require heights in excess of 1,000 miles. National jurisdiction will be effectively maintained by the granting of launching and landing rights, and thus there will be indirect national control with respect to point-to-point earth rockets over contiguous space. With the advent of manned rocket ships, this control undoubtedly will become more severe because of vastly increased considerations of safety and other problems.

I hope you will listen to this because this goes right to the very fundamental of the goodness, the necessity, for the creation of your committee here. Your committee is essential.

The international regulation of point-to-point earth rocket vehicles will be under the jurisdiction of a successor international governmental organization to ICAO. The very problems of locating instrumentation along the manifold aerodynamic and nonaerodynamic routes, orbits and trajectories, will require the highest degree of international cooperation and regulation for the operational efficiency and safety of all concerned.

The aircraft, the point-to-point earth rocket ship, and the spaceship capable of freely maneuvering in outer space when navigating around earth or landing on earth, will each need navigation aids, anticollision devices, secondary radar, communications systems, meteorological services and many other international aids and services. In every instance of movement to or from any point on earth, the national licenses and permits which are the essential prerequisites of national society will be needed.

Mankind must mature appreciably to create an international authority having sole and complete jurisdiction over space flight and such an achievement must await the wise action of future generations.

We are simply not prepared for it today. That makes all the more important the domestic legislation that you enact and the domestic agencies that you set up.

No single nation has a paramount claim to outer space nor a monopoly on the scientific genius which will soon make its exploration and exploitation a reality.

The field of astronautics will progress only as international cooperation in the field is achieved.

National sovereignty ends for all purposes with the Karman line, and by adding by way of analogy the Stephen Decatur Doctrine demonstrated 150 years ago that:

The seas beyond reasonable coastal areas (space beyond the Karman line) are free and subject to control by no single despot or nation, and

The sponsors of ships at sea (spaceships in space) must be responsible for the conduct of their vessels.

More than 50 nations are participating in the IGY. This involves very extensive utilization of governmental and nongovernmental facilities and personnel. Active participation in the program is required of each nation, of its army, navy, air force, and coast guard personnel and facilities; of such governmental agencies as those concerned with standards, radar, radio, meteorology, weather, coast and geodetic surveys, geological surveys, and all types of official scientific and research organizations.

I point this out merely to indicate that I disagree here again with the testimony of Mr. Loftus Becker yesterday that the IGY was simply a little matter between a group of scientists who had no official capacities to do anything. I would like to point out that certainly the National Science Foundation is not unofficial—it receives its appropriations from Congress. I would like to point out, also that Mr. Eisenhower is still President of the United States. And he is the one who authorized the satellite program. And as far as the rest of the nations in the world are concerned, there is no question there, because in every other instance, the people who have authorized appropriations are those who are taking part in these enterprises and they are government employees and high officials of government.

Nevertheless if the United States Navy were not put to the burden of making the Vanguard from scratch and doing a great job of it as it was, I believe the job never would have been done. Some private scientists could not have built the Vanguard.

In addition, parallel, nonofficial institutions are involved, including universities and observatories in those few countries where such institutions are not owned and controlled by the state.

By agreeing to support actively the satellite program, the nations of the earth also agreed to the legal validity of the project.

Now this argument here is very attenuated. This is the substance of an article which was published by the Harvard Law Recorder. And it is annotated in the papers appended to my statement. Two or three say the argument is not valid. They have given no citations. I give hundreds of citations why the argument is valid.

I have heard many lawyers in and out of the Iron Curtain countries and Scandinavia and some of the great lawyers in Italy say the argument is valid. So, there you are

On the basis of sound principles of international law, the nations of the world may not protest the flight of nonmilitary artificial satellites over their territories when the purpose of such flight is the accumulation and dissemination of scientific data which shall be made available without restriction to all the nations of the world.

No single formal treaty emerged from the myriad agreements involved in the IGY. Nevertheless, a valid and binding world pact emerged from these acts of agreement and cooperation.

The international pact, in written form, may be abstracted from the thousands of documents and exchanges from which the living IGY has evolved There is nothing about a single formal treaty which makes it sacrosanct or makes it even an essential source of international law. In many instances the principles set forth in the treaty itself may have been established in international law long prior to the signing of the formal document itself. A rule of international law does not receive its validity from its enactment into a legal instrument such as an international law which is valid although not enacted in such legal instruments; and there are rules of international law which are not valid, although enacted in such instruments. Enactment, therefore, is no objective criterion for the alleged validity of a rule of international law.

The social scientists, just as clearly as the natural scientists—when I refer to social scientists, I mean a person who practices the science of jurisprudence—has the duty to acquire baseline data and then to implement such data in the dynamic evolution of society.

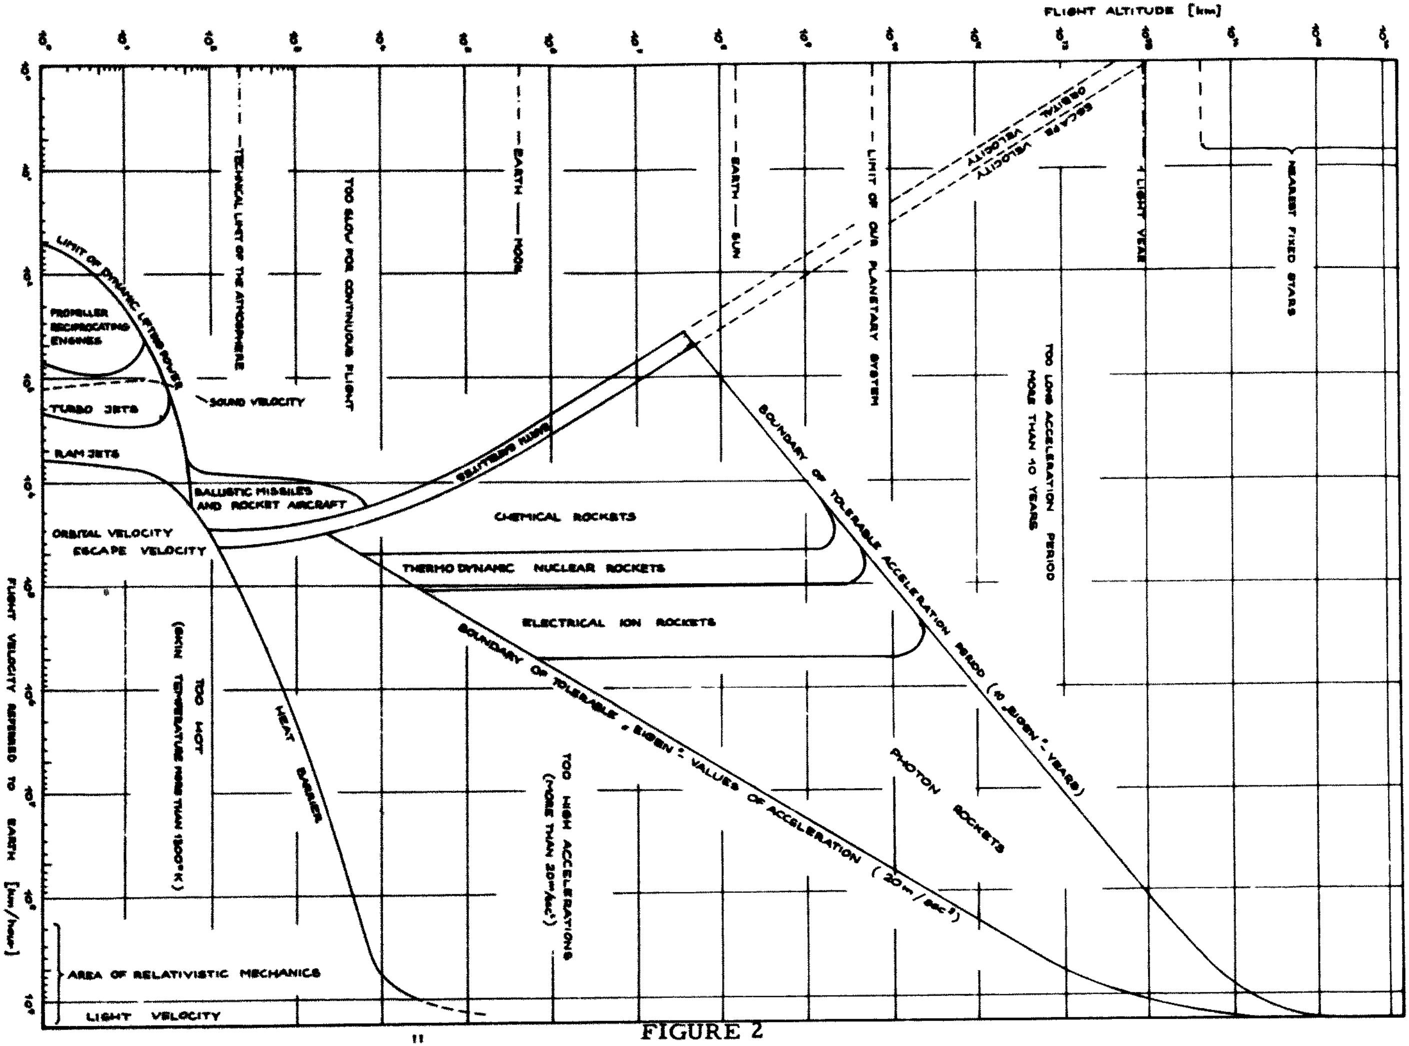

FIGURE 2

THE EUGEN SANGER SCHEMATIC DIAGRAM ILLUSTRATING ALL POSSIBLE TYPES OF FLIGHT REGIMES (ALTITUDE versus VELOCITY)

The advent of the rocket motor, with its potential of unlimited access on the earth and in space, presents a great new mutation requiring the immediate and careful attention of the social and natural scientists. The baseline material of the lawyer has always been invested in the mores of mankind from which it must extrapolate principles of justice.

As this is the Space Exploration Committee of the greatest legislative body in the history of humanity, I believe it is appropriate to point out that at this time we may postulate necessary rules of space exploration—namely, in any instance where there is reason to believe that intelligent life exists on a planet, no earth spaceship may land without having satisfactorily ascertained that (1) the landing and contact will injure neither the explorer nor the explored; and (2) the earth ship has been invited to land by the explored.

The regulation must be adhered to without exception, or we will project into space and perpetuate the bleak and devastating geocentric crimes of mankind. Further, we must conquer certain problems of semantics before we are worthy of space travel beyond our solar system.

This principle is just as old and simple as the basic idea of justice itself. It is a kind of compact not to harm or be harmed.

The Golden Rule has no application whatsoever in the field of metalaw. In metalaw we deal with all frames of existence—with intelligent beings different in kind. We must do unto others as they would have done unto them. To treat others as we would desire to be treated might well mean their destruction. We must treat them as they desire to be treated. This is the vastly significant premise of metalaw.

Metalaw was earlier defined as the law governing the rights of intelligent beings of different natures and existing in an indefinite number of different frameworks of natural law. An intelligent multidimensional creature would probably be so inferior as to require most considerate and sympathetic understanding and treatment by a three-dimensional universe, such as we conceive of mankind. The intelligent mankind concept runs into deep trouble vis a vis an intelligent two-dimensional creature existing in a three-dimensional continuum and problems of metalaw become truly complicated when one considers a man's relationship with intelligent two- and one-dimensional creatures existing in a two- or one-dimensional universe.

With the assistance of Dr. Eugene Sänger and Dr. Irene Sanger-Bredt the possible types of flight regimes, including those regimes which might philosophically spell the elimination of a dimension were illustrated by a diagram (fig. 2). Within this coordinate system, the domains of aeronautics, the transition domain from aeronautics to astronautics and the domain of astronautics are plotted.

(Fig. 2 faces this page.)

Mr. HALEY. Within this coordinate system, the domains of aeronautics, the transition domain from aeronautics to astronautics and the domain of astronautics are plotted.

Proper aeronautics, characterized by air-breathing propulsion systems, reaches up to about 50 miles. It lies between the two well-known limiting curves—namely, the limit of aerodynamics lifting power and the heat barrier. This domain plot shows an onion-peel shape (attaching one onion-peel to the next by increasing flight

velocities and altitudes) when progressing from propeller reciprocating engines to turbojets and then to ramjets.

Though aerodynamic lifting power is gradually replaced by the centrifugal force from the trajectory curvature beyond a velocity of 62,000 miles per hour, the intersection of the curves of limit of aerodynamic lifting power and heat barrier is nevertheless physically real and constitutes as the utmost limit of the ramjet also the definite limit of aeronautics.

Contrary to this, ballistic rockets and rocket aircraft are not limited by the limit of aerodynamic lifting power due to their "nonair-breathing" propulsion systems and they can fully exploit the lifting support of the inertial forces due to the trajectory curvature from about 3,730 miles per hour on, so that their possible altitudes of flight increase to several thousand miles and their flight velocities approach orbital velocity. The aerodynamic lifting power then is completely replaced by the inertial forces of the circular orbit about the earth.

These ballistic missiles and rocket aircraft form the transition domain from aeronautics to astronautics which flow into the domain of pure astronautics with the reaching of the orbital velocity. Hence, only a very small corridor connects aeronautics with astronautics.

Within the narrow band between orbital velocity and the constant—2-times larger escape velocity lie the artificial satellites on the earth.

This band curves to decreasing flight velocities with increasing altitude due to the decrease of the gravitational acceleration by the square of the altitude over the earth.

Beyond this band there open the immense vistas of interplanetary, interstellar and intergalactic space flight, in a structural shape surprisingly similar to that of aeronautics according to present concepts.

Thank you.

(Curriculum Vitae; Contributions on Space Law, etc.; International Astronautical Federation Bulletin, follow:)

CURRICULUM VITAE

Andrew G. Haley (1735 De Sales Street NW., Washington, D. C.) president of the International Astronautical Federation and general counsel of the American Rocket Society, was born in Tacoma, Wash. (November 19, 1904), and was educated at George Washington University (A. B. degree) and Georgetown University (LL. B. degree). A lawyer by profession, he has devoted a major part of his lifetime to "working with his hands in rocketry" and to practicing law in the technical fields, namely, radio, television, hydroelectric power, and in all branches of rocket propulsion. Prior to World War II he was counsel for the Federal Communications Commission. He was cofounder, president, and managing director of Aerojet Engineering Corp. (now the world's largest rocket company) during the period of World War II He was lecturer, First Jet Propulsion School, organized under military orders (1943). After he resigned as president of Aerojet, he served for a year as adviser on aircraft to the United States Senate Special Committee Investigating the National Defense Program and wrote a report for that committee urging Congress to stepup support of rocket research and development.

He served as legal adviser to the 87-nation International Telecommunication Conference at Atlantic City in 1947, and to the Fourth Inter-American Radio Conference in Washington, D. C., in 1949 He served as industry adviser to the Third North American Regional Broadcasting Conference at Montreal in 1949 and in Habana and Washington, D. C., in 1950; the Mexican-United States Broadcasting Conference in Mexico City in 1954 and in Washington, D. C., in 1955. He attended as observer the NATO Guided Missile Symposium in Munich,

April 23–27, 1956; the Sixth General Assembly of the Advisory Group for Aeronautical Research and Development (AGARD) to NATO, in Brussels, August 29–31, 1956; the Eighth Plenary Assembly of the International Radio Consultative Committee (CCIR) of the International Telecommunication Union (ITU) in Warsaw, August 31–September 5, 1956; the Ninth International Congress of Applied Mechanics at the Free University of Brussels, September 5–9, 1956; the Comite Special de l'Annee Geophysique Internationale (CSAGI) in Barcelona, September 9–12, 1956; the Guided Missile Seminar Guided Missile Committee of the Aircraft Industries Association (AIR) in Venice, September 24–27, 1956; and the Ninth Session of the UNESCO General Conference in New Delhi, November 9–18, 1956. He participated (as a member of the Human Factors Panel) in the Astronautics Symposium held in San Diego, Calif., February 18–20, 1957, under the sponsorship of the United States Air Force Office of Scientific Research and Convair Division of General Dynamics Corp. He organized and attended meetings of the members of the International Affairs Committee of the International Astronautical Federation and their consultants with officials of UNESCO in Paris, France, April 15–16, 1957.

In 1951 he was an American Rocket Society delegate to the Second International Astronautical Congress in London and was elected vice president of the International Astronautical Federation (IAF), to which office he was reelected at the Third Congress of the IAF held in Stuttgart in 1952 and at the Fourth Congress of the IAF held in Zurich in 1953. As vice president of the IAF he attended the Fifth Congress held in Innsbruck in 1954, and he attended the Sixth Congress of the IAF held in Copenhagen in 1955 as chairman of the delegation from the American Rocket Society. He was chairman of the International Affairs Committee and a member of the Finance Committee of the IAF until taking office as president. He was chairman of the delegation from the American Rocket Society to the Seventh International Astronautical Congress (IAF) held in Rome in September 1956, and to the Eighth International Astronautical Congress held in Barcelona October 7–12, 1957.

Mr. Haley was vice president of the American Rocket Society in 1953 and president in 1954. He served as a director of the American Rocket Society, 1951–52, and was reelected a director for the period 1955–57. He was the first chairman of the ARS Committee on Space Flight in 1952 and served again as chairman in 1953. As president of the ARS in 1954, he submitted a proposal to the National Science Foundation to sponsor a study of "The Utility of An Artificial Unmanned Earth Satellite," prepared by the Space Flight Committee. In January 1956, he was elected chairman of the board of directors of the American Rocket Society, a post to which no other director has been elected.

The membership of the American Rocket Society on December 2, 1954, presented Mr. Haley with a special award in the form of an engraved plaque "in appreciation for distinguished service and untiring efforts on behalf of the society during his term as president."

In 1953 he established by endowment the American Rocket Society Astronautics Award. The recipient in 1954 was Dr. Theodore von Karman; in 1955, Dr. Wernher von Braun; and in 1956, Dr. Joseph Kaplan.

He is a member of the Institute of Aeronautical Sciences, Society of Motion Picture and Television Engineers, Radio and Television Executives Society, Inc., Radio Pioneers, American Rocket Society, American Society of International Law, American Astronautical Society, American Television Society, American Bar Association, District of Columbia Bar Association, Federal Communications Bar Association, Federal Bar Association, Bar Association of Tennessee (honorary) Delta Theta Phi legal fraternity, Associatione Italiana Razzi, Dansk Interplanetarisk Selskab, Deutsche Gesellschaft fur Raketentechnik und Raumfahrt, Deutsche Arbeitegemeinschaft fur Raketentechnik, Japan Astronautical Society, Nederlandse Vereniging voor Ruimtevaart, Norsk Astronautisk Forening, Oesterreichische Gesellschaft fur Weltraumforschung, Svenska Interplanetariska Sallskapet, Sociedade Interplanetaria Brasileira, Société Francaise d'Astronautique, Fellow of the British Interplanetary Society, South African Interplanetary Society and of the Sociedad Argentina Interplanetaria; and honorary member of Schweizerische Astronautische Arbeitsgemeinschaft. Mr. Haley is vice chairman of the newly created Committee on Space Law of the American Bar Association.

He is the author of numerous articles published in Jet Propulsion, Harvard University Law Record, Tennessee Law Review, Journal of Air Law and Com-

merce of Northwestern University, Technical University of Stuttgart, Institute of Air Law at the University of Cologne, and of numerous other learned organizations. A book, Law of the Space Age, is about to be published by Public Affairs Press, Washington, D. C.

The International Astronautical Federation

Andrew G. Haley, President, International Astronautical Federation

The International Astronautical Federation was founded in Paris, France, during the autumn of 1950. The annual congress of the IAF have taken place successively at Paris (1950), London (1951), Stuttgart (1952), Zurich (1953), Innsbruck (1954), Copenhagen (1955), Rome (1956), and Barcelona (1957).
The Federation is now composed of the following Societies:

Agrupacion Astronautica Espanola
American Rocket Society.
American Astronautical Society
Asociacion Argentina Interplanetaria.
Association Egyptienne Astronautique.
Associazione Italiana Razzi.
Astronauticko Drustvo (Jugoslavia).
British Interplanetary Society
Commission on Astronautics, USSR Academy of Sciences.
Dansk Interplanetarisk Selskab.
Deutsche Arbeitsgemeinschaft fur Rakententechink.
Deutsches Raketen und Raumfahrt Museum e. V.
Deutsche Gesellschaft fur Rakententechnik und Raumfahrt.
Japanese Astronautical Society.
Nederlandse Vereniging voor Ruimtevaart.
Norsk Astronautisk Forening.
Oesterreichische Gesellschaft fur Weltraumforschung.
Polski Towarzystwo Astronauticzne.
Schweizerische Astronautische Arbeitsgemeinschaft.
Sociedade Interplanetaria Brasileira.
Sociedad Interplanetaria Chilena.
Societe Francaise d'Astronautique.
South African Interplanetary Society.
Svensk Interplanetarisk Selskap.
University of Cuyo (Institution Member).

The Eighth International Astronautical Federation Congress may be characterized as having placed emphasis on the organizational and business aspects of the Federation Mr Joseph A. Stemmer, secretary of the Federation, immediately raised questions concerning the legality and propriety of actions taken during the preceding Congresses—a matter which is of real and legitimate concern to Mr. Stemmer because of his duty to conform the actions of the Federation to appropriate Swiss law.
The British delegation, under the leadership of Dr L. R. Shepherd, Mr. L. J. Carter, and the new chairman of the British Interplanetary Society, Mr. K. W. Gatland, formally moved for the creation of a committee to thoroughly correct and revise the constitution of the Federation. The basic British proposal was enlarged somewhat by the action of the delegates in adding thereto an opportunity for the consideration by the committee of entirely new additions to the constitution.

The resolution finally adopted provided that "There is hereby created an ad hoc committee consisting of six members who will be nominated and elected by the member societies, and one of whom shall be designated as chairman by the president, which will be known as the Committee on the Correction and Revision of the Constitution Each member society shall submit to the president on or before January 31, 1958, his recommendations for the correction and revision of the constitution. Each such recommendation shall be considered and finally disposed of by the committee, and brief reasons shall be given for every such action. The committee may take final actions by majority votes of a quorum of the membership thereof, and a quorum shall consist of three members of the committee. The president shall be an ex officio member of the committee and his presence at a meeting shall be counted in reaching a quorum. The committee shall meet in persona within 150 days from January 31, 1958, and it shall submit to the president before the next congress a corrected and revised constitution with brief statements of reasons for each such correction and revision. The president shall submit said report to qualified Swiss legal counsel for his opinion as to the legality of the corrected and revised constitution, and all pertinent documents will thereupon be duplicated and submitted to the member societies for further consideration "

The committee appointed by President Shepherd consists of A. G. Haley, chairman, USA, Fritz Gerlach, Germany; Alla Massevitch, U. S S. R; Georges Delval, France; L J Carter, England; and J. A Stemran, Switzerland.

In view of the legal complications and involvements which are bound to arise as the result of ventures into space above the earth's atmosphere, I suggested the creation of a committee "to define the regions of jurisdiction of air law, and of space law." By common consent Prof. John Cobb Cooper, general counsel of the International Air Transport Association and world-renowned international lawyer, was named as chairman of the committee, which has been designated as "the Cooper committee." The committee will submit its findings and recommendations to the Secretary-General of the United Nations. A slightly more detailed description of the committee is contained in my paper which was presented at the Barcelona Conference "I urge that at a plenary session of this congress, the president of the International Astronautical Federation be authorized to appoint a committee of 7 persons, consisting of 4 physicists and 3 lawyers, who will draft a definition of airspace and recommend a rule delimiting airspace jurisdiction, such definition and rule to be supported by a statement of findings of fact and conclusions of law. The resolution should be transmitted to the attention of the Secretary-General of the United Nations and to the Secretary-General of the International Civil Aviation Organization (ICAO), with the statement that the committee will cooperate with the appropriate officials of said organizations."

The president, Dr. Leslie R. Shepherd, decided that no person other than Prof. John Cobb Cooper should be appointed to this committee with the exception that the name of Dr. A F. Spilhaus, dean of the Institute of Technology, University of Minnesota, was generally agreed to, and it was also agreed that Dr Sedov would arrange for the appointment of two Soviet scientists to the committee. It was also felt that the USA should be limited to two members, the U. S S. R. to two members, and that the rest should be named from such countries as Great Britain, Germany, France, Italy, from South America, and so on. It was the general consensus of the Congress that the Cooper committee, in addition to defining air jurisdiction and space jurisdiction as an adjective task, should also undertake the substantive task of stating jurisdictional rules.

The assembled delegates were pleased to hear from Dr. W. Schwabl of Springer-Verlag, the publisher of Astronautica Acta, that his company would print the papers delivered at the Barcelona Congress. By unanimous agreement Dr. Friedrich Hecht was named again as chairman of the Astronautica Acta Committee, which is also the committee which finally passes upon papers to be delivered at the Congresses, and he was authorized by President L. R. Shepherd to name the other members of this committee. In addition to himself as chairman, Dr. Hecht appointed Dr. Wolfgang B. Klemperer as vice chairman, and Dr. Shepherd, Dr. Sänger, and Dr. Sedov. Any paper to be delivered at the Ninth Congress in Holland must be approved in writing by one of these committee members. This in no way interferes with the authority of any member society to screen the papers initially in its own right.

I was elected president for the ensuing year, along with the following vice presidents: Mr. A. Hjertstrand, Sweden; Dr. J. M. J. Kooy, Holland; Prof. Leonid I. Sedov, U. S. S. R.; Dr. L. R. Shepherd, Great Britain; Prof. T. M. Tabanera, Argentina; and Prof. K. Zarankiewicz, Poland.

No final proposal is on hand for the 10th International Astronautical Federation Congress. Dr. Sedov has tentatively suggested Moscow as the host city, but he must ascertain whether arrangements can be made and he will report the official Soviet action within 2 or 3 months. If Moscow is unavailable, the 10th Congress will be held in London. In 1960, the 11th Congress will be held in Stockholm. This is a firm commitment. It was suggested that in 1961 the 12th Congress be held in Washington, D. C. The ARS delegation made it clear, however, that approval of the board of directors of the American Rocket Society must be obtained before any final action may be taken.

This is the first time a representative of the social sciences has been elected president of the Federation. I was impressed with the general feeling among the delegates that they desired to utilize my organizational experience derived from 30 years' practice of the law, and they also were impressed by the fact that the legal problems presented by the advent of space flight have been climaceteric, and space technology has far outstripped the formulation of legal rules, and the gap has widened to the point that the peace of the world is threatened. I was deeply encouraged and moved to accept the presidency because of the level-headed action of the delegates in authorizing the creation of the Cooper committee.

I intend to make every effort to broaden the influence of Astronautica Acta, to increase its circulation, and to suggest to the Astronautica Acta Committee that the board of editors and the advisory board be maintained on a current working basis.

I also would desire to increase the "worthwhileness" of the annual congresses. I intend to suggest that for 4 days of the congress two nonconflicting sessions run concurrently during the morning and afternoons. So that each and every person attending the congress will be satisfied that the time was well spent, I am suggesting that I be authorized, on the basis of recommendations from the committee, to invite a guest speaker to be the head of, or keynoter, of each of the sessions. Such guest speaker would have practically unlimited time to deliver his original paper and the assembled scientists would have adequate time for questioning and comment. This would leave, out of each session, 2 hours for the presentation of additional papers, the only inhibition on the additional papers would be that each such paper must be approved in writing by one member of the committee.

There is also what is known as the Sanger-von Karman-Haley proposal to create in the Federation an academy of astronautics. Persons would be elected to the academy for life tenure, and there would be a rotating directorate chosen from the members of the academy. Only scientists of real accomplishment in the natural and social sciences would become members of this academy. The administrative and executive activities of the Federation would be discharged by the council, as at the present time, but all actions taken by the officers would be subject to the general supervision and control of the academy.

66. YUGOSLAVIA

A. Statute: (1) Law of February 22, 1928 (Sluzbene Novine of the Kingdom of the Serbs, Croats, and Slovenes, No. 50–XIII, 1928, amended by Law of January 14, 1930, ibid, No. 18–VII, 1930). (2) Decree on Civil Aviation, 1946 (Official Gazette of FPRY, No. 47, 1949).

B Treaty: (1) Convention Relating to the Regulation of Aerial Navigation, Paris, October 13, 1919, (11 League of Nations Treaty Series 173); ratified in 1926 (Sluzbene Novine of the Kingdom of the Serbs, Croats, and Slovenes, No. 8–II, 1927). (2) Convention on International Civil Aviation, Chicago, December 7, 1944 (U. S. treaties and other international acts, 1591, 1947); ratified 1953 (Official Gazette of the FPRY, Appendix—International Treaties No 3, 1954).

I would like to point out that the work of this committee—I would point out that the very elan, the very interior feeling of the legislative body which had reason to create this committee in itself is enough justification for serious consideration of these problems we have posed here today.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. This committee has received testimony to the effect that the satellites placed in orbit by the Soviet Union during the present geophysical year were probably in compliance with the usual provision made in such cases. But after the close of the geophysical year we will have another question.

What will take place, in your opinion, Mr. Haley, if no agreement is reached with the Soviet Union or the other countries of the world at the close of the geophysical year concerning research, experimentation, and the use of satellites and rockets and missiles from the standpoint of experimentation? What is going to take place?

Mr. HALEY. This is a most heartening question, because I think it is the vital problem that faces us.

And I think it should be one of the major problems for the consideration of the Committee on Astronautics and Space Exploration. In my article in the Harvard Law Record, I maintain that during the course of the international geophysical year that the nations of the world have agreed to this matter, to this proposal; but you can scarcely extend it beyond the international geophysical year, because the basis of exchange of representations was made because of the international geophysical year.

I am very much concerned that we must have at least interim understanding among the nations that these scientific explorations may continue. But we must sort of work for that end objective almost immediately.

Mr. NATCHER. What suggestions do you have to make concerning the procedure we should follow in obtaining that objective?

Should it be through the United Nations organizations? What should be the procedure?

Mr. HALEY. I personally—and I am speaking as a private citizen, of course—have a feeling that you are taking the right action now in the present bill you have proposed to enact, as at least a first measure, by utilizing the existing NACA agency and broadening it.

And I think, therefore, that we should, if possible, proceed through the United Nations. It may be necessary to call a mutilateral treatymaking proposition. But, on the other hand, we have a good forum—the United Nations—I wouldn't disagree with Mr. Fulton's proposals, but personally I would utilize the machinery of the United Nations, but not the Disarmament Commission.

Mr. NATCHER. Thank you, Mr. Chairman.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. Mr. Haley, of course the thing I am concerned with in this matter is how far do you propose that we go—and I am speaking now unilaterally—to set up rules and regulations for our own use or benefit in the control and launching of satellites or space exploration or of the landing or taking off of spaceships, as a unilateral proposition?

That is, I mean how far do you anticipate that we can go without some type of multilateral program developing?

Mr. HALEY. That is the point. Of course, all I can say now is pretty primitive.

I can say that I am thoroughly happy with the creation of this Committee on Astronautics and Space Exploration and the hearings you have held, and so on, and your proposals for investigation of problems. But certain problems have not yet arisen.

I think you should have study groups to consider the future problems of space travel and of the earth-to-earth, or point-to-point earth-rocket travel. And I think that you are providing for that—so I do not think you can do anything more at the present time unilaterally than to study the inevitable problems and be prepared to handle such problems on the basis of sound solutions. Law must precede man into space.

Mr. SISK. Well, I appreciate your statement. And looking over some of the background here, I, of course, am familiar with the fact, and I understand it, that you are quite recognized in the field of this type of law which is still in its infancy, to some extent. Yet we have in the immediate future a problem facing us.

And realizing the difficulties involved in international agreements of any kind today, with reference to attempts to disarm, and so on, I can foresee, let's say, next year, a possibility arising. And I was curious whether you had any recommendations on how far you would go in setting up a specific regulation?

Mr. HALEY. Mr. Sisk, you gave me the finest question that I could have and I thoroughly muffed it. I apologize.

I can give you an example that is so cogent and right down the line of your thinking that it is amazing that I am so stupid as not to grasp your question immediately.

That is the question of radio regulation.

Right now under the thesis that there has been a subsisting treaty—at least an agreement among nations—whereby the orbiting is lawful; by the same token you cannot do anything unlawful in orbiting. In other words, you cannot violate the treaties of the world; you cannot violate the domestic municipal law of any nation, and so on.

The first violation in space law occurred in connection with Sputnik I and II. This matter is within the realm of my own expertise, so to speak, for 30 years. The Russians used the frequency 20.005 megacycles, and the frequency 40.002 megacycles for dissemination of signals from satellites to earth.

Now, under valid existing treaties, the International Telecommunications Convention, to which Russia is a signatory, you must file at Geneva your choice of—the selection of frequencies and the proposed use. And you must not select any frequency that has already been filed upon and which will conflict with the allocations made by the ITU—the International Telecommunications Union.

So, what happened?

The Russian Sputnik, No. I, violated the use of 20.005 by one of the most essential United States station, namely, WWV, in Maryland, which is the great calibration station of the United States.

In other words, it is almost impossible for me to describe its importance, because it is the time signal station, timed to the sixth digit.

It is a station that calibrates meters—electronic meters, radio meters—and a thousand other things which are essential to the scientific community of America, and this station should not be interfered with.

All right, that is only one example. Others I won't take the time of the committee in describing.

40.002, another channel, that is used in region 2 of the world—I think that is in southern Asia—for radio dissemination in connection with the safety of life and property in the air, you see. And there it might have caused interference.

And there are claims of interference in other parts of the world; which I won't go into.

I have it all written out. I won't bore the committee with it.

Now, another thing is that RCA in New York and the Australian Government simultaneously recorded on tape a signal on 14.836, or some 14-something, megacycles which appeared to be a questioning signal from the Soviet to the satellite.

In other words, this signal seemed to be asking for information from the satellite, and receiving information from the satellite station, you see. What goes on: That is the sort of signal.

Now, we know nothing about this other than the very strange concomitance of two great radio centers hearing the signal at the same time.

That use, of course, would be another violation.

So already we have violations of space law. And I must say that these violations are receiving the active attention of our governmental agencies. And that the whole problem of space law in this field is being attended to as best they can by our governmental agencies. For example, the Federal Communications Commission has two proceedings pending. And it has issues in each proceeding concerning the use of radio signals for space purposes. And I have appeared on both those proceedings And these are justifiable proceedings. So there we are doing something nationally.

Also the State Department has a working group preparatory to the revision of the 1959 Radio Convention in Geneva, looking now into the communications problems of space travel. I think this is one of the duties of this committee to look into this too.

Mr. SISK. I yield to counsel.

Mr. FELDMAN. Mr. Haley, in your prepared statement you stated that under the International Geophysical Year—and correct me, if I am wrong—that we had something in the nature of an international pact, and that was, in effect, an agreement.

Now, if that, in effect, was an agreement, then under it, the sending up of the sputniks could be justified. Is that not so?

Mr. HALEY. That is my point exactly

Mr. FELDMAN. Well, then, can you reconcile the statement that it was justified with your reply to Congressman Sisk's question just now and say that was a violation of an international agreement?

Mr. HALEY. No.

Thank you for giving me the opportunity to clarify that point. What I said—at least what I should have said—was that sending up the sputnik was justified—Sputnik, the object itself, you see. But by the very fact of its legality there was a concomitant duty on the part of the persons who sent it up to obey the laws of all nations, other laws.

Now, there are thousands of other laws. One of them is the laws relating to radio disseminations. Radio disseminations really have nothing to do essentially by themselves in the orbital object going around. But if they use that object for an unlawful purpose or if they use it unlawfully, then they have violated space law.

Mr. FELDMAN. That isn't quite clear to me.

Mr. FULTON. Actually what you mean, Mr. Haley, is that where there is no rule or regulation already set out in outer space, there probably is, by custom, already established among the nations through the IGY, a set of rules.

But you also made the point that, where there is at present an international agreement, such as under the Telecommunications Union, and there are regulations already set up, there has been a violation in that field.

Mr. HALEY. That is right, that field alone.

Mr. FULTON. You were referring to two separate fields?

Mr. HALEY. That is right.

Mr. FELDMAN. Well, that would be one rationale. But the other could also be that once you say this was legal, once you say they had the authority to send this up, then you can also conclude that they had the right to do so. Under the Geophysical Year they had the authority, implied authority, to transmit the messages as they saw fit, providing they make those available eventually to the scientific community.

You can take both sides of that question, and you can not resolve it. You can not resolve it by saying that you disagree, because there is just as potent an argument on one side as there is on the other.

Mr. HALEY. I disagree with that too. Your flag carries a responsibility.

Mr. FELDMAN. I don't see where that is an answer to it at all. I can see perfectly clear that we are getting into a hairsplitting argument here. The reason we are getting into it is because there is a basis for both sides.

Mr. HALEY. Yes, sir. The view may well be taken that all treaty law must be specifically extended to outer space—this view is quite valid.

Mr. FELDMAN. And because you have a basis for both sides you may not be able to resolve the fact. We know this in law, for example, that where there is a dispute on a scientific question, and where there is a difference of opinion between the two, you can not resolve the fact. That must be precisely the situation here.

Mr. SISK. Mr. Chairman, as a layman over here, if I can make a comment. I realize these two lawyers here, of course, can have a difference of opinion. I have many very fine friends who are lawyers. But as a layman, I would understand from Mr. Haley's answers, if I may be able to give a layman's example, that I am permitted, if I own an automobile and have a license, to drive it on the highways, but I am still required to comply with the rules of the road while operating the vehicle.

Is that an oversimplified explanation of your position, Mr. Haley? That Russia had a right under IGY agreements to launch a satellite; but that there were certain rules and regulations, rules of the road, so to speak, that they were supposed to comply with in the use of it? Is that applicable at all?

Mr. HALEY. That is one sound viewpoint, but Mr. Feldman also has a very good argument.

Mr. FELDMAN. All I am saying is that there is room for the other side.

Mr. SISK. I might say, of course, Mr. Haley, I have great respect for Mr. Feldman. He has done a great job for us. I am not agreeing or disagreeing with either of you gentlemen. I am trying to clarify in my own mind what I understood to be your position.

Mr. HALEY. That is my position. Mr. Feldman is indeed most competent and he also has a position which is highly defensible, and I concede he may be quite right.

Mr. SISK. Your position is that they had the right, more or less, under an international agreement, to launch a satellite, but they could still be required to comply with international law, for instance, in radio transmission or other uses.

Mr. HALEY. That is my point. On the other hand Mr. Feldman may be 100 percent correct, in that in outer space no law prevails and it may be necessary first to arrive at a system of treaty law before any violations may be said to occur.

Mr. FELDMAN. What could we do about it, if we wanted to do something?

Mr. SISK. That was the key question I had.

But, Mr. Chairman, that is all I have at the present time.

The CHAIRMAN. Mr. Fulton.

Mr. FULTON. I think there is a further point we should consider in line with the colloquy between you and Mr. Feldman. And that is as to the field of space flight by agreement under the IGY where it was preliminary agreed with Russia that the sputniks, Explorers, and Vanguards, for example, would go to a certain height.

I believe that, actually, when the Russians put their sputniks in the air—we have had previous testimony here that they went to a higher level than was either agreed upon or that the other nations expected. So if you are basing your philosophy on the fact that there was an agreement among nations through respected and authoritative bodies, rather than governmental bodies, in many cases, I would think that the agreements would have to be on what was intended and not just what happened. Possibly I think Congressman McCormack and I would both agree that even in the field of space flight there was possibly a violation to begin with by Russia on what was agreed as to the height of the sputniks.

Is that not right?

Mr. HALEY. I think so, yes.

Mr. FULTON. So that you might start on space travel with a violation on space flight as well as on telecommunications.

Mr. HALEY. I think that is a very important statement you are making, because after all if somebody posted a satellite at 22,500 feet orbiting over the earth, just watching Washington, that would be—at that point it could become stationary as far as Washington is concerned.

That is one of the problems that you face, you see.

Mr. FULTON. Another point is this: When Sputnik No. 1 was put in the air, the purpose was known. But as far as we were able to determine there was no communication of the intent or its practical use, so that we in the other countries, including the United States, didn't know what the scientific implementation was, did we?

Mr. HALEY. You are exactly right about that statement. We still don't know the answer to it.

We have statements back and forth. We have a lot of information.

Mr. FULTON. When we are looking at violations of the telecommunications point, actually under the agreements of the IGY. Any nation has until 1 year after the event to make known its full scientific information and results. Is that not correct?

Mr. HALEY. That is correct.

Mr. FULTON. So far as Russia releasing materials, she has been doing as she has been doing all along. Russia is, therefore, not technically in violation of any agreement under the Geophysical Year on the point of releasing scientific information.

Mr. HALEY. That is right.

Mr. FULTON. Then, on section 2 of article 2 of the United States Constitution, the power is given to the President of the United States, with the advice and consent of two-thirds of the Senate, to make treaties. There has, in addition to that, grown up a form of executive agreement. Under this, we in the United States, through agreements of less than treaty status, have certain pacts that are in operation and effect concerning various fields of lesser importance.

Are you inferring that the IGY type of agreement is of the treaty level? Or do you keep it down to the executive agreement level?

Mr. HALEY. I take it—that is a very good question. It certainly is not the treaty level. And it certainly is not in the executive-agreement level. It is part of the method of growth of international law, such as the law of the sea which is observed by all nations.

Mr. FULTON. May I then bring up this question.

In the common law which we have inherited, there is the basic rule of law that there is a basic unit. But we look in each separate instance to find what that unit is on an unwritten-law basis. Do you agree with that?

Mr. HALEY. Yes; I do.

Mr. FULTON. So that you really are saying that this is to be added——

The CHAIRMAN. Well, what about the uses of customs which develop into common law?

Mr. FULTON. That is a good point.

The CHAIRMAN. What customs have we got here that can develop a common-law status?

Mr. HALEY. That is the point of the Harvard article—the customs. This is by consent.

Mr. FULTON. I might say that I am speaking as a private citizen. I went to Harvard Law.

Mr. HALEY. I wanted to give you the reference to the articles.

Mr. FULTON. The point I am coming to is this: Shouldn't Congress have some statement of our intention in the United States as to what we will use outer space for, a statement of peaceful purposes.

Should we not begin with that basis?

Mr. HALEY. Absolutely.

Mr. FULTON. Then shouldn't we in this Congress say, by resolution, that we feel that this is important enough to have a national space agency to implement a national space policy?

Mr. HALEY. Exactly so.

Mr. FULTON. Then shouldn't we likewise say that we feel that the ramifications of it automatically go into international law of one kind or another. Shouldn't we recommend to the President that he proceed through the United Nations or other agencies, or multilateral international agreements arrived at a conference, to get some international agreement on the method for exploring outer space for the benefit of mankind.

Wouldn't you say that?

Mr. HALEY. I think you are expressing it far better than I could. It is what I want to say.

Mr. FULTON. You would agree with that?

Mr. HALEY. Absolutely. I not only agree with it, but I think it is expressing it in a perfect manner, yes.

Mr FULTON. Then, when we come to that point, we must decide what the Space Agency shall do. You would agree that it should be a civilian space agency, would you not?

Mr. HALEY. Oh, yes, by all means. I wouldn't limit the military, though, as a matter of fact The military function is something separate and distinct. The military should have all the support and freedom it needs to defend our country.

Mr. FULTON. As a matter of fact, in the legislation as drawn, on line 7 of page 2, it excepts specificially the activities as they may be peculiar to or primarily associated with weapons systems or military programs.

So you would agree with that.

Mr. HALEY. I agree with that absolutely.

Mr. FULTON. Now that brings up this point of difference between you and our good friend Loftus Becker. He refers to article 51 of the United Nations Charter and thinks that that might be the basis for a defensive approach to outer space. But isn't the problem both civilian research and development and exploration, as well as defensive?

And then shouldn't we proceed on both elements, one on the civilian and the second on defensive if we took either one, we are making a mistake, are we not?

Mr. HALEY. Well, absolutely. That is as logical as anything could be. The CAB, and the CAA, those two agencies don't interfere with the military. They still have an essential function to perform, just like the agency you are talking about has an essential function to perform.

Mr. FULTON. On that end of it, when I asked Mr. Becker yesterday about what there might be previously to give Congress the right to go into outer space, presuming it was on a civilian basis, he had spoken of the commerce power.

Now, that is section 8 of article 1 of the Constitution where Congress has the power to regulate commerce with foreign nations and among States.

You wouldn't base our policy that narrowly, that we were simply going out under the commerce power of the Constitution, because that is too narrow a civilian point of view, is it not?

Mr. HALEY. I think so, yes. The commerce clause is pertinent but by itself, altogether too narrow.

Mr. FULTON. Would you have this civilian Space Agency set up as one director or as a commission form?

Mr. HALEY. At the present time I think we stand on the same situation as in 1910 with respect to radio, you see. I think what you are doing now is all right for now. But this is a first step. Later on when we have point-to-point rocket operations on the earth itself, when we have some civilian uses for satellites and outer space and so on—which won't be too long from now—then we will have to have commissions set up such as we now have with respect to the CAB and the CAA.

And I don't think that an advisory board like NACA would be effective later on. It is all right now.

Mr. FULTON. That brings me to my final point.

You do recommend Congress setting up a national space agency.

Mr. HALEY. Yes.

Mr. FULTON. Because we are going to be asked by other Members of the Congress and by taxpayers why not let it go just as it is and why run into the expense and the added redtape of a new agency.

Do you believe there should be a new separate agency, a space agency?

Mr. HALEY. No; I didn't say that. I said at the present time we should proceed with the program that you have undertaken under the law here, under the bill here.

Mr. FULTON. The point is shall we set up a national space agency as a separate agency or simply leave it in the NACA as it now exists?

The CHAIRMAN. You have read the bill, have you?

Mr. HALEY. Yes.

The CHAIRMAN. You mean you realize that this is terminating the NACA and using its facilities.

Mr. HALEY. Of course I realize that; yes.

The CHAIRMAN. And as the facilities and so forth—well, as the chief counsel says, the building block of the new agency—it is going to use that.

Mr. HALEY. Yes; I realize that. I think that is good.

Mr. FULTON. But you think it is important and urgent enough that we should proceed immediately to the setting up of a national space agency.

Mr. HALEY. Absolutely. I think it is essential.

Mr. FULTON. Thank you. That is all.

The CHAIRMAN. Any questions, Mr. Brooks?

Mr. BROOKS. No questions.

The CHAIRMAN. Mr. Feldman.

Mr. FELDMAN. Let me get back to your statement on page 13, that under international law no nation may protest the flight overhead of a scientific satellite.

This, at least in my opinion, is highly debatable. And Professor Cooper does not agree with this point of view. Sir Wilfred Jenks, on the other hand, has said the same thing on the basis of a tacit agreement and practice connected with the United States and Soviet satellites. Certainly, there is no treaty or executive agreement.

And Mr. Becker says that this tacit agreement is limited to the period of the IGY, since the advance announcements of the satellite launchings were so limited.

Now, the Cooper-Becker position seems to be legally sound.

On the other hand, you and Sir Wilfred Jenks may have been influenced by the fact that you want outer space to be free to all nations for peaceful uses.

Mr. HALEY. Yes; that is correct.

Mr. FELDMAN. And then, of course, there is also the analogy from the law of the seas, namely, the radio law that you have just alluded to. Now, I understand that you have attended a great many of the international conferences in this field for many years.

Mr. HALEY. All of them.

Mr. FULTON. And at those conferences have you had contact with representatives from the Iron Curtain countries, particularly Russia? Have they discussed scientific matters at those conferences?

Mr. HALEY. That is a very good question. I would be very happy to answer it.

Here is U. S. A.–U. S. S. R., you see. Well, the first time that Professor Leonid Sedov, Chairman of the Astronomical Unit of the Academy of Sciences, U. S. S. R.—Professor Sedov—let's say he sits here. We are both together all the time at these conferences.

The first Congress he came to was at Copenhagen in 1955, just after President Eisenhower announced the satellite program.

They invited the chiefs of delegations to the Soviet Embassy. And I went there as chief of the American Rocket Society, the American delegation.

Professor Ogorodnikov, who was chief astronomer at Leningrad, said that—he volunteered on that occasion that he had already calculated the orbit of a satellite.

The CHAIRMAN. The question was: Was there a free exchange of conversation of views?

Mr. HALEY. Not exactly. As far as I was concerned on no occasion in any Congress have I ever asked a question of any Iron Curtain delegate. I never asked any questions. I did not want to be impertinent, you see, in the sense of putting them on the spot.

The CHAIRMAN. Well, I would do it.

Mr. HALEY. Yes. But I was an official of the entire organization.

The CHAIRMAN. There are various ways of finding out both affirmatively and negatively. You can learn information in many ways.

Mr. HALEY. I just wanted to make the point that I do not ask what might be considered to be impertinent questions.

The CHAIRMAN. Did you find a cooperative spirit?

Mr. HALEY. No.

The CHAIRMAN. There was a holding back?

Mr. HALEY. Just a silence.

But there was, however, enough information for us to have realized what Russia was doing.

The CHAIRMAN. Well, you can learn from silence.

Mr. HALEY. That is what I will tell you. The first thing was that Ogorodnikov said he had calculated the satellite orbit.

The CHAIRMAN. If we are going to vote for a certain bill and you look at me and don't say anything, I am learning something. I say, well, I have got a little difficulty there.

Mr. HALEY. That is the reason you are the leader of the House.

On that Congress we learned that they had calculated the orbit of a satellite.

Mr. FELDMAN. When was that?

Mr. HALEY. 1955, just after the announcement of President Eisenhower.

Mr. FULTON. Who said it?

Mr. HALEY. Professor Ogorodnikov, just a few days after the President's announcement. Nobody paid a darned bit of attention to it as far as I was concerned. To me it was an immense fact. I reported it all over. But I was told "the Russians are boasting again."

The CHAIRMAN. They weren't taking you in; were they? I mean not you but——

Mr. HALEY. Well.

Then, to return their compliment, I gave a party for them with the chiefs of delegations in my suite in my hotel.

Professor Sedov, who was Chairman of the Astronautical Commission of the Academy of Science of the U. S. S. R., made a few remarks stating the fact that they thought that this was no great problem; that they had enough basic things in the works to put a satellite up, and they were very happy that Mr. Khrushchev had approved the program. They had been permitted for the first time to come to our meetings, you see. So they wanted to collaborate in this IGY proposition.

All right, their next episode was——

Mr. FULTON. What was the date of that?

Mr. HALEY. 1955.

Mr. FULTON. What time of the year?

Mr. HALEY. August. Just after the President's announcement. That was July 29, I think. About 10 days after. This was the first time they had come, you see.

This is the old story of the barn door being opened and the horse leaving, and so on.

So, in Rome in 1956, Professor Sedov said that he thought our proposed satellite was very small, and that the Soviet satellite would be much larger. And he said that he thought we were having long delays. And there was no reason why there shouldn't be a satellite launched very soon, you see.

This again was, to me, immense news. And simple news, but immense. If you want to expand upon it a thousand different ways, you still come back to the same thing. Our satellite was too small; their's was larger; we were too slow; they would be faster, you see. That drew comments from various sources that "Oh, they are boasting again, you see."

They are still boasting.

Of course, the next episode of the International Conference was in—on the way with Dr. von Karman we heard the news in Toulouse that the sputnik was out in outer space.

But now the concomitance of these things is such that there should have been absolutely no—if they were critically analyzed there should have been no doubt in the minds of the officials, the appropriate officials of America, that the Russians were going to launch a satellite and they were going to launch a big satellite.

Mr. BROOKS. We were just overconfident, a little blase.

Mr. HALEY. To say the least, yes.

The CHAIRMAN. Mr. Haley, of course we all know, whether lawyers or nonlawyers, there is the law of self-preservation. That is the leading question that anyone can answer. And, of course, until there are satisfactory international arrangements made we cannot ignore the law of self-preservation in the national interest and security of our own country. That is so, isn't it?

Mr. HALEY. I should say it is so.

The CHAIRMAN. The importance of the military is always great. Particularly in days like this we cannot ignore the significance in the terms of not only our own preservation but the preservation of a culture and ideals and principles, and the deepest things we stand for—the intangibles

That is true, isn't it?

Mr. HALEY. I would agree with that.

The CHAIRMAN. These questions don't contradict anything you have said. You recognize that the field of international settlement is a long one; and as in other human matters, an ever-changing and an endless one But precedent helps future negotiations, and conversations, and negotiations, and so forth.

But during that we cannot—we must always at all times recognize the law of necessity which follows the law of self-preservation.

That is correct, isn't it?

Mr. HALEY. That is absolutely correct. That is what bothered me about the testimony yesterday. Because I think that we will soon—soon we will become a second-rate nation overnight unless we are well ahead in the technology for peaceful purposes for mankind everywhere.

The CHAIRMAN. But during that period, we cannot ignore the exigencies of the law of self-preservation.

Mr. HALEY. I certainly agree with that statement.

The CHAIRMAN. Any further questions?

(No response.)

The CHAIRMAN. Thank you very much, Mr. Haley. We have enjoyed your appearance before us.

The next witness is Mr. Leonard Niederlehner of the Department of Defense.

I understand that you have Col. Sidney Rubenstein, Deputy Director of Personnel Security Policy, with you.

Do you want to start off like a panel? We like the informal atmosphere because we think we get more information.

We are very glad to have both of you gentlemen with us.

Do you have prepared statements?

Mr. NIEDERLEHNER. We do not, Mr. Chairman. I was notified just this morning. If you will give me an indication of what you

would like to have me address myself to, I think I can do it without a formal statement.

Mr. FELDMAN. The purpose of having these two gentlemen here this morning is so we can have the directives concerning the classification and declassification of classified material in the record. And also an explanation in a general way of how material is classified and unclassified.

Do you have those records with you, sir?

Mr. NIEDERLEHNER. I do; yes, sir.

STATEMENT OF LEONARD NIEDERLEHNER[42] DEPUTY GENERAL COUNSEL, DEPARTMENT OF DEFENSE, ACCOMPANIED BY COL. SIDNEY S. RUBENSTEIN. DEPUTY DIRECTOR, PERSONNEL SECURITY POLICY OFFICE OF THE SECRETARY OF DEFENSE

Mr. NIEDERLEHNER. I think, perhaps, from the committee's point of view, you would be interested in the distinction between the classification system which applies in the Department of Defense, for example, and that in the Atomic Energy Commission.

In the Atomic Energy Commission there is a specific legal basis for the classification of restricted data.

Mr. FELDMAN. A provision.

Mr. NIEDERLEHNER. In the Department of Defense, the authority to classify is derivative, and is based upon a number of much more general provisions of the law. The specific basis upon which the system is now working is an Executive order of the President which is numbered Executive Order 10501, dated November 5, 1953. This, in turn, is elaborated and applied within the Department of Defense in a Department of Defense directive applicable throughout the entire Department. It is numbered 5200.1. And this is dated July 8, 1957.

Regarding the general basis of the classification of information, there are a number of background provisions of law and the Constitution which are generally pointed to as the basis for this classification of defense information.

First is a housekeeping statute which makes the head of an agency responsible for the preservation of the material which is entrusted to his care by virtue of the fact that he is the head of the agency.

The CHAIRMAN. Is that the old statute?

Mr. NIEDERLEHNER. That is the old title 5, United States Code, section 22. This is one of the bases of the responsibility of the head of the agency for the preservation of information.

There is also the Espionage Act, which is title 18, United States Code, section 793, and the following sections. This statute makes a criminal offense of the release of certain information to unauthorized persons. And from that you draw the substantial inference that the individual who has custody must preserve it.

I think you could go further back into the general responsibility of the Commander in Chief, for example, to preserve military information because military information by its very nature in relation to

[42] Niederlehner, Leonard (nē-der-lā-ner), lawyer, b Cincinnati, Oct. 12, 1914, s. Louis William and Agnes (Clark) N.; LL. B., U. Cincinnati, 1937; m Helen Virginia Warfield, July 2, 1948, children—James, Barbara. Admitted Ohio bar, 1937, practice of law, Cin , 1937–40, sec. Congressman H. S Bigelow, 1938, office of gen. counsel Fed. Security Agy., 1941, counsel bur. yards and docks Navy Dept., 1946–47, munitions bd Office Sec. Def , 1948-52, asst. general counsel, 1952-53, deputy general counsel, Department of Defense, 1953–. Served as lt. comdr U. S. N. R., 1942–46. Mem. Am. Legion, Order of Coif. Home. 4031 N. 35th St., Arlington, Va. Office: Office of Secretary of Defense, Washington.

conduct of warfare must be preserved to prevent an advantage to a potential enemy.

If you wish, I will offer for the record the Executive order of 1953.

The CHAIRMAN. Without objection it will be made a part of the record.

(The above-mentioned order follows:)

EXECUTIVE ORDER NO. 10501, NOVEMBER 5, 1953, SAFEGUARDING OFFICIAL INFORMATION IN THE INTERESTS OF THE DEFENSE OF THE UNITED STATES

Whereas it is essential that the citizens of the United States be informed concerning the activities of their government; and

Whereas the interests of national defense require the preservation of the ability of the United States to protect and defend itself against all hostile or destructive action by covert or overt means, including espionage as well as military action; and

Whereas it is essential that certain official information affecting the national defense be protected uniformly against unauthorized disclosure:

Now, therefore, by virtue of the authority vested in me by the Constitution and statutes, and as President of the United States, and deeming such action necessary in the best interests of the national security, it is hereby ordered as follows:

SECTION 1. CLASSIFICATION CATEGORIES

Official information which requires protection in the interests of national defense shall be limited to three categories of classification, which in descending order of importance shall carry one of the following designations: Top Secret, Secret, or Confidential. No other designation shall be used to classify defense information, including military information, as requiring protection in the interests of national defense, except as expressly provided by statute. These categories are defined as follows:

(a) *Top Secret.* Except as may be expressly provided by statute, the use of the classification Top Secret shall be authorized, by appropriate authority, only for defense information or material which requires the highest degree of protection. The Top Secret classification shall be applied only to that information or material the defense aspect of which is paramount, and the unauthorized disclosure of which could result in exceptionally grave damage to the Nation such as leading to a definite break in diplomatic relations affecting the defense of the United States, an armed attack against the United States or its allies, a war, or the compromise of military or defense plans, or intelligence operations, or scientific or technological developments vital to the national defense.

(b) *Secret.* Except as may be expressly provided by statute, the use of the classification Secret shall be authorized, by appropriate authority, only for defense information or material the unauthorized disclosure of which could result in serious damage to the Nation, such as by jeopardizing the international relations of the United States, endangering the effectiveness of a program or policy of vital importance to the national defense, or compromising important military or defense plans, scientific or technological developments important to national defense, or information revealing important intelligence operations.

(c) *Confidential.* Except as may be expressly provided by statute, the use of the classification Confidential shall be authorized, by appropriate authority, only for defense information or material the unauthorized disclosure of which could be prejudicial to the defense interests of the nation.

SECTION 2. LIMITATION OF AUTHORITY TO CLASSIFY

The authority to classify defense information or material under this order shall be limited in the departments and agencies of the executive branch as hereinafter specified. Departments and agencies subject to the specified limitations shall be designated by the President:

(a) In those departments and agencies having no direct responsibility for national defense there shall be no authority for original classification of information or material under this order.

(b) In those departments and agencies having partial but not primary responsibility for matters pertaining to national defense the authority for original classification of information or material under this order shall be exercised only by the head of the department or agency, without delegation.

(c) In those departments and agencies not affected by the provisions of subsections (a) and (b), above, the authority for original classification of information or material under this order shall be exercised only by responsible officers or employees, who shall be specifically designated for this purpose. Heads of such departments and agencies shall limit the delegation of authority to classify as severely as is consistent with the orderly and expeditious transaction of Government business.

SECTION 3. CLASSIFICATION

Persons designated to have authority for original classification of information or material which requires protection in the interests of national defense under this order shall be held responsible for its proper classification in accordance with the definitions of the three categories in section 1, hereof. Unnecessary classification and over-classification shall be scrupulously avoided. The following special rules shall be observed in classification of defense information or material:

(a) *Documents in General:* Documents shall be classified according to their own content and not necessarily according to their relationship to other documents. References to classified material which do not reveal classified defense information shall not be classified.

(b) *Physically Connected Documents:* The classification of a file or group of physically connected documents shall be at least as high as that of the most highly classified document therein. Documents separated from the file or group shall be handled in accordance with their individual defense classification.

(c) *Multiple Classification:* A document, product, or substance shall bear a classification at least as high as that of its highest classified component. The document, product, or substance shall bear only one over-all classification, notwithstanding that pages, paragraphs, sections, or components thereof bear different classifications.

(d) *Transmittal Letters:* A letter transmitting defense information shall be classified at least as high as its highest classified enclosure.

(e) *Information Originated by a Foreign Government or Organization:* Defense information of a classified nature furnished to the United States by a foreign government or international organization shall be assigned a classification which will assure a degree of protection equivalent to or greater than that required by the government or international organization which furnished the information.

SECTION 4. DECLASSIFICATION, DOWNGRADING, OR UPGRADING

Heads of departments or agencies originating classified material shall designate persons to be responsible for continuing review of such classified material for the purpose of declassifying or downgrading it whenever national defense considerations permit, and for receiving requests for such review from all sources. Formal procedures shall be established to provide specific means for prompt review of classified material and its declassification or downgrading in order to preserve the effectiveness and integrity of the classification system and to eliminate accumulation of classified material which no longer requires protection in the defense interest. The following special rules shall be observed with respect to changes of classification of defense material:

(a) *Automatic Changes:* To the fullest extent practicable, the classifying authority shall indicate on the material (except telegrams) at the time of original classification that after a specified event or date, or upon removal of classified enclosures, the material will be downgraded or declassified.

(b) *Non-Automatic Changes:* The persons designated to receive requests for review of classified material may downgrade or declassify such material when circumstances no longer warrant its retention in its original classification provided the consent of the appropriate classifying authority has been obtained. The downgrading or declassification of extracts from or paraphrases of classified documents shall also require the consent of the appropriate classifying authority unless the agency making such extracts knows positively that they warrant a classification lower than that of the document from which extracted, or that they are not classified.

(c) *Material Officially Transferred:* In the case of material transferred by or pursuant to statute or Executive order from one department or agency to another for the latter's use and as part of its official files or property, as distinguished from transfers merely for purposes of storage, the receiving department or agency shall be deemed to be the classifying authority for all purposes under this order, including declassification and downgrading.

(d) *Material Not Officially Transferred:* When any department or agency has in its possession any classified material which has become five years old, and it appears (1) that such material originated in an agency which has since become defunct and whose files and other property have not been officially transferred to another department or agency within the meaning of subsection (c), above, or (2) that it is impossible for the possessing department or agency to identify the originating agency, and (3) a review of the material indicates that it should be downgraded or declassified, the said possessing department or agency shall have power to declassify or downgrade such material. If it appears probable that another department or agency may have a substantial interest in whether the classification of any particular information should be maintained, the possessing department or agency shall not exercise the power conferred upon it by this subsection, except with the consent of the other department or agency, until thirty days after it has notified such other department or agency of the nature of the material and of its intention to declassify or downgrade the same. During such thirty-day period the other department or agency may, if it so desires, express its objections to declassifying or downgrading the particular material, but the power to make the ultimate decision shall reside in the possessing department or agency

(e) *Classified Telegrams:* Such telegrams shall not be referred to, extracted from, paraphrased, downgraded, declassified, or disseminated, except in accordance with special regulations issued by the head of the originating department or agency. Classified telegrams transmitted over cryptographic systems shall be handled in accordance with the regulations of the transmitting department or agency.

(f) *Downgrading:* If the recipient of classified material believes that it has been classified too highly, he may make a request to the reviewing official who may downgrade or declassify the material after obtaining the consent of the appropriate classifying authority.

(g) *Upgrading* If the recipient of unclassified material believes that it should be classified, or if the recipient of classified material believes that its classification is not sufficiently protective, it shall be safeguarded in accordance with the classification deemed appropriate and a request made to the reviewing official, who may classify the material or upgrade the classification after obtaining the consent of the appropriate classifying authority.

(h) *Notification of Change in Classification.* The reviewing official taking action to declassify, downgrade, or upgrade classified material shall notify all addressees to whom the material was originally transmitted.

SECTION 5. MARKING OF CLASSIFIED MATERIAL

After a determination of the proper defense classification to be assigned has been made in accordance with the provisions of this order, the classified material shall be marked as follows:

(a) *Bound Documents:* The assigned defense classification on bound documents, such as books or pamphlets, the pages of which are permanently and securely fastened together, shall be conspicuously marked or stamped on the outside of the front cover, on the title page, on the first page, on the back page and on the outside of the back cover. In each case the markings shall be applied to the top and bottom of the page or cover.

(b) *Unbound Documents:* The assigned defense classification on unbound documents, such as letters, memoranda, reports, telegrams, and other similar documents, the pages of which are not permanently and securely fastened together, shall be conspicuously marked or stamped at the top and bottom of each page, in such manner that the marking will be clearly visible when the pages are clipped or stapled together.

(c) *Charts, Maps, and Drawings:* Classified charts, maps, and drawings shall carry the defense classification marking under the legend, title block, or scale in such manner that it will be reproduced on all copies made therefrom. Such classification shall also be marked at the top and bottom in each instance.

(d) *Photographs, Films and Recordings:* Classified photographs, films, and recordings, and their containers, shall be conspicuously and appropriately marked with the assigned defense classification.

(e) *Products or Substances:* The assigned defense classification shall be conspicuously marked on classified products or substances, if possible, and on their containers, if possible, or, if the article or container cannot be marked, written notification of such classification shall be furnished to recipients of such products or substances.

(f) *Reproductions:* All copies of reproductions of classified material shall be appropriately marked or stamped in the same manner as the original thereof.

(g) *Unclassified Material:* Normally, unclassified material shall not be marked or stamped *Unclassified* unless it is essential to convey to a recipient of such material that it has been examined specifically with a view to imposing a defense classification and has been determined not to require such classification.

(h) *Change or Removal of Classification:* Whenever classified material is declassified, downgraded, or upgraded, the material shall be marked or stamped in a prominent place to reflect the change in classification, the authority for the action, the date of action, and the identity of the person or unit taking the action. In addition, the old classification marking shall be cancelled and the new classification (if any) substituted therefor. *Automatic* change in classification shall be indicated by the appropriate classifying authority through marking or stamping in a prominent place to reflect information specified in subsection 4 (a) hereof.

(i) *Material Furnished Persons not in the Executive Branch of the Government:* When classified material affecting the national defense is furnished authorized persons, in or out of Federal service, other than those in the executive branch, the following notation, in addition to the assigned classification marking, shall whenever practicable be placed on the material, on its container, or on the written notification of its assigned classification:

"This material contains information affecting the national defense of the United States within the meaning of the espionage laws, Title 18, U. S. C., Secs. 793 and 794, the transmission or revelation of which in any manner to an unauthorized person is prohibited by law."

Use of alternative marking concerning "Restricted Data" as defined by the Atomic Energy Act is authorized when appropriate.

SECTION 6. CUSTODY AND SAFEKEEPING

The possession or use of classified defense information or material shall be limited to locations where facilities for secure storage or protection thereof are available by means of which unauthorized persons are prevented from gaining access thereto. Whenever such information or material is not under the personal supervision of its custodian, whether during or outside of working hours, the following physical or mechanical means shall be taken to protect it:

(a) *Storage of Top Secret Material:* Top Secret defense material shall be protected in storage by the most secure facilities possible. Normally it will be stored in a safe or a safe-type steel file container having a three-position, dial-type, combination lock, and being of such weight, size, construction, or installation as to minimize the possibility of surreptitious entry, physical theft, damage by fire, or tampering. The head of a department or agency may approve other storage facilities for this material which offer comparable or better protection, such as an alarmed area, a vault, a secure vault-type room, or an area under close surveillance of an armed guard.

(b) *Secret and Confidential Material:* These categories of defense material may be stored in a manner authorized for Top Secret material, or in metal file cabinets equipped with steel lockbar and an approved three combination dial-type padlock from which the manufacturer's identification numbers have been obliterated, or in comparably secure facilities approved by the head of the department or agency.

(c) *Other Classified Material:* Heads of departments and agencies shall prescribe such protective facilities as may be necessary in their departments or agencies for material originating under statutory provisions requiring protection of certain information.

(d) *Changes of Lock Combinations:* Combinations on locks of safekeeping equipment shall be changed, only by persons having appropriate security

clearance, whenever such equipment is placed in use after procurement from the manufacturer or other sources, whenever a person knowing the combination is transferred from the office to which the equipment is assigned, or whenever the combination has been subjected to compromise, and at least once every year. Knowledge of combinations shall be limited to the minimum number of persons necessary for operating purposes. Records of combinations shall be classified no lower than the highest category of classified defense material authorized for storage in the safekeeping equipment concerned.

(e) *Custodian's Responsibilities*: Custodians of classified defense material shall be responsible for providing the best possible protection and accountability for such material at all times and particularly for securely locking classified material in approved safekeeping equipment whenever it is not in use or under direct supervision of authorized employees. Custodians shall follow procedures which insure that unauthorized persons do nor gain access to classified defense information or material by sight or sound, and classified information shall not be discussed with or in the presence of unauthorized persons.

(f) *Telephone Conversations*: Defense information classified in the three categories under the provisions of this order shall not be revealed in telephone conversations, except as may be authorized under section 8 hereof with respect to the transmission of Secret and Confidential material over certain military communications circuits.

(g) *Loss or Subjection to Compromise*: Any person in the executive branch who has knowledge of the loss or possible subjection to compromise of classified defense information shall promptly report the circumstances to a designated official of his agency, and the latter shall take appropriate action forthwith, including advice to the originating department or agency.

SECTION 7. ACCOUNTABILITY AND DISSEMINATION

Knowledge or possession of classified defense information shall be permitted only to persons whose official duties require such access to the interest of promoting national defense and only if they have been determined to be trustworthy. Proper control of dissemination of classified defense information shall be maintained at all times, including good accountability records of classified defense information documents, and severe limitation on the number of such documents originated as well as the number of copies thereof reproduced. The number of copies of classified defense information documents shall be kept to a minimum to decrease the risk of compromise of the information contained in such documents and the financial burden on the Government in protecting such documents. The following special rules shall be observed in connection with accountability for and dissemination of defense information or material:

(a) *Accountability Procedures:* Heads of departments and agencies shall prescribe such accountability procedures as are necessary to control effectively the dissemination of classified defense information, with particularly severe control on material classified Top Secret under this order. Top Secret Control Officers shall be designated, as required, to receive, maintain accountability registers of, and dispatch Top Secret material.

(b) *Dissemination Outside the Executive Branch:* Classified defense information shall not be disseminated outside the executive branch except under conditions and through channels authorized by the head of the disseminating department or agency, even though the person or agency to which dissemination of such information is proposed to be made may have been solely or partly responsible for its production.

(c) *Information Originating in Another Department or Agency:* Except as otherwise provided by section 102 of the National Security Act of July 26, 1947, c. 343, 61 Stat. 498, as amended, 50 U. S. C. sec. 403, classified defense information originating in another department or agency shall not be disseminated outside the receiving department or agency without the consent of the originating department or agency. Documents and material containing defense information which are classified Top Secret or Secret shall not be reproduced without the consent of the originating department or agency.

SECTION 8. TRANSMISSION

For transmission outside of a department or agency, classified defense material of the three categories originated under the provisions of this order shall be prepared and transmitted as follows:

(a) *Preparation for Transmission:* Such material shall be enclosed in opaque inner and outer covers. The inner cover shall be a sealed wrapper or envelope plainly marked with the assigned classification and address. The outer cover shall be sealed and addressed with no indication of the classification of its contents. A receipt form shall be attached to or enclosed in the inner cover, except that Confidential material shall require a receipt only if the sender deems it necessary. The receipt form shall identify the addressor, addressee, and the document, but shall contain no classified information. It shall be signed by the proper recipient and returned to the sender.

(b) *Transmitting Top Secret Material:* The transmission of Top Secret material shall be effected preferably by direct contact of officials concerned, or, alternatively, by specifically designated personnel, by State Department diplomatic pouch, by a messenger-courier system especially created for that purpose, or by electric means in encrypted form; or in the case of information transmitted by the Federal Bureau of Investigation, such means of transmission may be used as are currently approved by the Director, Federal Bureau of Investigation, unless express reservation to the contrary is made in exceptional cases by the originating agency.

(c) *Transmitting Secret Material:* Secret material shall be transmitted within the continental United States by one of the means established for Top Secret material, by an authorized courier, by United States registered mail, or by protected commercial express, air or surface. Secret material may be transmitted outside the continental limits of the United States by one of the means established for Top Secret material, by commanders or masters of vessels of United States registry, or by United States Post Office registered mail through Army, Navy, or Air Force postal facilities, provided that the material does not at any time pass out of United States Government control and does not pass through a foreign postal system. Secret material may, however, be transmitted between United States Government and/or Canadian Government installations in continental United States, Canada, and Alaska by United States and Canadian registered mail with registered mail receipt. In an emergency, Secret material may also be transmitted over military communications circuits in accordance with regulations promulgated for such purpose by the Secretary of Defense.

(d) *Transmitting Confidential Material:* Confidential defense material shall be transmitted within the United States by one of the means established for higher classifications, by registered mail, or by express or freight under such specific conditions as may be prescribed by the head of the department or agency concerned. Outside the continental United States, Confidential defense material shall be transmitted in the same manner as authorized for higher classifications.

(e) *Within an Agency:* Preparation of classified defense material for transmission, and transmission of it, within a department or agency shall be governed by regulations, issued by the head of the department or agency, insuring a degree of security equivalent to that outlined above for transmission outside a department or agency.

SECTION 9. DISPOSAL AND DESTRUCTION

Documentary record material made or received by a department or agency in connection with transaction of public business and preserved as evidence of the organization, functions, policies, operations, decisions, procedures or other activities of any department or agency of the Government, or because of the informational value of the data contained therein, may be destroyed only in accordance with the act of July 7, 1943, c. 192, 57 Stat. 380, as amended, 44 U. S. C. 366–380. Non-record classified material, consisting of extra copies and duplicates including shorthand notes, preliminary drafts, used carbon paper, and other material of similar temporary nature, may be destroyed, under procedures established by the head of the department or agency which meet the following requirements, as soon as it has served its purpose:

(a) *Methods of Destruction:* Classified defense material shall be destroyed by burning in the presence of an appropriate official or by other methods authorized by the head of an agency provided the resulting destruction is equally complete.

(b) *Records of Destruction:* Appropriate accountability records maintained in the department or agency shall reflect the destruction of classified defense material.

SECTION 10. ORIENTATION AND INSPECTION

To promote the basic purposes of this order, heads of those departments and agencies originating or handling classified defense information shall designate experienced persons to coordinate and supervise the activities applicable to their departments or agencies under this order. Persons so designated shall maintain active training and orientation programs for employees concerned with classified defense information to impress each such employee with his individual responsibility for exercising vigilance and care in complying with the provisions of this order. Such persons shall be authorized on behalf of the heads of the departments and agencies to establish adequate and active inspection programs to the end that the provisions of this order are administered effectively.

SECTION 11. INTERPRETATION OF REGULATIONS BY THE ATTORNEY GENERAL

The Attorney General, upon request of the head of a department or agency or his duly designated representative, shall personnally or through authorized representatives of the Department of Justice render an interpretation of these regulations in connection with any problems arising out of their administration.

SECTION 12. STATUTORY REQUIREMENTS

Nothing in this order shall be construed to authorize the dissemination, handling or transmission of classified information contrary to the provisions of any statute.

SECTION 13. "RESTRICTED DATA" AS DEFINED IN THE ATOMIC ENERGY ACT

Nothing in this order shall supersede any requirements made by or under the Atomic Energy Act of August 1, 1946, as amended. "Restricted Data" as defined by the said act shall be handled, protected, classified, downgraded, and declassified in conformity with the provisions of the Atomic Energy Act of 1946, as amended, and the regulations of the Atomic Energy Commission.

SECTION 14. COMBAT OPERATIONS

The provisions of this order with regard to dissemination, transmission, or safekeeping of classified defense information or material may be so modified in connection with combat or combat-related operations as the Secretary of Defense may by regulations prescribe.

SECTION 15. EXCEPTIONAL CASES

When, in an exceptional case, a person or agency not authorized to classify defense information originates information which is believed to require classification, such person or agency shall protect that information in the manner prescribed by this order for that category of classified defense information into which it is believed to fall, and shall transmit the information forthwith, under appropriate safeguards, to the department, agency, or person having both the authority to classify information and a direct official interest in the information (preferably, that department, agency, or person to which the information would be transmitted in the ordinary course of business), with a request that such department, agency, or person classify the information.

SECTION 16. REVIEW TO INSURE THAT INFORMATION IS NOT IMPROPERLY WITHHELD HEREUNDER

The President shall designate a member of his staff who shall receive, consider, and take action upon, suggestions or complaints from non-Governmental sources relating to the operation of this order.

SECTION 17. REVIEW TO INSURE SAFEGUARDING OF CLASSIFIED DEFENSE INFORMATION

The National Security Council shall conduct a continuing review of the implementation of this order to insure that classified defense information is properly safeguarded, in conformity herewith.

SECTION 18. REVIEW WITHIN DEPARTMENTS AND AGENCIES

The head of each department and agency shall designate a member or members of his staff who shall conduct a continuing review of the implementation of this order within the department or agency concerned to insure that no information is withheld hereunder which the people of the United States have a right to know, and to insure that classified defense information is properly safeguarded in conformity herewith.

SECTION 19. REVOCATION OF EXECUTIVE ORDER NO. 10290

Executive Order No. 10290 of September 24, 1951 is revoked as of the effective date of this order.

SECTION 20. EFFECTIVE DATE

This order shall become effective on December 15, 1953.

DWIGHT D. EISENHOWER.

THE WHITE HOUSE, *November 5, 1953.*

The CHAIRMAN. Proceed, Mr. Niederlehner, if you will.

Mr. NIEDERLEHNER. The standard which is prescribed by the President for us is the national security. The Executive order sets out basically three classifications in descending order of criticality of the information. Top Secret, Secret, and Confidential. It further prescribes the method of classification, the authority to apply the classification, the process of declassification, marking and identification, custody and safekeeping, accountability, and dissemination, including transmission—the manner in which these documents are passed from one authorized agency to another.

The declassification of material is also provided for within the Executive order. And this is one of the serious problems which confronts the Department of Defense at the present time.

We have had a special study performed by a committee which was known as the Coolidge committee, headed by Mr. Charles Coolidge, of Boston. And as a result of his studies a separate division was set up within the Department to study the process of declassification of documents to relieve us of the burden of a tremendous accumulation of material. That division is presently engaged in an effort to simplify the entire declassification process. And if possible establish a system of automatic declassification by cutoff dates, with minimum exceptions.

Until that directive actually goes into effect, the Executive order itself which provides for classification also provides systems of declassification. It encourages automatic changes on the basis of cutoff dates. It provides for systems of review so that the material may from time to time be declassified. It established further conditions; for example, upon removal of certain attachments to documents, there may be declassification; or upon the occurrence of a specific event, after which the material presumably has no further security value.

The difficulty with the present system, I think, is the requirement of the exercise of judgment with respect to the individual piece of

classified material which is in possession of the Government. And when the custodian is busy performing other duties, sometimes he doesn't have time to go back and review the activities of yesterday and attempt to declassify it.

To alleviate this situation, as I say, we are addressing ourselves to a system of automatic declassification on the theory that after the passage of a certain period of time this material will automatically have lost its security significance.

The CHAIRMAN. Do you agree that any new agency established should have access to classified data both ways—the Defense Department with the new agency, and the new agency with the Defense Department?

Mr. NIEDERLEHNER. The standard, Mr. Chairman—I would say this: That if the new agency is going to work in an area—and I understand this is the intention—which will apply the experience and accumulated wisdom of the Atomic Energy Commission on the one hand and the Department of Defense on the other, then in accordance with proper safeguards, it should, of course, be granted access to classified information.

The system of interworking between agencies, I think is quite smooth. There are established standards which apply across the board for clearance and for classification.

And the standard of access is first a clearance of the individual, to determine his own reliability, and secondly a need to know. And I think in the case of an agency which is operating in the field of the new space agency, it certainly will have a need to know all the relevant material already existing in the Government with respect to the activities in which it is going to engage.

Mr. NATCHER. Mr. Feldman.

Mr. FELDMAN. As you know we will have to consider a security provision in the new proposal. That is primarily why we asked you to come here in this connection. And as you just stated, there will be a close working relationship between the Pentagon and a new civilian agency, if and when it is set up.

Now, can you explain briefly what standards are used in connection with determining when materials shall be declassified?

Mr. NIEDERLEHNER. Well, I would say there are no specific standards applied to declassification in and of itself. The process is somewhat the reverse of the classification process. When you find that those considerations which required the original classification no longer obtain, then the material should be declassified.

Would you like to have me read into the record the basis for classification under the present Executive Order 10501 which applies throughout the Government except for the specific provisions of the Atomic Energy Act?

Mr. FELDMAN. Yes.

Mr. NIEDERLEHNER. Section 1, which sets these general standards provides that:

> Official information which requires protection in the interests of national defense shall be limited to three categories of classification which in descending order of importance shall carry one of the following designations: Top Secret, Secret, or Confidential. No other designation shall be used to classify defense information including military information as requiring protection in the interests of national defense except as expressly provided by statute. These categories are defined as follows:

"(a) Top Secret: Except as may be expressly provided by statute, the use of the classification Top Secret shall be authorized by appropriate authority only for defense information or material which requires the highest degree of protection. The Top Secret classification shall be applied only to that information or material the defense aspect of which is paramount, and the unauthorized disclosure of which could result in exceptionally grave damage to the Nation such as leading to a definite break in diplomatic relations affecting the defense of the United States, an armed attack against the United States or its allies, a war, or the compromise of military defense plans or intelligence operations, or scientific or technological developments vital to the national defense."

The next category is "Secret":

Except as may be expressly provided by statute the use of the classification Secret shall be authorized by appropriate authority only for defense information or material the unauthorized disclosure of which could result in serious damage to the Nation, such as by jeopardizing the international relations of the United States, endangering the effectiveness of a program or policy of vital importance to the national defense, or compromising important military or defense plans, scientific or technological developments important to national defense, or information revealing important intelligence operations.

And the third and last category is "Confidential":

Except as may be expressly provided by statute, the use of the classification Confidential shall be authorized by appropriate authority only for defense information or material the unauthorized disclosure of which could be prejudicial to the defense interests of the Nation.

Now, basically the standard is the defense interests of the Nation. There is somewhat of an elaboration in each of these three categories, and the directive which carries out this Executive order within the Department of Defense elaborates these just a bit further by giving examples.

Mr. FELDMAN. The directives, of course, would describe in greater detail what does and what doesn't come under each of these categories. Isn't that right? The directive is a regulation which is promulgated pursuant to the Executive order?

Mr. NIEDERLEHNER. This topic is covered in section IV of the Directive called "Classification categories."

Mr. FELDMAN. Now, in reading from some of the testimony before the Moss committee, particularly some of the testimony of General David, he indicated that his unit might classify 200,000 documents in 1 year and subsequently he would only have time to go over, say, 20,000 of those documents to determine whether they should be declassified in the following year.

Is there some rule or regulation which holds that the person or unit making the classification has to also make the declassification?

Mr. NIEDERLEHNER. There is not a specific requirement for going back to the exact unit or the exact person. This interpretation of the Executive order has had to be considered very carefully in relation to this proposed new procedure for automatic declassification on a time basis.

If you are going to put into effect such an automatic system, of course, it would be totally defeated by reference back to the exact individual or unit which imposed the original classification.

Now, the Executive order provides in section 4 (f) for downgrading—if the recipient of classified material believes it has been classified too highly he may make a request to the reviewing official who may downgrade or declassify the material after obtaining the consent of the appropriate classification authority.

Now, we are applying or proposing to apply this general provision of the Executive order on a very general basis.

We will provide through a Secretary of Defense order for a procedure of automatic declassification, and for the authorization at a fairly low level of delegation for the actual act of declassification, or for the review of the material which is declassified if it does not fall within certain exceptions.

Mr. FELDMAN. Do you have a copy of the Coolidge report available?

Mr. NIEDERLEHNER. I don't have it with me but I can furnish that for the record.

(Following is a summary of the recommendations of the Coolidge committee on classified information. They are taken from the "Department of Defense Implementation of the Recommendations of the Coolidge Committee," which contains the recommendations of the committee, plus their implementation by the Department of Defense:)

Recommendation No 1—Make a determined attack on overclassification, spearheaded by the responsible heads within the Department of Defense, from the Secretary of Defense down.

Recommendation No. 2a.—Supply guides to overcome the generality of classification criteria.

Recommendation No. 2b.—Broaden Recommendation No. 1 by requiring that all superiors reject overclassified material received from subordinates.

Recommendation No. 2c.—Cut down the number who are authorized to classify information as Top Secret and to receive copies of Top Secret papers.

Recommendation No. 2d.—Require that each program or order susceptible of such treatment contain a special paragraph dealing with information security.

Recommendation No. 2e.—Make wholly clear that the classification system is not to be used to protect information not affecting the national security.

Recommendation No. 2f.—Cease attempts to classify information which cannot be held secret.

Recommendation No. 2g—Improve procedures for releasing information as to the existence and general nature of differences of opinion between the several Services to permit authorized representatives to express Service views, without disparaging their sister Services, and without, of course, disclosing information which is classified for reasons other than differences in military concept between the Services

Recommendation No. 2h—Avoid changing scope of classified information to reflect temporary changes in emphasis in our foreign policy.

Recommendation No. 2i.—Establish within the Office of the Secretary of Defense an official who will be responsible for establishing and monitoring an active declassification program.

Recommendation No 3a—Designate one official in the Office of the Secretary of Defense as responsible for seeing that investigations of "leaks" are initiated with utmost promptness on their occurrence and are vigorously pursued.

Recommendation No. 3b.—Within each military department start investigating machinery going instantly upon occurrence of an unauthorized disclosure.

Recommendation No. 3c—Convene courts of inquiry of triservice composition in case of a serious "leak."

Recommendation No 3d.—In case of a "leak" appearing in the press which obviously gravely damages the security of the Nation, and where the source of the "leak" cannot be identified, summons the author to testify in a grand jury investigation in order to discover the source.

Recommendation No 4a—Take prompt and stern disciplinary action when the source of a "leak" is identified.

Recommendation No. 4b—Take prompt and stern disciplinary action when an individual has not accepted a decision reached by the Secretary of Defense or higher authority.

Recommendation No. 4c.—Hold commanders responsible for security derelictions within their commands.

Recommendation No. 5a.—Fix responsibility for protecting administrative matters

Recommendation No. 5b.—Amended Department of Defense Directive 5200.6 to include protection for information relating to advice on official matters and

compel use of "For Official Use Only" stamp on all future documents entitled to protection under that directive.

Recommendation No. 5c.—Initiate a program of indoctrination among all personnel of the Department of Defense to instill a proper regard for safeguarding of all information protected by Department of Defense Directive 5200.6.

Recommendation No. 5d.—Take appropriate and prompt investigative and disciplinary action in cases of unauthorized disclosure of information on these administrative matters.

Recommendation No. 6a.—Take steps to develop a better understanding in certain parts of industry of the hazards to national security resulting from disclosure of certain technical classified information.

Recommendation No. 6b.—Take vigorous steps to stop leaks to trade and technical journals.

Recommendation No. 7.—Exercise care in the publishing of reports of proceedings before congressional committees to eliminate sensitive technical data and classified operational concepts.

Recommendation No. 8a.—Arrange interviews with Department of Defense members through the Office of Public Information, with a representative sitting in if requested.

Recommendation No. 8b.—Release a forceful statement to the press outlining the differences between ordinary peace and the present situation from the point of view of information security.

Recommendation No. 8c.—Give reasons for classification whenever possible when requests for information are denied.

Recommendation No. 9.—Concentrate implementation of these recommendations on the Washington area.

CHARLES A. COOLIDGE, *Chairman.*
Adm. WILLIAM M. FECHTELER, USN (Ret.)
Gen. JOHN E. HULL, USA (Ret.)
Gen. GERALD C. THOMAS, USMC (Ret.)
Lt. Gen. IDWAL H. EDWARDS, USAF (Ret.)

NOVEMBER 8, 1956.

Mr. FELDMAN. Now, you spoke of an automatic declassification by a certain date. What is that date? How does that work precisely in practice? And what is the date, if you can give it to us?

Mr. NIEDERLEHNER. We have under discussion at the present time, a period subsequent to World War II. It is hoped that we will be able to settle upon a period in the total military history, you might say, of the United States in which there was a very abrupt change of technology so that material which existed before that time does not retain, with certain exceptions, significant security aspects.

And what we have in mind at the present time is a date subsequent to World War II.

Mr. FELDMAN. Well, that would still include a great many years. In other words, I want to get to the construction of the matter if I can, from the point of view of a provision in a law which this committee might submit to Congress.

And that is this. I have read in the transcript of testimony before the Moss committee that a situation could exist where 200,000 documents were classified. Because of the lack of time, only 20,000 of those could be reviewed for declassification in subsequent years. As a consequence you have a tremendous accumulation.

So that material which could and should be declassified is never reached because of the piling up of previous years' classification. This continues to a point where it becomes humanly or physically impossible to do the kind of declassification job essential in order to permit the information to become available to the public.

Now, this becomes increasingly important as the result of testimony before this committee by scientists who claim that in order to be

helpful, they must have available as much scientific or technical information as possible.

And certainly, if the material is declassified, it should be made available to them.

Now, using that as a background, could you give us, or could you tell us, what, if anything, the Defense Department is doing to alleviate that situation?

Mr. NIEDERLEHNER. Well, I would like to cover that in two points, Mr Feldman. First, the access to information on the part of scientists or members of the overall industrial community is not blocked or hampered by the fact that the material is classified.

Mr. FELDMAN. Could you tell us why?

Mr. NIEDERLEHNER. Individuals outside of the Government, for example, may be granted access to classified information whenever this is in the interest of national security. And there are three distinct programs within the Department of Defense at the present time to grant such access. First is the program with respect to the actual Government employee, the civil servant; secondly, the military individual who requires access to information; and the third program is the dissemination of information to private industry.

The vast bulk of the scientific and manufacturing work which is performed for the Department of Defense is performed by private industry.

Colonel Rubenstein reminds me that there are approximately 22,000 plants and 3 million people who may be involved in work which is actually classified, so that the material is not generally disseminated to the public, but it is made available to the individual whose performance of duty requires that he know this particular information.

Now, the second portion of your question, I think, relates to the next step which would be actually to declassify the material and put it into the public domain. We have, of course—I have mentioned this problem of the general declassification. And the program does go back, as you say, to 1945, which is a few years ago.

But it is a very practical first step against a vast bulk of accumulation.

Now, the fact that this automatic step is attempted with respect to that vast bulk does not mean that there aren't currently other activities which must be undertaken with respect to not only the accumulations since 1945 but the material which may be receiving a classification today.

Now, the Executive order provides that formal procedures shall be established to provide specific means for prompt review of classified material and its declassification or downgrading in order to preserve the effectiveness and integrity of the classification system and to eliminate accumulation of classified material which no longer requires protection in the defense interests. The big point there is that the effectiveness of the classification system itself depends in large measure upon the reduction of the number of documents which receive the classification.

So that you can maintain a healthy respect for a few documents and really preserve the absolute secrets which require preservation in the national interest.

Now, it goes on to provide the following special rules shall be observed with respect to changes of classification of defense material.

And then there are a number of specific impositions—the automatic changes, the provisions that after a certain date the document is not classified, upon removal of a certain attachment it is not classified, the provision that upon a certain occurrence, upon the launching of a missile or the delivery, shall we say, of a new aircraft for general operational use, certain classification is automatically removed.

In addition to this, as I say, there is the overall requirement throughout the structure for a periodic review.

There are very stringent requirements with respect to the highest classification, top secret, because there is a requirement for a continuous inventory. And there is an automatic incentive, you might say, with respect to the custodian to relieve himself of the burden of this material because of the restrictions upon its use, its storage, and its continued classification. So that the individual, I think, who has the authority to classify really has some countervailing forces upon him. Because when he classifies it, he immediately incurs for himself an administrative burden in handling and disseminating that piece of paper.

And, as soon as he can declassify it, he finds it is much easier for him to deal with it.

Colonel Rubenstein invites my attention to the document which is known as the Armed Forces Industrial Security Regulation.

And in view of the fact that a great volume of this material which relates to technological matters must be constantly in the possession of American industry, there are specific requirements for its classification, its storage, and its use, and its dissemination only to cleared personnel.

There is a specific requirement here for a review and report every 6 months to the contracting officer with respect to the material which the particular plant has in its possession.

I would point out that the plant itself, the private industry, has an administrative burden in dealing with this material, and, therefore, it has an incentive to have it declassified, and to have the material downgraded for ease of handling or for actual disposition or destruction.

Mr. FELDMAN. Now, you spoke of the Coolidge recommendations and the implementation of the Coolidge recommendations with the directive. Has that taken effect as yet?

Mr. NIEDERLEHNER. The principal recommendation in this area related to this vast accumulation of material. And in accordance with this recommendation there was established a separate unit within the Department of Defense, the sole responsibility of which is to seek ways and means of downgrading and declassifying material and having it either disposed of, made available for general dissemination, or as a very minimum to relieve the custodian of this burden of preservation.

There is a division within the Department of Defense under the Assistant Secretary for Public Information which is headed by retired Vice Admiral Hoskins. They are working on the automatic procedure. But also they have a very close working relationship with the military departments in an effort to see that all of these previous devices which are set forth in the Executive order are carried out.

They are confident that they are producing a substantial result even aside from the automatic approach to declassification. And they have been requiring reports on volume of declassification, number of documents declassified, number of documents destroyed, and so forth.

And they are making, as I say, substantial progress outside of the overall approach.

Mr. FELDMAN. Has there been any report from this division on the amount of classification or declassification of progress reports, so to speak?

Mr. NIEDERLEHNER. I think there has been one; yes. Approximately a month ago.

(The above-mentioned report is as follows:)

(The Semiannual Report of the Office of Declassification Policy, July 1–December 31, 1957.)

SEMIANNUAL REPORT OF THE OFFICE OF DECLASSIFICATION POLICY, OASD (PA)
July 1 to December 31, 1957

I. INTRODUCTION

On August 13, 1956, the Secretary of Defense appointed the Committee on Classified Information, with Mr. Charles A. Coolidge as chairman, to study the problem of unauthorized disclosure of classified information, and to suggest means of correcting this threat to national security.

Its report became public November 8, 1956. In addition to a series of proposals for greater protection of properly classified information, the Committee pointed out that overclassification had "reached serious proportions." It recommended a "determined attack" against this practice. Further, it suggested establishment of an office which would be responsible for creating, directing and monitoring an active declassification program. Such a program, the Committee said, should help more fully to carry out declassification provisions of Executive Order 10501 (November 5, 1953), which had "not been working satisfactorily."

Accordingly, on March 22, 1957, Department of Defense Directive 5105.12 authorized the Office of Declassification Policy, and defined its responsibilities within the Office of Assistant Secretary of Defense for Public Affairs.

II. ORGANIZATION OF THE OFFICE

On July 1, 1957, Vice Admiral John M. Hoskins, USN (Retired), was appointed Director of this Office Following assignment of key members to his staff, Admiral Hoskins completed an organization which consisted of the Directorate, an Executive Secretary, a Military Advisory Staff, a Special Assistant for Technical Programs, A Current Programs Division, and a Future Programs Division. (See Exhibit 1 of the Appendix for organization chart.)

By designation of the Assistant Secretary of Defense for Public Affairs, a Declassification Policy Committee was named to include principal military security policy officers in the military departments. This committee, of which Admiral Hoskins is Chairman, consists of Major General Joseph F Carroll, Deputy Inspector General for Security, U. S Air Force; Brigadier General Royal Reynolds, Jr., Director of Plans, Programs and Security in the Office of the Assistant Chief of Staff, Intelligence, U. S Army; and Rear Admiral Vernon L. Lowrance, Deputy Director of Naval Intelligence for Security, U. S Navy. This committee has held a total of thirteen formal meetings to consider problems in connection with the work of the Office.

In addition, Mr. Paul R. Leach, retired Washington newspaperman, was employed as a part time consultant, representing the viewpoint of public information media. As the office penetrates deeper into the area of complex scientific and technical information, it may be advisable to employ a competent scientist as a consultant. At the present time, the Office of Declassification Policy is depending on members of the Office of the Assistant Secretary of Defense (Research and Engineering) and some of the members of their Technical Advisory Panel for informal advice on declassification of scientific data.

III. OVERALL PROBLEM OF ESTABLISHING A DECLASSIFICATION PROGRAM

At one of the early meetings of the Declassification Policy Committee, it was recommended that the Chairman appoint task forces to study the many problems involved, and report to the Committee on courses of action that would lead to the establishment of a coordinated Department-wide program for the downgrading and declassification of classified information.

Further, it was recommended that one phase of the study should be addressed to the possibility of action being taken by the Secretary of Defense to accomplish two things:

A. To declassify by blanket order information contained in classified documents originated prior to some specified date; and

B. To establish a requirement effecting automatic downgrading of information from the higher categories on a basis of passage of time.

In each case, it was suggested that excepted types of documents and information could be designated in the interest of security.

IV. CURRENT ACTION OF THE OFFICE OF DECLASSIFICATION POLICY AND TASK FORCES

To carry out expeditiously the recommendations of the Declassification Policy Committee, the Chairman appointed five interrelated task forces with specific assignments. In addition, members of his staff were directed to undertake studies of various other segments of the overall downgrading and declassification problem. (See Exhibit 2 for Plan of Operation.) The following progress has been made:

Blanket declassification

Five months of detailed discussions and investigations in conjunction with the military departments and other agencies of the Department of Defense have been conducted by Task Force "A". This has led to the preparation of a proposed directive, which, if approved, will cancel the Defense Department's classification on certain documents which were originated prior to January 1, 1946, and downgrade to SECRET most TOP SECRET documents originated prior to that date which are not declassified by the directive. The proposed directive contains certain excepted categories which have been determined at this time to fall within the specified provisions for safeguarding national security of Executive Order 10501.

Assuming passage of time as an acceptable basis for consideration as to whether documents or information need be kept under protection, the Office of Declassification Policy will continue its study and analysis of those excepted categories so as to narrow progressively the areas which now prevent information from being removed from the classification system.

Task Force "A", in addition to holding a total of six formal meetings, has engaged in countless special conferences with members of the various military departments and other agencies.

It should be noted that in all declassification and downgrading processes, competent review on request will be necessary, initially, to ensure that both security and the public interest are observed.

Automatic Downgrading

Task Force "B" is investigating and studying the problems involved in automatic downgrading of information from the higher categories on the basis of the passage of time. Study to date reveals that although Executive Order 10501 provides that where possible a date for automatic declassification be set at the time of classification, this device is not widely used. This is primarily because of reluctance of people charged with classifying authority to attempt to predict the future. An evaluation of the studies made during recent months by Task Force "B" has led to the conclusion that the technique of automatic declassification by date could and should be used much more widely. Consequently, a directive draft is now being prepared to effect automatic downgrading of information from higher categories on the basis of the passage of time. This problem is scheduled for presentation to the Declassification Policy Committee at an early date.

Because of the complexity of the problem, many separate investigations had to be made by individual members of Task Force "B"; hence, only three formal meetings have been held.

Marking of Declassified and Downgraded Papers

Early in July 1957, the Chairman of the Declassification Policy Committee appointed Task Force "C" to make a study of present requirements for marking of downgraded and declassified documents, and to investigate methods which would reduce this burden.

Following an extensive investigation by Task Force "C," its findings were turned over to Task Force "A," engaged in the preparation of the blanket order directive described above. Simple directions for marking were provided in the draft directive, which were considered adequate by the advisers to the Joint Staff of the Joint Chiefs of Staff with whom the draft directive was coordinated.

Task Force "C" held six formal meetings, and, in addition, investigated various kinds of marking devises. On November 17, 1957, the Task Force, having completed its assignment, was discharged.

Classified technical material at universities

A serious declassification problem was brought to the attention of the Office as a result of an exchange of correspondence between Dr. Frederick L. Hovde, President of Purdue University, and Dr. James H. Doolittle, Chairman, Air Force Scientific Advisory Board. This concerns the disposition of document collections pertaining to basic military research projects conducted by the University. On August 8, 1957, the Chairman of the Declassification Policy Committee appointed Task Force "D" to study the problem and to determine the feasibility of improving the policy with respect to classified material in the custody of educational and research institutions.

Task Force "D" examined records available at the Washington level containing valuable information bearing on the problem. Further, it investigated the extent to which the work of the Armed Services Technical Information Agency (ASTIA) represented a source of assistance affecting university records collections, and the nature of the depository library system established at universities by the Atomic Energy Commission.

Through the efforts of Task Force "D," the Purdue University records collection is now receiving declassification review on an experimental basis by the Air Force Office of Scientific Research. It was felt, however, that a substantial portion of these documents might be subject to the proposed January 1, 1946, directive, while the balance will have to be cleared by regular review procedures. It is hoped that the pilot attention given to the Purdue University case will serve to identify any further problems and provide a guide to future action with respect to classified collections in the custody of other educational and research institutions having similar problems.

Further, the Office of Declassification Policy now is evaluating the feasibility of a plan, resulting from investigations of Task Force "D," to sponsor action by other groups in the Office of the Secretary of Defense to establish a university depository library system.

Task Force "D" held a total of four formal meetings and had numerous informal discussions with representatives of the military services, the Office of the Secretary of Defense, the Atomic Energy Commission, and visited the Armed Services Technical Information Agency center at Dayton, Ohio.

Indexing of Classified Material

In order to recommend practical means of assuring the review and appropriate downgrading or declassification of records at the time they are processed for retirement, the Declassification Policy Committee recommended separate study. On September 5, 1957, the Chairman appointed Task Force "E" to study creation of a subject index and/or catalog of classified documents.

To explore fully the problem involved in setting specific requirements for action in this area, Task Force "E" included members of the records management offices of the three military departments. Preliminary investigation by the Task Force established two basic problems in connection with its assignment:

1. To study the present record index systems used by the military services as to: adequacy in document identification for access; provision for accounting and screening of classified documents; and the use which might be adopted for declassification actions.
2. Investigation toward finding some practical means of assuring review for downgrading or declassification of documents at the time they are processed for retirement.

Task Force "E", after detailed investigation, determined that the maintenance of catalogs of individual random declassifications would serve no purpose, and that declassification on a broad category basis by dates or by subject matter could be maintained centrally and published periodically for use by interested parties.

In the course of its work, Task Force "E" uncovered two apparently forgotten books, published at the end of World War II by the National Archives at a cost of $230,000. These books identify the Department of Defense records of World War II, give a brief description of what they contain, where they are located, and in what amounts It was concluded that, although these books did not specifically meet the needs of this office, they did provide ample guides to help in future work of this office. Also, the Task Force determined that a more detailed index would be prohibitive in light of the expense incurred in compiling even such a broad list as that contained in the above-mentioned volumes.

With respect to the second problem, the Task Force concluded that due to the necessary variations in records management procedures required by the differences in missions and organization of the respective military departments, it would not be desirable or practicable to prepare a single overall directive.

General conclusions of Task Force "E" in this respect are: (1) Greater emphasis by the Office of the Secretary of Defense is needed in order to insure not only review of documents for downgrading prior to retirement, but, also, constant review at the office of origin; (2) authority from the Office of the Secretary of Defense is required to relieve offices of origin of the requirement for individual notification of downgrading action at the time of retirement; (3) overall procedures governing all departments should not be established at the level of the Office of the Secretary of Defense, because costs of consolidating the widely different filing and retiring methods could not be justified.

Following the report of Task Force "E," the Declassification Policy Committee recommended, and the Chairman directed, that certain findings and recommendations with respect to automatic downgrading be turned over to the Task Force charged with responsibility in that area.

Task Force "E" held fourteen formal meetings, and visited the National Archives and other depositories to determine the extent of the problems involved.

V. REPORTING REQUIREMENTS

In accordance with Directive No. 5105.12, the Office of Declassification Policy is responsible for monitoring an active downgrading and declassification program. To perform this function, it is necessary to establish reporting requirements in the military departments and other agencies of the Department of Defense in order to assess adequately the status, progress, efficiency, and effectiveness of the program.

Recently, the staff has been testing out various types of reports in order to establish standards that would be realistic and not impose too great a burden on the military departments, yet would provide the office with sufficient data to determine trends and evaluate the effectiveness of the declassification program. A set of reporting standards now is being developed.

VI. DECLASSIFICATION EDUCATION PROGRAM

Staff studies of the problems involving the declassification and downgrading of documents to which security classification had been assigned suggested that there should be a more realistic initial appraisal of the need for protecting defense information in accordance with Executive Order 10501. It was realized that the amount of classified information could be reduced substantially if means could be developed to overcome the inclination, of those charged with classifying authority, to overclassify, or even to classify, when national security would not be impaired.

It appeared obvious that real achievement in this area would depend, to a large extent, on how well informed the classifiers are with respect to precisely what defense information should be protected in accordance with classification guidelines established by Department of Defense Directive No. 5200.1. It was determined that effective emphasis might be achieved throughout the Department, particularly among officers of the military, if greater attention and/or additional courses in classification and the dangers of overclassification were provided in the several Service schools.

A draft of a proposed memorandum to the Secretaries of the three military departments now is undergoing revision. This will request that serious attention be given to developing programs of instruction in classification policy and techniques in the Service schools. It is hoped that such courses of instruction will lead to more realistic classification and less overclassification.

As a result of discussions at several Declassification Policy Committee meetings, the Navy Department already has taken active steps in anticipation of the memorandum by issuing instruction to 6 Service schools and 58 reserve schools, stressing the dangers of overclassification and emphasizing the needs and means for declassification. (See Exhibit 3 for Instruction.)

An article is scheduled for publication in the Navy's quarterly training bulletin, stressing the evils of overclassification. (See Exhibit 4 for copy of article.) The Navy's new security manual, now being printed, has been carefully edited to eliminate any looseness that would precipitate overclassification and to emphasize declassification. This revised edition, for correspondence courses and officer promotion examinations, incorporates instruction and questions on overclassification and declassification.

VII. SPECIAL PROJECTS UNDER JOINT STUDY WITH MP&R

Employing specific talents and particular experience of certain members of the staff, studies of two problem areas in the technical and industrial fields were sponsored by the Office of Declassification Policy. They now are being worked on with the staff of the Office of the Assistant Secretary of Defense (Manpower, Personnel, and Reserve). If these two projects succeed, a policy will follow for uniform phased downgrading and declassification of specific technical subjects. In addition, a substantial dollar savings in the industrial field will result. Outlines of these projects and the progress made to date follows:

A. Phased downgrading and declassification plan

Lack of uniformity in criteria for classifying and declassifying exists throughout the technical fields due primarily to emphasis being placed on physical protection for classified documents and material. If any considerable part of this matter is overclassified, the cost to the Government for guarding, packaging, and shipping is far in excess of what would be required if security considerations were realistically applied.

Early in November 1957, the Office of Security Policy (MP & R) sponsored an ad hoc committee to consider the desirability of adopting the U. S. Navy Bureau of Aeronautics' concept of a classification guide and phased downgrading system. Cognizant security personnel of the military services and a member of this staff served on this committee. After two meetings, it was unanimously agreed that the principle involved appeared sound and would be desirable if it could be applied "across the board." To this end, a working group was set up to develop the concept. The initial meeting of this group was held the first week of December 1957. The group has continued to meet once a week for a three-hour session. Progress has been made in the formulation of criteria and details necessary for a combined system. A member of this staff also is on this working group.

B. Accountability for destruction of contractor-generated confidential material

Industrial companies in the process of manufacturing classified equipment under Department of Defense contracts usually generate thousands, and even sometimes millions, of classified documents, such as inter or intraplant orders and memoranda, partial or complete reproductions of classified drawings and specifications, status or progress reports.

Under the regulations of the May, 1955, Industrial Security Manual, the contractor was required to record the destruction of all Top Secret and Secret information, and only such Confidential information as was furnished by the Government However, under the Manual as revised in September, 1956, paragraphs 8 and 14f require that an appropriate recording of Confidential information destroyed shall be maintained by the contractor for a period of ten years. Under this new requirement, the contractor has three alternatives, as follows:

1. To return millions of Confidential documents to the Government for storage, which would place a tremendous and costly burden on Government storage facilities and personnel;
2. To make the required appropriate record of each document destroyed, which would require about 4.5 man-hours per 1,000 documents, resulting in exceptionally large costs for each contractor, which would ultimately be charged against the cost of those or other contracts; or
3. To retain tons of old and largely useless Confidential files and provide the necessary storage space and safeguards, which, likewise, would have a high cost factor that the contractor would have to charge against contract costs.

However, the definition of what constitutes an appropriate recording for the destruction of contractor-generated Confidential information is subject to wide differences of interpretation. For example, many legal departments of reputable companies interpret an appropriate record to require full accountability. The cost of such accountability of Confidential matter by industry is estimated to be in the order of hundreds of millions of dollars per year, an even greater amount than the cost of retaining these old documents.

The extent of this problem, and its importance to industry and the Government, was brought to the attention of the Office of Declassification Policy by a member of the staff. An informal conference was held with several members of industry to determine if this Office could take any action by means of declassification techniques. It was decided first to enlist the support of the Office of the Assistant Secretary of Defense (MP&R) since the Industrial Security Manual is the responsibility of that Office. A meeting was held with members of the staff

of that Office, with the result that an immediate study of the problem was undertaken.

This Office was notified that new and corrective language is being prepared as an amendment to the Industrial Security Manual, which it is hoped, will eliminate this condition. This Office realizes that this proposal represents one of the most forward steps in our declassification program with respect to industry, and intends to follow its progress to assure a successful conclusion, either in conjunction with MP&R or by declassification means.

VIII. DIRECT AND INDIRECT RESULTS OF OFFICE OF DECLASSIFICATION POLICY ACTIONS

The Director has been greatly encouraged by both the direct and indirect results of the work of his Policy Committee, the five Task Forces and his staff. Although, in recent years, there has been an established policy in the military departments requiring review of classified matter for possible downgrading and/or declassification, there was little evidence of that policy being vigorously pursued, according to the Coolidge Committee report. If the military departments had been able to observe this policy over the last ten or fifteen years, there would not now be the enormous backlog of classified records and files unnecessarily accumulated in the various storage spaces, warehouses and depositories, that report stated.

It is evident at this time that the creation of this Office has stimulated concern throughout the Defense establishment of the dangers of overclassification, the necessity for a more realistic initial appraisal of the need for protecting defense information by classification, and the desirability of effective downgrading and declassification programs so as to avoid the building up of backlogs in the future.

Some of the direct actions on the part of the military departments are listed below:

A. U. S. Army actions

In September, 1957, the Army initiated action to revise its Military Security Manual AR 380–5, which will improve security, the administration of documents, the release of information to the public, and its provisions for declassification.

The two most import revisions which concern the Army's declassification program are:

1. Review for regrading with respect to responsibility. "In order to preserve the effectiveness and integrity of the classification system and to eliminate accumulation of classified material which no longer requires protection in the interests of national defense, every commander will keep under constant review all classified information in his custody or of primary interest to him. He will initiate action toward downgrading or declassifying it as conditions warrant. He also will designate persons (normally Security Control Officers) * * * to be responsible for continuing review and downgrading or declassifying of classified material originated within his headquarters and to act on requests for such review."
2. Downgrading or Declassification. "Top Secret and Secret material originating within the Army Establishment will be regraded Secret and Confidential respectively three years from the date of origin unless the originator or higher authority has: (1) authorized earlier downgrading by establishing a specific date or event for such downgrading, or (2) renewed the original classification by notification to all recipients prior to expiration of three years from the date of origin. Material for which the original classification has been extended by action in accordance with * * * above, will be subject to the same action three years from the date of the extension."

Further, the Army has issued two promotional items concerning downgrading and declassification, which have been distributed to all locations. (See Exhibits 5 and 6.) Exhibit 5 is a security classification guide, which now also is being distributed by the Security Services Division of the Office of the Secretary of Defense. The Navy and the Air Force will be urged, also, to adopt this promotion device through the Declassification Policy Committee.

The Army has taken steps to reduce drastically the number of individuals who are authorized to assign the classification of Top Secret to defense information. A conservative estimate indicated that approximately 1,600 individuals in the Department of the Army previously had authority to originate Top Secret material. Changes now being instituted indicate that the number of individuals will be limited to 46, and they will not have authority to delegate this responsibility.

Likewise, the authority to classify material Secret and Confidential will be curtailed to the maximum extent possible consistent with efficient operations.

Since July 1957, more than 90 news items were released to the public, all of which contained references to data which had to be declassified before the announcements could be made. Also, the various branches of the Army are reviewing over 1,300 reports annually with a view to declassification and ultimate publication in scientific and technical journals.

B. U. S. Navy and Marine Corps actions

The Chief of Naval Operations has circulated a draft of a proposed OP NAV Instruction entitled, "Declassification and Downgrading Program." This instruction grew out of the Navy's anticipation of a reporting requirement which would be forthcoming from the Office of Declassification Policy. The first staffing draft of this instruction was originated on July 25, 1957. The purpose of the instruction, in addition to a request for comments on an attached reporting form, was to emphasize the importance of the downgrading and declassification in the Navy, and to direct effective implementation. Included in this draft instruction are these reasons for the need of an active declassification program:

1. High cost in time, money, and personnel required for controlled handling, secure transmission, executing endless receipts, special security storage equipment, and reoccurring inventories.
2. Jeopardizing careers of personnel from security violations involving improperly classified information.
3. Poor public relations resulting from adverse criticism concerning vast volumes of classified records. Several methods of control of classification are mentioned, such as automatic downgrading or declassification after a given date, or upon a certain event, and controlling original classification. Also, a requirement is proposed for periodic inspections.

Authority to classify material in the Department of the Navy was delegated to approximately 2,890 persons prior to July 8, 1957. With the promulgation of the revised Navy Security Manual, original authority to assign Top Secret classification will specifically designate only 181 persons by title of office. This will result in about 50 persons having original classification authority for approximately 90% of all Top Secret Naval documents. Authority to assign Secret and Confidential classifications will be proportionally reduced.

Since June, 1957, the Navy has released 116 news items to the public which required certain downgrading and declassification action before they could be released. In addition, for use in Naval History, 250 photographs and 50 documents were declassified by the Security Review of the Navy.

Marine Corps actions

The U. S. Marine Corps has instituted an active declassification program under Headquarters Order No. 5511.7, dated 1 November 1957 (See Exhibit 7 for copy of Order), which requires that representatives from each Division and Department report on specific days to the central files for the purpose of review and marking of classified documents.

Since promulgation of this Order, all classified Marine Corps Headquarters' documents which were originated during 1955 have been reviewed with the following results:

Documents processed	2,938
Documents retaining original classification	1,717
Documents downgraded	219
Documents declassified	1,002

A schedule is anticipated to enable review of two past year documents during each coming year until all old records have been processed.

It is interesting to note that of the 1,002 documents which were declassified, there are still 800 which require that recipients of copies be notified. Personnel limitations and time involved in tracing through all the holders has caused the backlog. To overcome this problem, the Marine Corps bulletin now carries a list of declassifications by subject, serial number and recipients.

In addition, specific changes in "Procedures for Reclassification and Declassification" now are being incorporated in the revised version of the Marine Corps Security Manual. (See Exhibit 8 for a copy of these changes.)

C. U. S. Air Force actions

Although the Air Force basic security manual, AFR 205-1, was prepared shortly before the Office of Declassification Policy was established, its provisions with respect to emphasis on downgrading and declassification are still timely and

effective. However, these changes, which bear on the subject, recently have been transmitted to the field units:

1. Specific designation of individuals within the Air Force authorized to assign security classification. It substantially reduces the number of officials authorized to classify Top Secret and Secret.
2. Designation of an official, authorized to classify, as a point of contact for all classification and declassification actions within a headquarters or an office.
3. Outlining of action which is required when classified information is approved for declassification and public release.

The Air Force has carefully reviewed its requirements as to which officials, and how many, should be authorized to assign security classification. With respect to Top Secret and Secret authority, a revision of AFR 205-1, as noted above, has been completed. A previous report from the Air Force indicated that this revision would substantially reduce the number of persons having original classification authority. Indications were that the number would be limited to approximately 50 in the Departmental Headquarters.

During the months of November and December 1957, the Air Force released some 40 news items to the public which were of a technical or semitechnical nature. All of these releases contained information which required certain downgrading and declassification action before they could be released to the public.

VIII. NEW AND FUTURE PROJECTS, THE FEASIBILITY OF WHICH ARE UNDER STUDY BY THIS OFFICE

A. *Future automatic declassifications by specified time*

It became apparent to the staff that there was a need for a type of directive, or directives, that would establish a blanket time limit for future automatic declassification. Two major areas were considered:

1. Automatic declassification of everything, with certain excepted categories, after ten years unless reviewed and redated; and
2. Automatic declassification of all scientific and technical information, with a minimum of excepted categories, after ten years unless reviewed and redated.

Since it was felt that more rapid progress could be made in item 2 above, the staff has vigorously applied itself to the preparation of a draft directive that would meet the objective. At present, this draft is undergoing informal checking with scientific and technical personnel of the Department of Defense. If a favorable reception is given to the proposal, it will be coordinated formally.

B. *Security criteria guide*

A proposal is under consideration, and study begun, for the establishment of an open-ended guide or catalog which would provide a uniform criteria as a reference for all individuals charged with downgrading and declassification responsibilities, and for Public Information Officers, as to what types of information in specific categories are classified or unclassified. The Director is of the opinion that there is room for substantial improvement in the guidance as to what type of information should be classified.

C. *Plan for accelerating the flow of basic and applied military research information to technical colleges*

In December 1957, a plan was proposed for utilizing downgrading and declassification techniques to make available to college scientific and technical ROTC students basic and applied research information developed in connection with military research, development, and production contracts for weapons systems. The Deputy Director has arranged an exploratory conference with the President and faculty of a leading technical school to define areas of interest to the colleges. Some major objectives of the plan are:

1. To provide the United States, in a much shorter period of time, with scientifically and technically trained manpower in greater quantity, and with a much higher level of knowledge of advanced development in science and engineering resulting from research performed on technical military projects.
2. To encourage more technically minded students to enroll in the Reserve Officers Training programs and to stay in the military service for longer periods of time after graduation.
3. To build up a reservoir of scientifically and technically trained personnel for Government, industry, and our colleges, with a much higher level of knowl-

edge in the most modern and advanced scientific techniques than is normally available now from the graduating classes of our technical schools and universities.

4. To develop means for the rapid flow of basic scientific information to the colleges so that the faculty, graduate, and undergraduate students can contribute needed ideas and talents to national defense.

5. To encourage college faculty members to participate more fully in Government basic research programs, and provide the scientific leadership necessary to open up new research horizons and avoid costly scientific blunders.

6. To insure the technical supremacy, and thus the security of this Nation in the years to come, by providing a versatile supply of scientists and engineers capable of developing defensive weapons and the industrial power of this country to such a point as to deter the ambitions of any potential enemy.

J. M. Hoskins,
Vice Admiral, USN (Retired),
Director of Declassification Policy.

NOVEMBER 1957

OFFICE OF THE SECRETARY OF DEFENSE
OFFICE OF ASSISTANT SECRETARY (PUBLIC AFFAIRS)
OFFICE OF DECLASSIFICATION POLICY

OFFICE OF THE DIRECTOR
Director - V/Adm. J. M. Hoskins, USN (Ret'd).
Deputy Director - J. Clifford Johnson.
Secretaries - Genevieve La France.
Sharon Del Vecchio.

Under direction of Assistant Secretary of Defense (Public Affairs) and within the framework of Executive Order 10501, as implemented by Secretary of Defense, originates, directs, and monitors an overall Department of Defense declassification program as prescribed in DOD Directive 5105.12. Director serves as chairman of Declassification Policy Committee.

OFFICE OF EXECUTIVE SECRETARY
Executive Secretary - Curtis G. Meade.
Secretary - Betty Wells.
Clerk-Courier - A/1C George Guidas.

Assists the Director in planning and conducting Committee meetings, organization of subcommittees and work groups. Makes recommendations as to areas to which the Committee should direct its attention. Maintains continued familiarity with & coordinates pending projects. Prepares agenda and briefs Director and other members of Staff concerning matters to be considered by the Committee and suggests possible solutions or appropriate action. Prepares minutes and follows up on decisions and required actions. Responsible for internal administration including communications, records, office supplies & equipment, personnel, budget, etc.

SPECIAL ASS'T FOR TECHNICAL PROGRAMS
Vincent C. Tompkins

Develops and recommends policies, procedures, programs, guidelines and instructions for timely downgrading and declassification of technical information. Maintains liaison with military departments, other executive agencies, and industry. Advises other staff officers, particularly the Director of Current Programs and Director of Future Programs on the effect of proposed policies under their programs and their impact on industry. Confers with scientists, engineers, technicians, and other experts as necessary with regard to these activities.

CURRENT PROGRAMS DIVISION
Director - W. W. Harrison, Jr.
Analyst - George Collins.
Secretary - Mary Pepe.

Develops and recommends new or revised programs, policies and instructions designed to downgrade or declassify information currently under security classification. Designs & establishes reporting systems to measure effectiveness, efficiency and progress of declassification program. Evaluates these programs & prepares appropriate reports for the Director, Ass't. Sec'y. (PA) & other officials.

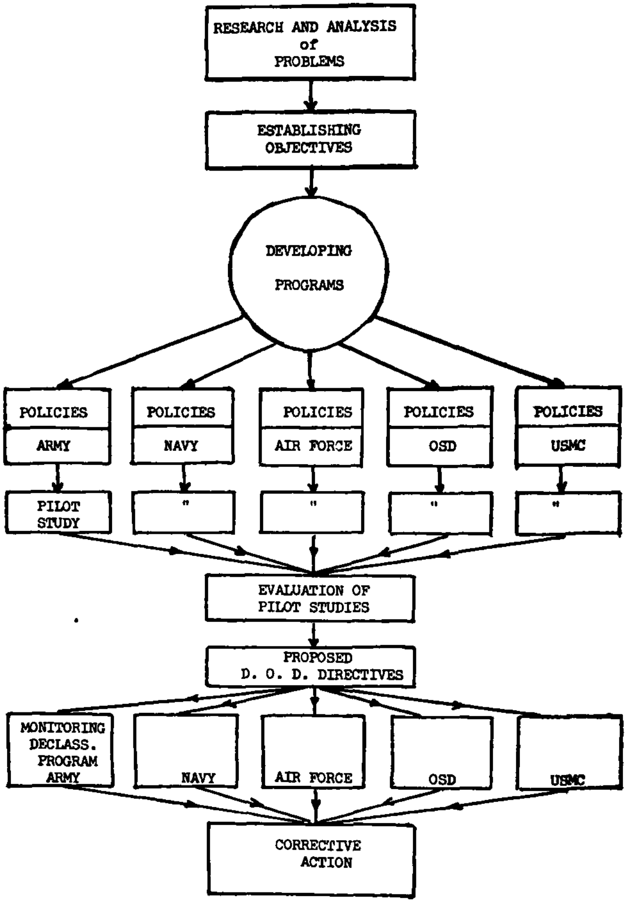
MILITARY ADVISORY STAFF
Col. Richard Hayward, USMC.
Col. John Ferris, USA.
Col. Edward Butler, USAF.
Capt. Gordon Egbert, USN.

Advises Director concerning security matters generally, and classification & declassification specifically, pertaining to each military department. Maintains close liaison with appropriate area of each military department in order to be constantly acquainted with pertinent policies, regulations, & procedures affecting the program of the Office of Declassification Policy.

FUTURE PROGRAMS DIVISION
Director - Hunt Clement, Jr.
Secretary - Ida Mabie.

Responsible for conducting surveys & studies & developing policies & procedures relating to declassification & downgrading of material to be created, as distinguished from current material. Studies patterns relating to long-range problems & is particularly concerned with plans relating to automatic action to prevent further buildup of backlog.

OFFICE OF THE SECRETARY OF DEFENSE
OFFICE OF THE ASSISTANT SECRETARY OF DEFENSE (PUBLIC AFFAIRS)
OFFICE OF DECLASSIFICATION POLICY



DEPARTMENT OF THE NAVY

BUREAU OF NAVAL PERSONNEL

WASHINGTON, D. C.

BUPERS INSTRUCTION 1533.48

From: Chief of Naval Personnel.
To: Distribution list.
Subject: Security of classified matter; information concerning.
Reference: (a) OPNAV INST 5510.1A, U. S. Navy Security Manual for Classified Matter.

1. *Purpose.*—The purpose of this instruction is to insure that training programs conducted by addressees stress the importance of security; including the adverse effects of improper classification.

2. *Background.*—The responsibilities for handling classified information commence early in the life of a newly commissioned officer, especially today when junior officers are called upon to assume duties normally assigned to higher ranks. These responsibilities continue throughout an officer's career in different positions. Among these is the initial responsibility of assigning classifications to correspondence and documents. The lack of experience and fear of reprisal for improper classification generally results in overclassification which not only compounds stowage and handling requirements involving excessive costs in manpower and money, but also detracts from the importance of classification in the minds of all personnel.

3. *Action.*—Addressees are requested to insure that training programs under their cognizance include instruction regarding security of classified matter and that instruction also covers overclassification as set forth in article 0402 of reference (a) and as discussed in paragraph 2 above. It is envisioned that such instruction can be accomplished within the existing framework of course topics. The instruction should be repeated from time to time as appropriate.

J. R. LEEDS
(By direction).

NAVAL TRAINING BULLETIN

February 1958

OVERCLASSIFICATION IS A VIOLATION

LCDR G. B. Tamburello, Training Division, BuPers

Recently VADM J. M. Hoskins, USN (Ret.), was appointed Director of Declassification Policy for the Department of Defense and given the responsibility of declassifying the huge amounts of material held by the Armed Forces in an effort to reduce costs of stowage of such material and to make available to scientists and historians information which is no longer of military value. His task is tremendous—and yet the same problem will be faced continuously unless we learn now how to classify properly and retain that know-how.

First, every one must understand the requirements for each classification as established in the Security Manual. The axiom, "when in doubt, classify," is not a good one. Overclassification compounds stowage and accountability problems; it depreciates the importance of properly classified matter; and it detracts from the importance of classification in the minds of all personnel.

What are some steps to minimize improper classification of matter?

(*a*) Require personnel who initiate correspondence to reread the rules for proper classification.

(*b*) Question critically the assigned classification originated by your office personnel.

(*c*) Question and challenge, if necessary, the classification of material received from other activities.

Matter which is overclassified should be brought to the attention of the originator—just as is done when classified matter is not handled properly. This use of discrepancy reports can create a consciousness of and proper attitude toward classification. The Security Manual, article 0408, states the proper procedures for reclassifying matter.

SECURITY CLASSIFICATION GUIDE

Use the lowest classification consistent with the proper safeguarding of the information. Before you classify, ask yourself—if this information were in unauthorized hands:

—could it result in exceptionally grave damage to the Nation? Then it is Top Secret.

—could it result in serious damage to the Nation? Then it is Secret.

—could it be prejudicial to the defense interests of the Nation? Then it is Confidential.

(See below for definitions of the three categories.)

Classified information—does not have to remain classified. Periodically—review the material you have classified with a view toward downgrading or declassifying it, if appropriate.

Use "automatic downgrading" markings, whenever possible.

Overclassification—

Hampers freedom of information,
Weakens the classification structure,
Overburdens storage facilities,
Delays handling of documents.

CLASSIFICATION CATEGORIES

Information which requires protection in the interests of national defense is limited to three categories of classification:

Top Secret

Information or material, the defense aspect of which is paramount, and the unauthorized disclosure of which could result in exceptionally grave damage to the Nation such as leading to a definite break in diplomatic relations affecting the defense of the United States, an armed attack against the United States or its allies, a war, or the compromise of military or defense plans, or intelligence operations, or scientific or technological developments vital to the national defense.

Secret

Defense information or material the unauthorized disclosure of which could result in serious damage to the Nation, such as by jeopardizing the international relations of the United States endangering the effectiveness of a program or policy of vital importance to the national defense, or compromising important military or defense plans, scientific or technological developments important to national defense, or information revealing important intelligence operations.

Confidential

Defense information or material the unauthorized disclosure of which could be prejudicial to the defense interests of the Nation.

NOTICE

REQUEST THIS FILE BE REVIEWED FOR POSSIBLE REGRADING OF THOSE DOCUMENTS WHICH WERE ORIGINATED BY PERSONNEL OF YOUR DIVISION/OFFICE

NOTE.—If regrading action is considered appropriate, it is requested that action be taken in accordance with paragraph 94, AR 380–5, and recipients of the original document notified in accordance with paragraph 93, AR 380–5. It is further requested that notification of action taken be furnished Administrative Division, Mail and Records Branch, on attached IRS. For additional information contact Ext. 71068.

HEADQUARTERS U. S. MARINE CORPS

WASHINGTON

ADMINISTRATIVE DIVISION

HQO 5511.7
ABQ–glt
1 Nov 1957

HEADQUARTERS ORDER 5511.7

Subject: Declassification or regrading classified material originated within Headquarters United States Marine Corps during the year 1955
Reference: (a) Paragraph 0411 OPNAV INSTN 5510 1A (U. S Navy Security Manual for Classified Matter). (b) HQO 5511.4 of July 5, 1957.

1 *Purpose.*—In order for this headquarters to comply with the provisions of reference (a) in that classified matter will be reviewed for declassification or regrading prior to being forwarded to the Records Retirement Center and to further the declassification and regrading program established by reference (b).

2. *Action.*—Heads of divisions and departments will direct, on the day(s) indicated below, one or more qualified representatives, authorized to review and mark for declassification or regrading, the 1955 documents issued by their respective agency, presently held in the Classified Files Section (room 2109).

Fiscal—November 4.
Inspection—November 5.
Reserve—November 7.
Discipline—8 November.
G–1—November 12.
G–2—November 14.
G–3—November 18, 19, 20.
G–4—December 4, 5, 6.
Aviation—November 21, 22.
Supply—November 15.
Personnel—November 25, 26.
Administrative—December 2.

The Head, Secret and Confidential Files Section, will issue necessary instructions to the Division or Department representative or representatives at the time of arrival as to procedures required in this process and will render assistance in anyway necessary.

3. *Information.*—This order in no way modifies or alters the provisions of reference (b).

4. *Cancellation.*—The provisions of this order are cancelled when all 1955 classified material has been reviewed and for record purposes on February 1, 1958.

By direction of the Commandant.

W K. ENRIGHT,
Colonel, United States Marine Corps,
Director, Administrative Division.

CHANGE IN UNITED STATES MARINE CORPS SECURITY MANUAL

0404 PROCEDURES FOR RECLASSIFICATION AND DECLASSIFICATION

1. A program for reclassification or declassification of classified material originated within Headquarters, U S. Marine Corps will be administered by the Head, Secret and Confidential Files Section on a continuing basis

a Top Secret documents which are to be considered for reclassification or declassification will be transmitted to the Classified Material Control Officer of the cognizant Department, Division or Separate Office in groups of ten or less under cover letter. A new buck tag will be attached to each document and a

rubber stamp indicating action to be taken will be stamped thereon. The officer assigned by the Department, Division or Separate Office to process the classified material and recommend the reclassification or declassification action to be taken will check the appropriate space and sign. Documents will then be returned to the Head, Secret and Confidential Files Section as a complete package with cover letter attached and first endorsement executed. The cognizant Department, Division or Separate Office processing classified material for reclassification or declassification which must be coordinated with other Departments, Divisions or Separate Offices will route the classified material via the Secret and Confidential Files Section. Such routing is to be indicated on the buck tag with code symbols to insure return to the cognizant Department, Division or Separate Office. When material has been processed and returned to the Head, Secret and Confidential Files Section, he will take the necessary action to reclassify or declassify the classified material so recommended for such action and will notify holders of that material. After processing and reclassifying or declassifying action has been taken, the documents will be routed, by endorsement on the cover letter, to the Assistant Chief of Staff, G–3 (Historical).

b. Instructions for the review of Secret and Confidential documents, originated within downgrading or declassification, will be published in Headquarters Marine within Headquarters Marine Corps, for possible downgrading or declassification, will be published in Headquarters Marine Corps directives.

Mr. FELDMAN. Now, you spoke of several programs. Are they in the program stage or are they at a stage where they are in effect and beginning to work or are working?

Mr. NIEDERLEHNER. The several programs which are set forth in the basic Executive order are presently in effect. And those are the programs with respect to which the Hoskins group has already been working with the services and has been obtaining reports on volumes and changes in procedures for marking, changes in responsibilities of individuals, for examples; the level of authority at which downgrading can be undertaken; all of these things are current programs, currently in effect.

And attention is being invited to them by the Hoskins group, in a committee which he has on declassification policy, where the services meet with him in an effort to continually concentrate attention on this program.

The other major step, the attempt at the bulk automatic declassification, is not currently in effect. It has been under study for quite some time. And we hope that very shortly it will be in the form of a positive directive.

It is actually in the final stages at the moment.

Mr. FELDMAN. That is all.

Mr. NATCHER. Mr. Fulton.

Mr. FULTON. I have first the request, Mr. Chairman, to put some material in the record following Professor Cooper's testimony on yesterday as well as the material I am going to request now.

Mr. NATCHER. Without objection it is so ordered.

Mr. FULTON. I would like to put in the record Professor Cooper's precedent-setting lecture delivered in 1951 in Mexico City before the Independent Law Faculty when Professor Cooper was present in Mexico City, as observer in respect to the Legal Committee of the Civil Aviation Organization.

(The above-mentioned paper is on p. 1327.)

Mr. FULTON. Likewise, I would like to have the staff get from the RAND Corp. a summary of the highlights of the RAND Corp.'s bibliography on space which I believe is authoritative.

Might I ask the witness 1 or 2 questions today.

The problem comes up on the setting of a civilian space agency: What will be the relation on classified and secret or confidential material between that civilian Space Agency and the military agencies who are operating on behalf of the Department of Defense; for example, ARPA? What kind of liaison relationship will be there with respect to classified, secret, and confidential material?

Mr. NIEDERLEHNER. I do not know, Mr. Fulton, that a specific formal arrangement need be made.

Mr. FULTON. Could you put that in the record, rather than giving it offhand?

Mr. FELDMAN. As soon as possible, because we want to have the record printed.

Mr. FULTON. Yes. But I think it is better that they be careful about it.

Mr. NIEDERLEHNER. Although I would like to answer in detail, I would like to refer back to my previous statement with respect to overall access to classified information.

I am certain that this agency operating in the field of space will require information both in the atomic-energy field and in the defense field and certainly will be granted access to it.

Mr. FULTON. So that whether it is a completely civilian program or one that is being operated in cooperation with or in behalf of the Department of Defense, there will be access to classified and secret or confidential information?

Mr. NIEDERLEHNER. In accordance with the Executive order, yes, sir; the only standard being the national defense. Whether you go beyond that to a formal type of liaison committee, such as the Military Liaison Committee with the Atomic Energy Commission, which has proved to be very effective, or whether a less formal arrangement is made——

Mr. FULTON. That is part of my question. What kind of implementation would you set up?

And I would rather have your considered views than your offhand views at present.

Mr. NIEDERLEHNER. We will submit those.

Mr. FULTON. As the counsel says, we should submit it—how soon?

Mr. FELDMAN. Yesterday.

Mr. FULTON. Let us finish with this. The problem will come up on research, development, and exploration in outer space as to what kind of a classification there should be for basic scientific material.

There are some of us who want a prompt release of basic scientific material, whether the basic scientific research has been in ARPA or NASA, the new agency.

And likewise we would like to set up some sort of a method of scientific exchange among countries, whether countries of the Free World or all the countries of the world.

Could you—not now, but later—submit a statement as to how you would recommend the handling of basic scientific research material?

Mr. NIEDERLEHNER. Yes, sir.

(The material requested of Mr. Niederlehner follows:)

During the course of the testimony, Mr. Fulton requested that I furnish comments with respect to two matters: (1) Whether or not the relationship between the new Space Agency and the Department of Defense should be through a formal liaison, such as the Military Liaison Committee; and (2) the method of

handling basic scientific material and whether or not it should be protected from general dissemination.

With respect to the first question, the Military Liaison Committee has proved a most effective device for covering matters of common interest between the Atomic Energy Commission and the Department of Defense. However, the formality of this arrangement arose out of the unique relationship of atomic-energy activities to national-defense interests and security matters. We do not believe that a parallel situation exists with respect to the proposed National Aeronautics and Space Agency. We visualize the relationship as similar to that which the military departments have with the National Advisory Committee for Aeronautics which performs functions from which both private and military benefit in the scientific field. I have been advised that liaison has already been established between the Department of Defense and NACA with respect to space matters and is operating very satisfactorily. Accordingly, no formal statutory military liaison committee appears to be necessary.

With respect to the treatment of basic scientific material which may be produced during the course of the work of the new National Aeronautics and Space Agency, it is the position of the Department of Defense that the so-called pure scientific information should be made generally available in the exchange of ideas and information to stimulate overall progress in the basic sciences. It is only when a military application of scientific information develops that the necessity for safeguarding against general dissemination arises (in the interest of avoiding dissemination to potential enemies).

The basis for a special formal system of protection of atomic energy information as "restricted data" was the conviction that this information was the most highly sensitive military information, whereas much of the information developed by the new agency will be of general overall scientific interest. If, as suggested above, the relationship with the Space Agency will be similar to the relationship of the military with NACA, then, in my opinion, it will be practicable to separate the purely scientific aspects of the Agency's work from the military applications. The system for the entire executive branch prescribed by Executive Order 10501 will be adequate, and a formal statutory system of restriction on information will not be necessary.

Two other factors persuade me toward this conclusion. In the first place, the system of restricted data imposes a substantial burden in the interrelationships of agencies, and it should be imposed on the basis of strictest necessity. Secondly, in the interest of overall scientific advance, we should not add to the law an additional system of restriction of information unless this is absolutely necessary.

Mr. NIEDERLEHNER. Could I just point out in passing that the Congress dealt specifically with this problem in the Atomic Energy Act. Whether this was because there was a question as to whether or not all information relating to atomic energy had defense significance the Congress made the decision that it would specifically provide the safeguards for the atomic-energy material whether you could demonstrate a specific military application or not.

Mr. FULTON. I have been interested ever since the early part of last year in setting up some kind of an agency that would be similar to the Atomic Energy Commission. I also favored a joint legislative space committee operated along the lines of the Joint Committee on Atomic Energy.

The point of my question is that we should likewise give our attention, just as we did on atomic energy, to the proper approach of Congress to basic scientific research and scientific knowledge.

This committee has to recommend the policy for the exploration of both astronautics and aeronautics in outer space.

That is all, Mr. Chairman.

Mr. NATCHER. On behalf of our chairman, Mr. McCormack, I want to thank you, Mr. Niederlehner, and also you, Colonel Rubenstein, for the fine statements you have made to our committee and for your appearance at this time.

The committee will stand adjourned until 2 o'clock this afternoon, at which time we will hear Mr. K. T. Keller, former president and board chairman of the Chrysler Corp.

(Whereupon, at 12:16 p. m., the committee recessed, to reconvene at 2 p. m. the same day.)

AFTERNOON SESSION

(The committee reconvened at 2:13 p. m., the Honorable John W. McCormack, chairman of the committee, presiding.)

The CHAIRMAN. The committee will be in order.

The next witness, and I might say the last witness of the public hearing—last but not least—is K. T. Keller, former president and board chairman of the Chrysler Corp., of Detroit, Mich.

We are very glad to have you with us, Mr. Keller.

Mr. KELLER. Thank you, Mr. Congressman.

The CHAIRMAN. And we kept you until the last because we felt that your contributions could be very effective before we go into executive session.

Before recognizing you, I yield to the gentleman from Pennsylvania, Mr. Fulton.

Mr. FULTON. We are glad to note the presence here of the students of the senior class of Allegheny High School near Pittsburgh, Pa. Many of them are interested in the rocket and space exploration field. So here is a class en masse showing their interest in the future and in this select committee's work.

Thank you very much.

The CHAIRMAN. As chairman of the committee I am also glad to note that you are here. You young Americans are the ones that we look to to be the leaders in our Government in the years ahead.

We know that with your loyalty and your faith that you will take the right journey through life and preserve in your day the government and laws which we were fortunate to inherit from past generations of Americans.

I am very glad to see you here and hope you will benefit from being present and seeing democracy in operation in its most effective form—legislation emanating in a committee of Congress, in this case a select committee, on legislation of far-reaching importance in the years that lie ahead, not only for our country but for the world in general.

I again say that I hope you will soak in the atmosphere. I can remember myself when I was about your age, that I never thought I would be in Congress. I never thought I would be majority leader or chairman of this committee. Who knows what life holds in store for any one of us?

And if I might make an observation: I can remember when I was your age, I always said I am going to be the best. And if I wasn't the best, at least by trying to be the best, I was much better than I would have been if I hadn't tried to be the best.

So, I hope you will soak in the atmosphere of a free country where you and I are free men and can be free under the law. And that is the real isthmus between our form of government and the totalitarian form of government that is undertaking to dominate the world where human beings would be mere cogs in the machinery of the state. But here the state or government is the servant of the people.

Mr. Keller, we are very glad to hear from you.

STATEMENT OF K. T. KELLER,[43] FORMER PRESIDENT, CHRYSLER CORP., DETROIT, MICH.

Mr. KELLER. This is on the matter of outer space, space platforms, and satellites, and things of that nature that you are inquiring of me, I presume?

The CHAIRMAN. Yes. Have you a prepared statement?

Mr. KELLER. No, sir.

The CHAIRMAN. You wish to submit to questioning?

Mr. KELLER. Yes, sir.

The CHAIRMAN. Well, suppose we have the chief counsel and director, Mr. Feldman, start asking you questions to lay a foundation.

Mr. KELLER. That is satisfactory.

Mr. FELDMAN. Mr. Keller, you have had a great deal of experience in organizations, in the running of large organizations. Is that right?

Mr. KELLER. I grew up in it, sir.

Mr. FELDMAN. And are you acquainted at all with the legislation before this committee at this time?

Mr. KELLER. Which legislation is that?

Mr. FELDMAN. The President's proposal concerning a space agency.

Mr. KELLER. No, I don't think I have that one. I have the one on reorganization of the Pentagon, which I read several times. But I haven't got the one on this space agency.

The CHAIRMAN. We will keep away, if you don't mind, from the reorganization of the Defense Department.

Mr. FELDMAN. Mr. Keller, you have had a great deal to do with the Defense Department's missile program?

Mr. KELLER. 37 months, sir.

Mr. FELDMAN. Could you tell the committee what your experience was in that connection?

Mr. KELLER. I was requested by Louis Johnson, who was then Secretary of Defense, to come down and see the President. I tried to find out what it was about. But he said "You will find that out when you get here."

He met me at the airport and took me over to the White House. And President Truman outlined to me in general the work that was being done on guided missiles and how important he thought it was to the country, and that he thought there was a great deal of money being spent on it.

He did not know whether we could make any savings. But he was quite sure that it could be moved along faster.

---

And he asked me if I would undertake to do the work. At that time he said "I think we should put our emphasis on defense missiles in particular" and suggested that maybe I would find out that there would be other missiles that should receive attention. I told the President that he was speaking to me of something I knew nothing about, and I could not very well give him an affirmative answer.

But I told him if he would tell me where I could look this matter over I could then tell him whether I thought I could do anything about it.

I did tell him at the time that if I felt that I could do anything about it, I would have to do it the way I thought it had to be done. And he told me that if I came to the conclusion I could be of help to him I could do it any way I wished to do it.

So, I spent some time at the Pentagon Building. And with the help, particularly of the head of the research and development, Mr. Webster, I got a line on what they were attempting to do and the scope of the job. And I found that at that time there were about 4,000 people in the services on guided missile work and about 11,000 in the contractors' places of business.

And I felt at the time that to organize a group of that size would take at least a year and maybe a year and a half, and that the best thing to do would be to work with those people with a small competent staff of our own to try to give it guidance and direction.

And I wish to say that is the basis on which we did the job. And they put me in the organization as a consultant and adviser to anybody that had anything to do with guided missiles.

And we operated on that basis. I selected a small staff of capable men. All of them were in uniform, excepting one man I brought in—an astronomer—on the Atlas job. And we proceeded to go from there.

The complexion of the Defense Department changed considerably. I operated under four Secretaries of Defense. Mr. Johnson went out shortly after I got there. And General Marshall came in. And he was succeeded by Robert Lovett, who was there most of the time.

And I stayed on for a number of months after Secretary Wilson came into the picture.

Now, I do not know what else you would like to know.

Mr. FELDMAN. What was the state of the art when you undertook this?

Mr. KELLER. Well, the state of the art when I undertook it was that we had no missiles of supersonic speed that had their guidance system completed to the place where they could show their capability or prove that the concept was correct.

Mr. FELDMAN. What missiles were developed during the time you were head of this project?

Mr. KELLER. Well, I felt that with my past experience that I have had with development work, that there is one phase of the program that was being overlooked. And that was though our conceptions may be of the very greatest and best, there always comes a time in an engineering, mechanical development where you run into what I choose to call the dirty, stinking work of getting the little problems cleaned up.

And that meant that you had to stabilize your objectives long enough to get hardware and to find out what made malfunctioning in a piece of mechanical apparatus.

For that purpose we picked out three missiles as example missiles to concentrate on and see what we could do to get them into a state of reality. One of the great troubles that you have with the people of the conception department on these thing, is when they run into a little trouble—and particularly if your tests are months a part—they have a lot of time on their hands and they dream up a new one, and always with the belief the new one is going to be better than the one that they had before.

I guess it is somewhat like the next child is going to be the favorite child of the family. But you have still got to raise them. And so we took that approach. And that began to set a little different pattern and a little different approach. And we were able to get very splendid cooperation from the uniformed services, because they sat down and discussed the problems.

Let's take, for instance, the Nike missile, which is the one I think you may be most familiar with. I think the country is most familiar with that one. Our first survey of that job in, I think, November of 1950 indicated that it would have its first full-scale test in the spring of 1955, which seemed to be quite a long time.

But we stayed in conference with the people that were responsible for the development of it long enough and steadily enough to determine that one of the causes of this great delay was the fact that the specifications were changed.

They were pretty well through with their exploratory work, their theoretical exploratory work; so that the Nike would be a very successful missile at the 25 miles and 60,000 feet range; but the specifications or objectives were then moved up on them to 35 miles and 75,000 feet, and that meant a whole new exploration.

Well, in our discussion with the services and with the contractor, we developed the fact that there wasn't any radar completely developed that would detect a target in time to use the 35 miles. There was nothing flying even at 60,000 feet. We had nothing that would shoot an airplane down at anywhere near 25 miles.

So, we came to the conclusion—and it was a mutual one—that if we were to take the original specification of 25 miles and 60,000 feet, that we could get into this hardware stage and begin to learn and get the assurance that comes from doing and accomplishing, and getting a missile, that would be of considerable use, realizing that in this art of defense nothing is permanent.

We even improved the rifle; and any step you take is just one step on the ladder of progress that you make. I told them at the time that in doing that job just as soon as they were ready to explore going 50 miles, that I would be back of them to the limit in getting that job done. Well, the result was that we now have the Nike-Ajax, and had it in operation. It had its full-scale test in early 1952, I think.

When we turned it over for production, they had 7 hits out of 8 shots at White Sands, which we thought was conclusive evidence that the missile would work. And it would be purely a matter of the mechanics of making it and duplicating it. So it would have reliability to be a very effective weapon.

In that time the Nike-Hercules, which has a great deal more range and which range I will not now disclose, has come in and is ready for operational use.

I think they had been working about 4 years on Nike when I came into the picture. I just give that as illustration that you go up this ladder one rung at a time. And I believe there is a third Nike of very important defense possibilities that is now coming along very rapidly.

But I have the very deep conviction that the success we had in proving that minute detail—and, after all, no matter how big a thing is, it has a large collection of detail—proving that detail and learning the art of making it and having the proper concept of the importance of all the little things that go into the job, that formed a platform for both the people that were making it and the using services to understand it and coordinate their work.

And I believe the future Nikes have come along with great saving of time and money by that process. I still belive so.

Does that answer your question?

Mr. FELDMAN. Yes, it does.

In other words, you started from scratch? You had no experience in the missile field?

Mr. KELLER. I didn't know there was a missile around, when Louis Johnson called me.

Mr. FELDMAN. But you did have great experience in running large organizations in the production field?

Mr. KELLER. I have had a lot of experience working with engineers, yes, sir.

Mr. FELDMAN. When you undertook this job, did you assemble some scientists or were they already assembled?

Mr. KELLER. Well, no. I assembled them. I had the, I think, distinct privilege of having the job of making the equipment that separated the isotopes of uranium at Oak Ridge in the absorption process.

We started from scratch on that. And I had a lot of experience with General Nichols, whom I think you know. So, I asked to have General Nichols as my Deputy, which was quite, perhaps, the hardest thing I had to do in connection with the whole field.

But I got him. And then from there we picked up the balance of the organization. I have got here, I think, a paper somewhere. This happens to be the final report that I turned in just before I left the job in 1953.

If I will read this report—this is the only copy I have, and I would like to keep it for my files. I could have it reproduced and send it to you. But maybe if I read it to you—it isn't very long—you will get an answer to a lot of your questions.

Mr. FELDMAN. I would like very much to have it.

Mr. KELLER. August 30, 1950, when the then President requested me to see what I could do to advance the guided-missile program, he agreed to give me wide authority.

Examination of the program showed there were about 4,000 people in the service organizations and 11,000 in contractor and private organizations working on guided missiles. After 90 days of study, including considerable traveling, I felt the best immediate progress and longtime benefit would come from a small organization which

would act as a consultant and adviser to everyone having anything to do with the guided missiles.

This approach worked into a recommendation of a program to be followed on each of the guided missiles.

Our recommendations were submitted to the Secretary of Defense and were approved by him in every case. We received excellent cooperation from the services who handled the administrative work as well as from the research laboratories, engineering organizations, and the contractors engaged in the multitudinous segments of these weapons and their systems.

A small staff was furnished me by the then Secretary of Defense and the three services—Army, Navy, and Air Force. Maj. Gen. K. D. Nichols, United States Army, became my Deputy, and has been with this work continuously since my office was created.

Dr. Robert R. McMath, director of the McMath-Hobard Observatory has acted as a consultant to me since 1951. The other members of this staff were as follows:

And I list here first the Army and the term that they had with me. And I had 3 at one time; sometimes 2.

Colonel White, Colonel Lawless, Colonel Skinner, Colonel Trainer, and Sergeant Krimms. Sergeant Krimms was our security officer.

From the Navy I had Colonel Lumis; Captain Sydes, now Admiral Sydes; Captain Clark, now Admiral Clark; and A. S. Bourne, captain.

From the Air Force I had Brigadier General Robey, Colonel Terhune and Colonel Wetsell.

We started with a staff of 6 military personnel and 2 secretaries. This was shortly increased to 8 and 2 secretaries.

Now the staff consists of 4 full-time and 1 part-time, plus 1 full-time and one part-time secretary. Our Navy berth has been vacant for several months, but the Navy has people who are made available for conferences and inspection trips.

The turnover in personnel is occasioned by the necessity of officers going to other duty in accordance with the established procedures of the services.

In 1950, top priority, as indicated by the Joint Chiefs of Staff, was for defense weapons. The others were still high on the list.

The close examination and study of the whole program, as well as the individual missiles, indicated the wisdom of keeping guided missile study and development as an integral part of the defense and military program.

A reading of the prospectus of any one of these missiles will almost sell it to the using services. The problems of having them perform is a laborious undertaking. Early tests were very disheartening. Aerodynamics and propulsion came along faster than guidance.

Each test that showed failure or even success stimulated new ideas. Failures in tests gave birth to many new conceptions and often new performance possibilities.

Changes in plans and objectives were coming so fast that it was difficult to establish a set of performance characteristics we could stay with long enough to develop a satisfactory weapon.

We early in the first year picked out the Nike, the Terrier, and the Sparrow, all air defense missiles, to work out a program that would bring the overall program along faster and establish just what could be expected of a guided missile.

The Nike-system tests with flying targets was advanced from 1954 to the winter of 1951–52, or about 2 years. This was accomplished by reducing and freezing the performance specifications at the level that it then seemed most likely could be met.

Minimum production setups were authorized on these three missiles so we could get the influence and interests of the production engineer and the master mechanics into the program. It was very evident that hundreds of missiles would have to be tested before we could get the design stabilized and the malfunction chased out of the missile components.

By making missiles for test on the production line, we not only trained the production crews but saved many dollars in the cost of the missiles.

While pushing Nike, Terrier, and Sparrow, we also gave attention to every guided missile the service sponsored. We traveled many miles, held hundreds of meetings with the contractors, laboratory suppliers, and the testing centers and research locations.

We covered each important point of contact at least twice a year. We kept our recommendations current to the condition of development that we considered the missile to be in. The below listing of missiles gives our current thinking on each.

And we have divided these into the three main divisions basic in bringing along any new project and conception to reality. That is to say, research, development, and production.

We further defined each of these divisions as follows: Research is the stage during which theoretical feasibility is proven. Development takes theories coming out of research and brings them along to the point of demonstrating they are practical under controlled conditions. And third, production is the stage in which processes are set up to provide reliable technical equipment to the fighting men and good efficiency and economy.

I think the balance of the memorandum I should read:

Now that Secretary Wilson is building an organization to place the supervision of guided missiles into the administrative department of the Office of Secretary of Defense I have some observations that may be useful to them. I feel strongly that the services should continue to handle the detailed planning and administration of the projects. The coordination of the services should be guided through the Office of the Secretary of Defense.

We always felt that each guided missile, while sponsored by a particular service was nevertheless for all of the services. There are some specific areas of practices that we believe should be overcome in the best interest of the needed rapid progress in missile development. First of all the military should be ready to yield when the insistence on what might be called minor logistic improvements can be shown to complicate and delay development. We must get a workable article first. This will never materialize if we adhere too rigidly to the practice of reaching only for the ultimate in design possibility.

Second, the performance characteristics having been chosen within the reasonable reach of science must be adhered to.

Scientists and engineers worth their salt are always looking ahead toward better things. Control, however must be exerted, so that such changes in specification do not unnecessarily delay achievement of the primary goal.

That is of getting the tactical usable weapon.

The debugging stage in any development is always dirty, exasperating work. It isn't glorious nor glamorous or easy. So an improvement in design is always attractive as a way out of the immediate trouble.

Finally delays in taking remedial action when signs appear that a project is running into trouble must be reduced.

Frequently these troubles are generated by the type of organizational structure engaged in the project. At the very least every project involves a coordinated effort of a military department, a prime contractor and several subcontractors.

The problem of coordinating this effort is like that of running an industry whose parts are scattered all over the country. Project directors of the services must practically live with their projects in the field for only there can the true picture be seen and evaluated.

Medicines needed must be applied promptly rather than allowing situations to deteriorate to the point where the only cure involves surgery.

A greater reliance of the services on the vertical organization for important projects would help.

In conclusion I thoroughly believe that the progress to date warrants everyone being friendly to the missile development program. I further believe that someday they may be our most useful weapons.

Overenthusiasm can also do the program harm. Now is the time for friendly but realistic application of our money and manpower to this work. This is what we have tried to do.

That is the end of the report, sir.

Mr. FELDMAN. Now, Mr. Keller, the committee has before it a proposal which would use the NACA as a building block upon which to build a space agency. Have you had any contact with the NACA as such?

Mr. KELLER. No, sir, I have not.

Mr. FELDMAN. What kind of a man should head up an organization of this kind?

Mr. KELLER. I should think it would have to be a man that has got considerable ability and isn't too overimpressed with the briefings that he gets. I was always taught to buy with my eyes and not with my ears. And you can be led pretty far astray with a pretty plausible briefing.

Mr. FELDMAN. This is a new and far-reaching field, as you know.

Mr. KELLER. Yes, sir.

Mr. FELDMAN. And you in your experience were in pretty much that position when you undertook the program we just went into, that you just described?

Mr. KELLER. Well, sir, I think the nearest example to it, I would say, would be the Atlas, which was purely in the state of discussion at the time. Personally, I felt that we could not afford not to do some work on the Atlas. Yet, on the other hand, I thought it would be exceedingly extravagant to crowd it before we had completely studied the thing from both the standpoint of those who were highly favorable to it and those who felt there might be some trouble with it.

Now, there are some scientists that haven't been too enthusiastic about this shooting the moon. And there are others who have been very enthusiastic about it. And those who have been very enthusiastic about it, since it is sort of a popular subject today and one that seems to get money, have been quite vocal. And I suppose you are going to have quite a time getting those who are not to come out and speak against it.

I am looking, sir, for a report that I had. We took the prospectus on the Atlas job. And that is what I got Dr. McMath in for. I asked him to go through them. It took quite a while. Sir, there was a wheelbarrow load of studies. And after he went through those studies, he came back and said that what these studies say is that if we can do this and this and this, we think the missile will be a success. And then later—and I don't have that letter—at least I can't locate it—he had one of his men from the University of Michigan go into this in greater detail. And he recommended that more time and study be put on the matter of how they were going to get the missile on its

guidance track and how they were going to get reentry of the warhead, feeling that those things could be explored from a laboratory standpoint rather than by building a half-scale model.

And we gave great encouragement to some real straight laboratory work in both guidance and reentry.

I think considerable has been done on that. While it may apparently appear to some people that it delayed the program, I think it has advanced the program, because you know what you are going to have to deal with.

Mr. FEDLDMAN. Well, now, could you indicate to us the kind of a man that should head up an important agency of this kind that is going to be permanent in nature and is going to have this vast undertaking of peacetime development of satellites and space exploration?

Mr. KELLER. I think in the first place he should be a man that isn't interested in promoting any of his own ideas. I think he should be a man that should be perfectly free to buy that which he believes in and not to promote something that he is intrigued with.

Mr. FELDMAN. Well, if a man has had no experience in the building of hardware himself, but has acted merely as head of a service agency, would you say he is qualified to head such an agency?

Mr. KELLER. Well now, you are getting into a pretty difficult area. I don't know how to type people by types. All my life I have selected people by my experience with them and having the deep conviction that the man was suited for the job.

I have watched young men coming along, and when I felt they were particularly good, I usually maneuvered them out of the position they were in into another one, so I could find out whether they were moving with the pack or whether they had the initiative and the ability themselves.

That is a great way to find out. I know the Government cannot go through all of those things. I wouldn't want to be put in the position of trying to pick the man for that job. I think it is a very difficult job. But I do feel this: That if the outer space is important, it should be of greatest importance to our armed services. If it isn't of importance to our armed services, I don't think that the armed services should be deprived of things they need in order to carry on the outer space concept. It is going to take quite a time to determine what the useful things are. But if you don't do some work on it, you will never find out.

Mr. FELDMAN. Are you acquainted with the Jupiter, by the way?

Mr. KELLER. Yes, sir; I know something about the Jupiter.

Mr. FELDMAN. Was that developed at the Ballistic Missiles Arsenal?

Mr. KELLER. That is a ballistics missile. It has had its conception at Redstone under Dr. Werner van Braun, whom I know quite well and respect quite highly.

Mr. FELDMAN. Were any of the same principles in hardware used at Redstone and adapted to Jupiter?

Mr. KELLER. Yes, sir. The principles, in particular.

Mr. FELDMAN. Was the component reliability testing at Redstone directly applicable to Jupiter?

Mr. KELLER. Yes, sir.

Mr. FELDMAN. In the arsenal system of development used by the Army, a missile is developed and the test missiles are made at the arsenal.

Simultaneously, the contractor completes his production engineering work in cooperation with the arsenal, completes his production facility, and it is in production by the time the research and development program is completed. How does this compare in terms of time, money, quantity, and quality with the other system where a contractor produces the test missiles on the final production line and must modify this line and all the missiles he has produced with each change directed by the test firings?

Mr. KELLER. Well, sir, somebody has said it is much harder to make a correct decision than it is to make a decision. And when you get into this testing phase, the missile itself will tell you when you are right and when you are wrong. And your problem is to find out what the missile is telling you.

Now, there are three phases to any missile development. They are propulsion, aerodynamics, and guidance. Propulsion is usually something that is selected from component testing and from the development of fuels.

If you are going to develop a missile, you go over what are the fuels that are available to you. And you know something about the mechanism that is going to be used to handle those fuels; when they are solid, you know considerably about their characteristics and their peculiarities; if they are fluid, you know something about your problems of tankage and pumping; and burning.

Quite often a fuel, particularly a solid fuel, that has been developed for rather small size, doesn't necessarily translate itself into large size and large thrusts without introducing many, many treacherous complications.

So you may have a specific output fuel that has been laboratory tested on a small scale that cannot be immediately put into a large caliber use without bringing in a lot of complications due to making it in large diameters, long lengths, and getting the uniform burning over a much longer period of time.

And that very often bothers the development of a missile.

So that it seems that the history of the thing were that it took about 3 years to develop the thrust and the aerodynamics before you got into your guidance.

Now, there have been built in the last 5 or 6 years some very excellent static testing equipment in this country for testing fuels clear up to full size.

I think the time has to be taken to prove out the burning of this fuel and get its peculiarities and its characteristics and get it stabilized before you begin to commit any guidance to it.

For what I have read of the tests of some of our rockets, a great many of our failures have been due to a failure of propulsion in the first stage. To me one 1,500-mile missile hasn't performed very well. It hasn't completed its first stage of flight. To me that is still just testing propulsion and hasn't anything to do with the complete missile. And the aerodynamics are getting to be better and better known.

There are slight improvements that come along. But we cannot very well commit guidance to a missile that is having trouble with propulsion. It isn't, I think, good to do it; because you complicate the firing, and you put an awful lot of expense into it in putting the guidance in.

So that I think one of the real problems is trying to crowd these things a little too fast sometimes. Sometimes you get a race on, not only between services, but perhaps between contractors that can cost considerable money. And I think the thing has got to be closely handled, yet you have got to be friendly to it. But I think you have got to listen pretty closely to the people who are doing the job.

I always found that you found out more about these problems when you got in the physical presence of them. They have a habit of clearing themselves up when you get in their physical presence and you get to the people who know the intimate detail of what they are working with. These reports that come on up and up, the higher up they get the less what I call germane information is there for you to help you make a decision. That is why we went out in the field most of the time and talked to the people that were doing the work and in the presence of the missiles.

Maybe that is a long, involved statement.

Mr. FELDMAN. It isn't at all.

That is all, Mr. Chairman.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. Mr. Keller, as you know, the bill before the committee, if approved and enacted into law, will provide for research into problems of flight within and outside the earth's atmosphere.

Mr. KELLER. Yes, sir.

Mr. NATCHER. This particular space agency would take over the functions and duties of the NACA. The NACA, Mr. Keller, as you know, is an organization with some 7,600 employees, controlling some $500 million worth of property which is used by the NACA.

Now, as a successful businessman, with your experience in the Government, above all as an outstanding American, Mr. Keller, how do you feel about a program, insofar as outer space research is concerned and our missile program at the present time?

As you well know, at the close of World War II we became very complacent. Our people were much concerned at that time because we were behind. Then Russia developed an excellent jetplane, the MIG–15. They were successfully operating it in Korea. Then we were suddenly startled, as you know, Mr. Keller, to find out that the Soviet Union had placed two satellites in orbit, one over 1,100 pounds.

Now, we have placed three in orbit. And I am just wondering if our people aren't now just a little complacent about it all.

How do you feel, Mr. Keller, about this—the overall program as far as research into outer space?

Our present missile program, should it be a crash program or what should we do?

Mr. KELLER. Well, first let me answer the last part of your question.

My personal opinion of the dither that went through this country with the launching of Sputnik was occasioned by our chagrin. We had been very busy telling the people of the United States how much better we were than the Russians. And I think we were quite chagrined to find they had put a missile into space. If you lick a kid in the alley, you are still his friend unless you go around and tell all the other boys that you licked him and then he is laying to get back at you.

Inasmuch as we are in a geophysical exploration and we are going to give our results to the world for scientific benefit, my personal feeling was—I am glad that the Russians got the missile up and that now maybe we will stop reaching for the moon and use some of the facilities that we have and the equipment we have to put one up which we finally did.

I believe that anything that is on such a high scientific plane as this is never by itself free completely from that which you have done before. The experiences you have had can help and often leads to new things.

And most of this experience is in the services, sir. And I think that regardless of what you do outside of the services, that the services are going to be thinking of practical uses for the defense of this country that they will want to use outer space for.

And I further want to say that I think we have just as fine administrators and men in the services as we have outside of the services. They come from the same kind of homes. They go to our academies, where they get perhaps the best training as Americans. They are sent to other schools beyond that. And I have never failed to find very excellent people.

I think if we did more to put the responsibilities up to the services, that they would handle them better.

The CHAIRMAN. I take it then, you are satisfied?

Mr. KELLER. I am satisfied?

The CHAIRMAN. Yes

Mr. KELLER. I am never satisfied, sir. But there drifted across my desk the other day a pamphlet from Nation's Business. It says: "How to avoid management's 7 deadly sins."

Among them are listed "pride, laziness, anger, unchastity, greed, and gloominess."

I read that article with a great deal of interest, because it is not an article as a basis for criticism of those above you, but rather an article for introspection and self-analysis of your own attitude and character.

But there was a thing in that article at the close that struck me very forcibly. And it put into words better than I ever could the things I have always felt And I have been carrying it in my pocket ever since

I didn't think I would use it here today, but this was said:

> If the feeling of belonging is built up, it can counteract and minimize the tendency of faults to develop. You cannot remake your employees, but you can help develop potentialities. Ideas and execution are seldom found in the same head. But a team operation utilizing strengths to offset weaknesses can minimize shortcomings.

I think that is a very profound thing. I commend the whole article to you. And I believe that in building up any kind of an organization, you have got to have the ideas; you have got to have the administration.

Mr. NATCHER. Mr. Keller, let me ask you this question. As far as our present missile program and our research insofar as outer space are concerned, we have had witnesses appear during the last 2 weeks who have positively stated to this committee that under no circumstances were they in favor of a crash program. And they gave fine reasons why we should not have this type of program.

Are you satisfied, Mr. Keller, with the present rate we are proceeding at?

Should we have a crash program?

Mr. KELLER. I think we are trying to proceed too fast, sir.

Mr. NATCHER. That was the question I had in mind.

Mr. KELLER. I think we have tried to put missiles or satellites into orbit with propulsion foundations that haven't proven themselves.

Mr. NATCHER. As far as our missile program generally is concerned, you believe that we have attempted to proceed too fast, probably based upon what the Soviet Union is doing?

Mr. KELLER. I think we have gotten into the spirit, we might say, of envy. And I think that is a pretty bad thing to get in anybody's mind.

The CHAIRMAN. Does that include the intercontinental ballistics missile?

Mr. KELLER. I think that—well, we haven't fired any intercontinental ballistics missiles——

The CHAIRMAN. I say, in answer to this question.

Mr. KELLER. We are going too fast—yes; we are going too fast in our getting—in our effort to get our bugs cleaned up. I don't think you should have practically 4 succeeding tests of 1 missile in which its propulsion fails.

Mr. NATCHER. Let me ask you this. As far as research into outer space is concerned, do you believe that we should proceed at a more rapid rate, keeping in mind the future of satellites, what they might do, and so forth, and the uses for which they might be made? Are we proceeding fast enough in this particular program?

Mr. KELLER. I don't think so, but you have got to have the ability to lift it up there, to put it into orbit.

And we are putting it up with equipment which we had, which we had under development, some of it more completely developed than the rest, but some of it is still in trouble.

Now, without naming it, your best one today has just recently run into some ball-bearing trouble. And I think that the testing should be held up until static testing has proven that that ball-bearing trouble has been completely licked before you go to work and fire away a million-dollar gadget and a lot of fuel.

Mr. NATCHER. Mr. Keller, I want to thank you for your appearance before our committee.

Thank you, Mr. Chairman.

The CHAIRMAN. Mr. O'Brien.

Mr. O'BRIEN. I agree you should not rush into anything just to accomplish anything spectacular; that we should move cautiously.

But isn't it an admitted fact that the Russians are substantially ahead of us in the propulsion field?

It took 250,000- or 350,000-pound thrusts to get Sputnik up there. The best we have done is between 40,000 and 83,000.

Mr. KELLER. No, we have much more than that, sir. I think the Redstone motor is in the nature of 140.

Mr. FELDMAN. No; 83,000. The Jupiter is 83,000 and the Vanguard is 40,000.

Mr. KELLER. I thought the North American motor was in the nature of 125,000 and specific fuels had brought it up some.

Mr. KEATING. That is what I thought.

Mr. FELDMAN. 83,000 for the Jupiter.

Mr. KELLER. But the information seems to be quite current that the Russians have motors of larger thrust than we have.

Mr. O'BRIEN. That would hardly be a spectacular achievement. That would be a very substantial achievement which could have rather sinister implications unless we catch up in that field.

Mr. KELLER. I think they have been trying to accomplish that by multiple installations.

Mr. O'BRIEN. That I don't know.

Mr. KELLER. Yes, I think so. Of course, when you get multiple installations that is like getting every man on the team to pull his oar with the same strength.

Mr. O'BRIEN. I am perfectly willing to concede that if we put the same emphasis into this field and the same amount of our energy and wealth that we probably would be there, too.

Mr. KELLER. I think that our objectives have been entirely different, sir. I think our objectives have not been to be spectacular in front of the world. I think our objectives have been very realistic. I would be against developing a higher thrust motor just for the sake of outdoing the Russians and putting up a bigger satellite, sir.

The CHAIRMAN. Of course, nobody proposes that. There has been no evidence of such a proposal just for that purpose.

Mr. KELLER. I don't know of any. But I am saying that would be my position. I think that anything that we want to use in connection with our defense activities can be applied to satellite work. It is perfectly all right to do it.

I think we would be lax if we didn't explore satellite stuff when we have hardware and equipment that we can accomplish something with. But I wouldn't create it just for the sake of getting a satellite up.

Mr. O'BRIEN. Thank you, Mr. Chairman.

The CHAIRMAN. But you would, if the satellite would produce information of value to us from a military angle, or for other purposes.

Mr. KELLER. Yes. We can—we don't know what that information is going to be or just how it is going to work. And I am wondering if there isn't some way to prove out the effectiveness of the collection and transmitting of the information without necessarily putting it in a satellite.

Mr. FELDMAN. The scientists seem to feel, of course, that it can't be done nearly as well any other way except that way.

Mr. KELLER. There are certain things I imagine thay can not do anyway except that way. But, we have also got an immediate problem ahead of us. But scientists—and I don't blame them for it—they work at their trade—their business is to advance science, and it is natural they should and if they can get the money I don't blame them for asking for it.

And if I was a scientist, and I wanted to make some exploration and could get the money for it, I would go after it. But we have got to determine here—what we have to determine is somewhat where we put our money, too, you see. Are we going to put it in defense, or are we going to put it in scientific exploration?

When they talk about the condition of the world, Russia vis-a-vis the United States, in one breath you think they (the Russians) are breathing down our neck and they are going to be over here tomorrow,

and I am quite sure no satellite is going to be ready in the next 10 years with conclusive ability to protect us—I think we have to weigh that.

The CHAIRMAN. What about a continental ballistics missile? According to the testimony we have, they are a year and a half or 2 years in advance of us in that field. Don't you think that is a matter of great importance for our country?

Mr. KELLER. Yes, I do, but I think the most wonderful thing that could happen to the world is if you drove a stake in the South Pole and let everybody take a shot at it and see how close they come to it.

The CHAIRMAN. You can do that, of course. We all have theories. We have just got to get back to the practical world again.

Do you sit there with a feeling of security in the knowledge that the Soviet Union, according to the best evidence publicly available—not classified—is a year and a half to two years ahead of us in the field of intercontinental ballistics missiles?

Mr. KELLER. No, I don't feel that way, sir.

The CHAIRMAN. I am not talking about satellites, I am talking about intercontinental ballistics missiles.

Mr. KELLER. I am talking about what we call roughly the 5,000-mile missile.

The CHAIRMAN. The evidence we have is that the propulsion power, the thrust, to send an 1,100-pound Soviet satellite into the air is sufficient propulsion to hurl an intercontinental ballistics missile 5,000 or 5,500 miles.

Mr. KELLER. With what payload?

The CHAIRMAN. Well, the evidence is they can do it. The question is whether it is perfected. That is the question. The reentry and other factors are also involved.

Mr. KELLER. And terminal accuracy.

The CHAIRMAN. Exploration has to be done to determine what bugs exist. It could be improved upon.

Mr. KELLER. Yes, sir.

The CHAIRMAN. They tell me—I don't know how true it is—you know more about that than I do—that the most difficult task is to overcome the propulsion difficulties. After that they can overcome difficulties——

Mr. KELLER. Well, they are the most difficult as long as you have them. But I have also found after they have been licked sometimes those guidance difficulties become very important.

The CHAIRMAN. That is true. But you can't get to the guidance unless you overcome the propulsion.

Mr. KELLER. I tried to bring that out. That is the first thing you have got to develop.

We are not developing, that I know of, any higher specific thrust engines than we now have so far as physical size is concerned. If there is, I do not know anything about it. There may be. But there is no question but that the Russians did put up a sputnik of considerable weight. And I think our scientists can very easily figure the amount of thrust they had to have to do it.

And I do not think that our boys have figured out just how they can make that combination now with existing hardware at this time. Whether they can do it by more multiplication of engines is another thing.

I think that is a matter of time. But I do not think that you can consider this matter of thrust without also considering the tremendous progress that has been made in the warhead of destruction.

For instance, in 1951 we laid down the Redstone missile, because the only bomb that we had at that time proven that would be worth committing to a missile so far as its terminal accuracy was concerned would weigh in the nature of 6,000 pounds.

Well, the work that the Atomic Energy Commission has done in reducing the size and weight and the effective area of destruction its bombs have has been so phenomenal that it has opened up a whole new field of possibilities. Because the lighter your load, the more distance you can cover. And I think that the Atomic Energy Commission should be given a great deal of credit for making our intercontinental ballistics missile possible.

The CHAIRMAN. Well, is it possible?

Mr. KELLER. Yes, I think it is possible.

The CHAIRMAN. I mean, have we perfected it? Of course, it is possible. But we are a year and a half or two years behind the Soviets.

Mr. KELLER. I don't know. I think it has been in the papers that the Army flew one for over 3,000 miles and recovered its warhead. And they did that pretty near a year ago. And I think that tells you quite a bit, doesn't it?

The CHAIRMAN. Well, I would rather get your testimony as to whether you are satisfied with the progress made.

Mr. KELLER. I am never satisfied.

But I want to say this. I think we have made very significant progress. And I am confident that our intercontinental ballistics missiles will be operating and operating successfully.

I cannot put a time limit on it.

The CHAIRMAN. Well, of course, we all agree with you on that. But I would like to have it operating successfully at least before, or not later than, the Soviets operate successfully. Wouldn't you?

Mr. KELLER. Well, the only thing you have told me is——

The CHAIRMAN. Well, wouldn't you?

Mr. KELLER. Why, certainly.

But the only thing that I know about the Soviets is that they have enough thrust to put a sputnik of large size into orbit, larger than we have put into orbit.

The CHAIRMAN. And you attach no significance to that fact?

Mr. KELLER. The only significance I attach to that is that the Russians have developed rockets with more thrust than we have.

The CHAIRMAN. Well, what results might flow from that?

Mr. KELLER. The result that might flow from that is that we do not know how many they have fired. They have put up two. We don't know what their guidance is.

The CHAIRMAN. I mean in terms of other things—intercontinental ballistic missiles—does that have any meaning to you?

Mr. KELLER Well, you still have to have guidance on them.

The CHAIRMAN. I know. But in terms of propulsion of intercontinental ballistics missiles.

We all understand there is a guidance problem and a reentry problem. We are pretty well educated in that.

Mr. KELLER. I know you are.

The CHAIRMAN. But if a nation is a year and a half ahead of another nation, it is reasonable to assume that unless some acceleration is made by the second nation, that the first nation is going to perfect those things before the second nation. Isn't that reasonable to assume?

Mr. KELLER. You can assume those things; yes.

The CHAIRMAN. Certainly.

And in connection with that, they are ahead of us in the intermediate field. You know that, don't you?

Mr. KELLER. No; I didn't.

The CHAIRMAN. Well, if they perfect the intercontinental ballistics missile before we do and at the same time perfect a pretty good defense against our intercontinental bombers, which is our main deterrent? I don't like the word "deterrent." I am not for this idea that we won't attack under any conditions. I think the law of necessity might sometimes compel us to do so.

But we are tied up with that, anyway, in national policy. And if they perfect the intercontinental ballistics missile to the point where it is 85 or 90 percent accurate, that is pretty good accuracy. If, at the same time, they perfect a good defense against our intercontinental bombers, then our deterrent or retaliatory power is pretty well nullified; isn't it?

Now, don't those things happen?

Mr. KELLER. Well, this is the great difficulty I have. All the things are put up on "if's" and assumptions. And most of my life has been trying to give weight to those "if's" and assumptions.

I cannot take all of those "if's" as realities. However, your assumptions are justified and I think this matter of thrust is of great importance to our country.

The CHAIRMAN. Well, we have had testimony from the military, and we have had evidence from others. And those things are not beyond the realm of reasonable probability.

Mr. KELLER. I cannot help what others think, sir. I think for myself. But I have had these pressure things put on me, too, when I was running this guided missiles thing, you see.

But I didn't always buy them. Now, there is a great deal going on in our missiles field. I've seen test stands able to handle much more thrust of static firing of propulsion units. I am not familiar with the programs or progress of larger thrust rockets. And you know we might even get something that will intercept their ballistics missiles.

The CHAIRMAN. That is true.

Mr. KELLER. And I would not wash out the Snark. I can understand that you say, "Well, it is really not a Derby horse."

The CHAIRMAN. Well, how fast does Snark go?

Mr. KELLER. It is subsonic; about the speed of sound.

Mr. FULTON. 0.9 of sound.

It is about 10 percent below the speed of sound; isn't it?

Mr. KELLER. I think the Rascal can be a pretty effective missile, too.

The CHAIRMAN. What is the speed of the Snark?

Mr. KELLER. Mach 0.9.

Mr. FELDMAN. This one goes about 20 times as fast?

Mr. KELLER. Yes; sure.

The CHAIRMAN. How many miles an hour does Snark go?

Mr. KELLER. Mach 0.9 speed of sound.

The CHAIRMAN. How about miles per hour?

Mr. KELLER. That depends on our altitude.

Mr. FELDMAN. 650 miles?

Mr. KELLER. Say 650; yes.

The CHAIRMAN. Do you think that is an effective weapon?

Mr. KELLER. I think it can be.

The CHAIRMAN. Do you think it is the answer?

Mr. KELLER. I think we would be silly to stop there.

The CHAIRMAN. Do you think——

Mr. KELLER. But I wouldn't wash it out.

The CHAIRMAN. I am not talking about washing it out. I don't say it doesn't belong in the arsenal. But I am talking about intercontinental ballistics missiles.

If the Soviets perfect one that can go several thousand miles an hour——

Mr. KELLER. I don't think our ability to make war and win war should be based completely on the enemy's weapons. I think we should give a good bit of weight to our own.

The CHAIRMAN. I agree with you on that. On the other hand, however——

Mr. KELLER. From the psychological standpoint, though——

The CHAIRMAN. Permit me to finish.

I said I agree with you on that. But there is the law of relativity. We can be strong militarily as against Liberia, let us say, but we might be weak against some other particular nation in some respects, important respects; wouldn't we?

Mr. KELLER. I will answer it this way: If we want to make a big impression on the rest of the world, I would sooner have the thrust that the Russians have than to have them have it.

I think that is what you are getting at.

The CHAIRMAN. I will let you know what I am getting at. I believe that if we are going to err, we had better err on the side of strength and not on the side of weakness.

We had better err on the side of security and not uncertainty and insecurity.

Mr. KELLER. I wouldn't disagree with that.

The CHAIRMAN. We wouldn't have any business or anything else if we didn't have the country we have.

And, above all, we have got to preserve our form of government. That is the first thing. And when I hear people talking about coupling this and that, I sometimes wonder just what they mean.

The important thing, after all, is not to waste money. But, on the other hand, if we are going to err, we had better err on the side of progress and strength.

Mr. KELLER. I would not disagree with you one iota on that. But just having somebody make a statement that they are going to do something doesn't mean they are going to do it.

The CHAIRMAN. That is true.

Mr. KELLER. And there is a time when decisions have to be made to go forward and I think this time is here.

The CHAIRMAN. Well, that is why Mr. Feldman asked you the type of man you felt should head up this administration.

Mr. KELLER. Yes.

The CHAIRMAN. I would like, when you edit your remarks, for you to go into it more thoroughly, because you have given some partial answers. I think you might want to elaborate on that.

Mr. KELLER. I think I wouldn't do it with one man.

The CHAIRMAN. Are there any further questions?

Mr. O'Brien.

Mr. O'BRIEN. I would like to explore this a little further.

I think we are all agreed that we do not want to pour tremendous amounts of money into spectaculars.

Mr. KELLER. I agree on that.

Mr. O'BRIEN. I have no desire to send a man to the moon, just to say we did it and the Russians didn't. But isn't it a fact that their concentration on these spectaculars, as we might call it, has outmoded many of the weapons and things upon which we have spent billions and billions of dollars? Isn't it a fact that unless we press forward into the spectacular field, if you wish, that we may very well find that what we are doing now is outmoded tomorrow?

We have got to leapfrog in this field.

Mr. KELLER. I think that has been the history of arms. They have been outmoded. As we have gone along, they have been outmoded.

But, you know, after Hiroshima, we had the feeling there would never be another war. But we forgot that the thing had to be delivered.

The CHAIRMAN. Forgot what?

Mr. KELLER. We forgot that the bomb had to be delivered. And we did wake up to it, though, and went to work on it.

And I think that our services are going to whip this problem and do a spectacular job of it.

I cannot give you the timetable. But I do believe that appointing heads and pressuring this thing around isn't going to do the work.

The work is going to be done down on the hard-work bench. And I am more interested in the people down on the hard-work bench that are doing this job than I am in the guy that is supposed to be heading it up.

The CHAIRMAN. Well, they can't do it unless top management is capable of making the right decision and does make it.

Mr. KELLER. You don't want him alone. You want to surround him with the best advice that you can get and the most practical approach. And I think that you will find a great deal of that; and most of it is in the uniformed services. Because these are people who are going to have to go out and fight these battles. These civilian heads are not going to fight them.

Those uniformed servicemen are interested in their tools. They are perhaps more interested in their tools than anybody else.

The CHAIRMAN. Nobody will argue with you on that, Mr. Keller.

Mr. KELLER. I feel they have the capability.

The CHAIRMAN. But you will admit that in our top management in the military in the past, not so much today, there has been a lack of coordination.

Mr. KELLER. I am awfully glad to hear you say that, coordination, because I think the best thing to be done for the services is to wipe out this word "unification."

There are so many facets to military work that unification and the policy guy who heads the outfit is not necessarily going to make the right decision every time.

It is a matter of how you are going to get coordination between the services because even in each one of the branches you have just as many things to coordinate as you have between the services.

I think the whole heart of this thing goes right back to that statement, how to have them feel that they belong. I feel they are human beings just the same as the rest of us and if you give them somebody to make their decisions for them so they are going to avoid making them, they are going to pass it on to him. If he makes a bad one, it is his fault.

I think if these military people were handled from the standpoint of "We want coordination from you," and you put it on their back, they have the capability of measuring up to it and doing it.

The CHAIRMAN. Are you through, Mr. O'Brien.

Mr. O'BRIEN. Yes.

The CHAIRMAN. Mr. Fulton.

Mr. FULTON. I reserve my time at this point, and first yield as a courtesy to the gentleman from New York, Mr. Keating, in order to alternate the order of questioning on this side.

The CHAIRMAN. Mr. Keating.

Mr. KEATING. I have one line of inquiry, Mr. Keller.

I want to read you a very important sentence from this proposed bill which seems to be the subject of great controversy, both as to what it means and as to what the result means:

> The Congress further declares that such activities—

meaning space activities—

> should be directed by a civilian agency exercising control over aeronautical and space research sponsored by the United States except insofar as such activities may be peculiar to, or primarily associated with, weapons systems or military operations, in which case the Agency may act, in cooperation with or on behalf of the Department of Defense.

Now, the assertion is being widely made in some quarters that this bill is not a bill to place the space exploration in the hands of a civilian agency at all, but is one which indicates that this whole project will be under the sponsorship of Defense.

Now, my own feeling is that if we need to make any changes at all, we need to strengthen the Department of Defense end of it. I favor the civilian agency, but I think that this criticism is ill founded and that the Department of Defense should have greater authority than they have under the terms of this bill.

Now, let me ask you this: So far as you know, all of the space exploration to date has been handled by the military. Is that not right?

Mr. KELLER No, I don't believe so. Isn't Dr. Porter in charge of it?

Mr. KEATING. I mean by the Department of Defense.

Mr. KELLER. Yes.

Mr. KEATING. Both military and civilian in the Department of Defense.

Now, No. 1, you favor the creation of a civilian agency?

Mr. KELLER. You know, it is very hard for me to figure out how words will do a job. And I do not know how to tell you how to set up a civilian agency that will give the military what they need.

Mr. KEATING. You gave one answer to a question which I think I caught correctly, and, if I did, I think we should pursue that.

I believe you said you would not put this under one man. Is that right?

Mr. KELLER. That is right.

Mr. KEATING. Whom would you put it under?

Mr. KELLER. I would form a little board for this thing, and I would form them on the basis——

Mr. FELDMAN. How many?

Mr. KELLER. At least three. I would put them on the basis that they had nothing else to do but that.

Mr. KEATING. Three full-time men?

Mr. KELLER. Three full-time men; and I would take two of them out of the services.

Mr. KEATING. You would have a 3-man board with 2 out of the services?

Mr. KELLER. Yes, sir.

Mr. KEATING. That would rather destroy the character of this as a civilian agency, would it not?

Mr. KELLER. I don't know anything about that. I am not an expert on Government. I am just a mechanic and trying to get things done by the people who do them.

Mr. KEATING. That is not your own concern at all, and we appreciate your being here and you have been very helpful.

Mr. KELLER. My concern is as a citizen.

Mr. KEATING. This bill calls for a single director with an advisory board of 17 members. The director has the authority, but this advisory board is, let us say, advisory-plus. There is a peculiar wrinkle that there are certain things that he must talk to them about before he moves, but he does not have to take their advice. It is a rather unusual arrangement.

Now, would you think that was cumbersome?

Mr. KELLER. I have never been able to do anything with a group of 17. I had a little experience a few years ago.

The mayor of Detroit made me chairman of a committee to lay out what we called the cultural center of the city on a 50-year development and presented me with a committee of 31 people. We had one meeting of the committee and I got them to O. K. an executive group of 4 and we proceeded to lay out the city and after we had it laid out we called the 31 together and we presented a mockup. They liked it and we O. K.'d it. We took it down to the mayor and he liked it and it became part of the city's program.

I think we would be talking yet if we had 31 all doing the study work, because my experience, when you get a committee of that size, is that unless you have something specific for each one of them to do, you get about in the position of the fellow that had the large board of directors and said to one of his directors, "What do you think about this?"

He said, "How do I know what I think until I hear what I say?"

Mr. KEATING. I want to say to you, Mr. Keller, that your suggestion of a three-man board with two from the military is novel. We have not heard that before.

Mr. KELLER. I am glad I came up with something unique.

Mr. KEATING. And we are glad to have you here.

Thank you. That is all, Mr. Chairman.

The CHAIRMAN. Mr. Fulton.

Mr. FULTON. We are glad to have you here. We feel your remarks have been straightforward and you certainly have made your position clear.

Do you think that a board of seven as a commission with, say, three of them from the military services, and with General Doolittle as the chairman, would be a fair type of commission?

Mr. KELLER. I had one experience that I think I should tell you about. I headed up the committee that made the last study on the Maritime Commission, which was composed of a board, I believe, of six, if I remember rightly. When you set these boards up you think they are going to go on a broad policy basis and you are going to get the effect of a lot of brains.

But I am the fellow who headed the committee whose report was taken verbatim by Hoover and resulted in the change in the Maritime Commission.

The reason we arrived at that decision, and we had a group of five on the committee that made the study, was because we found the Commission became an operating commission instead of a policy commission.

They divided the different functions in maritime work among each one and then they would vote.

Of course, they would support the fellow that had the proposition, we will say, on docks and ships and the one that had the one on subsidies. He was the king on those items.

Well, people like to administer. You get a big board and they will split their functions up, you see, and you won't have that detached, independent consideration of all the phases of the thing by the group.

Do I make myself plain.

Mr. FELDMAN. Does a big board lend itself to logrolling?

Mr. KELLER. A big board lends itself to logrolling.

Mr. FELDMAN. I ask that because Dr. Hagen in his testimony before this committee indicated that could happen. He was worried about that fact.

Mr. KELLER. Actually, in the words of Jules Bache, who was a wise old gentleman and happened to be on our board of directors, "The function of a board of directors is to select management; a board is too big to manage and they should select management."

The CHAIRMAN. You were replying, Mr. Keller, to a question about a commission with each man having an operating power or a disivion.

Mr. KELLER. I am in favor of a small group that sets the policies.

Mr. FULTON. That is all. Thank you very much.

The CHAIRMAN. If there are no questions, thank you very much, Mr. Keller. We have enjoyed your appearance before us. We appreciate your testimony.

Mr. KELLER. Thank you.

Mr. NATCHER. Could I make one observation at this point in the record?

I want to thank our counsel and members of the staff. They have done a fine job, a job that has required a lot of patience and a lot of time.

I think Mr. Feldman and the staff should be commended.

Mr. FULTON. I second the motion from the Republican side.

The CHAIRMAN. I think that is the unanimous viewpoint of all the members of the select committee.

We are very fortunate in having Mr. Feldman and the other members of the staff. They have done a remarkable job.

They selected the witnesses. The Chair had nothing to do with it. I delegated authority to them and they have done a remarkable job. I am glad to have the public record show that fact.

Mr. KEATING. I think, Mr. Chairman, if I could be recognized, that the record should also indicate the extreme fairness and courtesy which has attended the operation of the chairman. Every witness, every member of the committee, has been very courteously dealt with and I know all the members feel that way about it.

Mr. FULTON. And so far, in the committee there has been an absence of partisanship.

The CHAIRMAN. I might say that no chairman had better or more dedicated members of the committee, select, standing, or otherwise, than I have had, and I appreciate it very much.

This concludes the public hearings and we will go into executive session next Tuesday at 10 o'clock in the committee's room.

Thank you very much.

The committee now stands adjourned.

(Thereupon, at 3:45 p. m., the public hearing was concluded.)

ASTRONAUTICS AND SPACE EXPLORATION

MONDAY, MAY 12, 1958

HOUSE OF REPRESENTATIVES,
SELECT COMMITTEE ON ASTRONAUTICS
AND SPACE EXPLORATION,
Washington, D. C.

EXECUTIVE SESSION

The committee met at 2 p. m., pursuant to notice, in room B-214, New House Office Building, Hon. Overton Brooks, presiding.

Present: Representatives McCormack (chairman), Brooks, Hays, O'Brien, Metcalf, Natcher, Sisk, Martin, Arends, McDonough, Fulton, Keating and Ford.

Present also: George J. Feldman, director and chief counsel.

Mr. BROOKS. The committee will come to order. The chairman, Mr. McCormack, is over at the Defense Department. He will be in any moment. He is delayed so it was suggested I take the chair temporarily. I know the purpose of the meeting today. Mr. Feldman has reviewed the testimony of the Senate and the House and there are certain things he wants to bring out which will take a little time, so I recognize Mr. Feldman, director and general counsel.

The chairman has gone over the same items that you are going over?

Mr. FELDMAN. Yes; but the chairman thought that we ought to have this meeting. There is an apparent difference between the testimony given previously before this committee and the Senate committee.

I would like to address these questions to Mr Johnson. When you testified before this committee, Mr. Johnson, we named a list of functions such as weather and communications and a million pounds thrust, and so on. We asked whether or not those functions would be military in character or would go to a civilian agency In response to those questions you indicated that the majority of them at least, in your opinion, were military in character and therefore belonged in the military. You also stated that ARPA and NACA were in the process of trying to determine whether the new NASA would have jurisdiction or would have control over those specific functions or that ARPA would have.

Could you tell us whether such a meeting has taken place?

STATEMENT OF HON. ROY JOHNSON, DIRECTOR, ADVANCED RESEARCH PROJECTS AGENCY; ACCOMPANIED BY REAR ADM. JOHN E. CLARK, DEPUTY ASSISTANT TO THE DIRECTOR; DR. HERBERT YORK, CHIEF SCIENTIST; AND ROBERT DECHERT, GENERAL COUNSEL, DEPARTMENT OF DEFENSE

Mr. JOHNSON. Yes, sir; there have been repeated meetings. I have here a document that has not been approved by Secretary McElroy, nor has it been approved formally by the National Advisory

Committee for Aeronautics, although it is now in form ready for the signatures of the two in answer to a request on the part of the President to review the two programs, to come up with a recommendation that was a joint one and to come up with funding recommendations. This document is complete in that we do have a general guide to be used for the identification of the space program.

We have the NACA or Space Agency, if it is created, fiscal year program spelled out over a period of several pages. We have the same positions for Advanced Research Projects Agency. We have the budget proposal for both agencies and a reconciliation of transfer funds.

I must point out that Dr. Dryden has not returned from Europe—may be back now—has not personally approved it but the three members of his staff who were assigned to work with us have approved it. I briefly discussed this with Secretary McElroy this morning. I think he is in agreement with this. I am quite sure, in my own personal opinion, that when the National Advisory Committee for Aeronautics meets on the 15th that they will approve this.

So to answer your question, therefore, this has been accomplished to our satisfaction.

Mr. FELDMAN. This program, I take it, is hypothecated on the assumption that there will be a new NASA?

Mr. JOHNSON. That is right.

Mr. FELDMAN. And only to be effective if and when adopted?

Mr. JOHNSON. That is right, sir.

Mr. FELDMAN. Over what period did these meetings take place?

Mr. JOHNSON. These meetings started promptly after we received the President's letter asking us to engage in this work. I would have to refer to my files to give you an exact date but it was shortly after the President submitted his message to the House of Representatives. This is dated April 2. My recollection would be that these meetings began within the week following April 2.

Mr. FELDMAN. On April 2, about 7 o'clock in the evening, after Congress recessed, we received a copy of the President's legislative proposal. Between that time and the time that you appeared before this committee did you see that bill?

Mr. JOHNSON. We in the Department of Defense had a period allocated to comment on the bill. We in ARPA did comment. So did other parts of the Department of Defense. I believe a consolidated statement was forwarded. I asked Mr. Dechert to appear here today. If you wanted to refer that question to him he could answer it for the Department of Defense.

Mr. FELDMAN. Your answer, incidentally is not responsive to the question. I am not talking about the bill before it was sent up to the House or to Congress. I am talking about the bill between the time it was sent up to Congress, which was 7 o'clock on April 2, and the time you appeared before the committee after it was completed. Did you look at the bill at all?

Mr. JOHNSON. Yes, sir.

Mr. FELDMAN. Did you raise any of the objections that you raised before this committee or make any suggested amendments the like of which you made before this committee when you appeared here, to anybody in the Defense Department or any other agency of the Government concerning the wording of the act, itself?

Mr. JOHNSON. Yes, sir. May I refer to Admiral Clark. We discussed the other day the document we received and commented on within the Department of Defense was language different than now printed.

Admiral CLARK. It was not in this form. I think Mr. Feldman is talking of the time after the bill reached the House.

Mr. FELDMAN. This is what I am getting at. The bill came to the House on April 2, after Congress had recessed. Congress did not reconvene until April 14. You did not testify until sometime after that date.

Mr. JOHNSON. Yes, sir. I understand your question now.

Mr. FELDMAN. Did you look at the bill during that period? Did you examine it?

Mr. JOHNSON. I did, sir.

Mr. FELDMAN. The language we are talking about was in the bill at that time, is that correct?

Mr. JOHNSON. Yes, sir.

Mr. FELDMAN. Did you make any comments or suggestions concerning that language to anyone?

Mr. JOHNSON. I did not recommend specific language within the Department of Defense but I discussed my interpretation and the interpretation of other of my associates which we conveyed to my superiors in the Department of Defense.

Mr. FELDMAN. With whom did you discuss the comments?

Mr. JOHNSON. Secretary Quarles.

Mr. FELDMAN. Specifically, what did you say to him in that connection?

Mr. JOHNSON. The language was too restrictive.

Mr. FELDMAN. Did he agree with you at that time?

Mr. JOHNSON. His interpretation of the language did not agree with mine, no sir

Mr. FELDMAN. At that time?

Mr. JOHNSON At that time.

Mr. McDONOUGH. Mr. Feldman, when you say restrictive you mean too restrictive as to which is military and which is civilian?

Mr. JOHNSON. That is right.

Mr. McDONOUGH. You follow it, George, but I think for the committee's benefit we ought to know what you two fellows are talking about.

Mr. FELDMAN. Did you do anything further about the bill at that time?

Mr. JOHNSON. No, sir. I discussed it with associates in the Department of Defense in an attempt to get every viewpoint on interpretation but I took no positive action other than discussion.

Mr. FELDMAN. Was the testimony you gave before this committee concerning the amendment to the bill of the same general nature of the comment you made to Secretary Quarles at that time?

Mr. JOHNSON. No, sir; I did not recommend any specific language to Secretary Quarles.

Mr. FELDMAN. The language in the exception on page 2 of the bill reads, "Insofar as activities may be peculiar to, or primarily associated with, weapons systems or military operations, in which case the agency may act in cooperation with, or on behalf of, the Department of Defense." Is that the only language in the bill you objected to?

Mr. JOHNSON. That is the only language I objected to.

Mr. FELDMAN. In your testimony before the Johnson committee did you say that if that language was corrected to meet your objections, that would answer your criticism of the bill?

Mr. JOHNSON. After my discussions with Secretary Quarles I did become concerned also with the language having to do with the constitution of the Board, the members from Government and the members from the Department of Defense; it was my intention in the hearings before the Johnson committee to also take exception to that language constituting the Board the number of representatives from the Department of Defense on the Board.

Mr. FELDMAN. In your testimony before this committee you indicated a viewpoint that that language should include more membership of the military on the Board, itself, is that not so?

Mr. JOHNSON. That is my understanding what I said, yes, sir.

Mr. FELDMAN. You did not make an observation of that kind before the Johnson committee, is that right? Or did you?

Mr. JOHNSON. I think there was some reference to that in the testimony. I think they made the statement and I think I did say I agreed in answer to a question.

Mr. FELDMAN. Now, it is our understanding that since you testified before this committee and the corresponding committee in the Senate you have checked the matter further in the Department of Defense, and your views now have official approval. Is that correct?

Mr. JOHNSON. That is correct, sir.

Mr. FELDMAN. In your opinion, is there any need for a civilian agency having a responsibility for research in the problems of flight in outer space?

Mr. JOHNSON. Yes, sir; there is definitely a need for a civilian agency.

Mr. FELDMAN In your testimony before the Senate committee did you not defer this question?

Mr. JOHNSON No, sir; I believe the question I deferred before the Senate committee was whether or not the NACA as now constituted, without any legislation, was adequate to carry on this job. That is the question, as I recall, I deferred an answer to but I repeated in my testimony before the Johnson committee that I was for a civilian agency, that the military could not do this on its own, it could not cover the whole field of science and technology that needed to be explored.

I urged a civilian committee be appointed I think there are 2 or 3 references to it in the testimony

Admiral CLARK. I think, Mr. Feldman, the question that was deferred is one that was worded sort of this way, "Why should there be a civilian agency?" and the idea of deferring was to submit those things which we thought a civilian agency might do, not whether it should be or should not be.

Mr. FELDMAN. Let me read the series of questions:

> Mr. WEISL Now in connection with the development of the ballistic missile for outer space you have had the cooperation of many civilian agencies. There is the radiation laboratory, there is the jet propulsion laboratory at Cal Tech and practically every leading university in the country cooperates with the Defense Department in research and development of the projects in outer space, does it not?
>
> Mr. JOHNSON. Yes, sir. I think this is one of the marvels of this present age. I am astonished at the amount of money voluntarily being spent by private

industry on purely speculation in space technology. We in our industry presentations have listened to 50 or 100 presentations on how to launch spaceships, how to get to Mars, how to get to the moon and so forth.

Mr. WEISL. I am talking about scientific experiments by civilian agencies at the expense of the Government of the United States.

Mr. JOHNSON. Yes, sir, we have had many such agencies.

Mr. WEISL. You had NACA working with you at Government expense?

Mr. JOHNSON. That is right.

Mr. WEISL. Now the reason that I ask this question is this. Why do we need another civilian agency to conduct research in outer space problems when we already have not only 50 research agencies doing this work but in addition have 200 or 300 scientific committees engaged in this work? The question I asked and it is only for the guidance of this committee, is why do we need another agency to do this limited experimenting in outer space when we already have these other agencies engaged in that work?

Mr. JOHNSON. Well, I think NACA has made very fine contributions in the field in which they have worked in improving the total aeronautical science. I believe that their present framework could extend their capability to improving methods in outer space. They have 7,500 employees, many of whom are outstandingly capable and I do believe if their charter were enlarged to special facilities to include outer space, that they would add to our total knowledge. We would have many more capable minds directed to this research.

Mr. WEISL. Well, we do not need legislation to enlarge the work of NACA. Could we not direct the NACA to engage in this work without creating a new agency. At least there you have a board where the majority decide the policy. Here you would have a board which would be the same board initially as the NACA, only that they would not have any vote. They would merely have the right to advise and recommend and be consulted with. Would it not be better to say to NACA, you go ahead and enlarge the scope of your work by conducting research on civilian peaceful uses of outer space without creating a new agency, with a new budget, with new rivalry again for power and jurisdiction? What is your answer?

Mr. JOHNSON. Now you really put me on the spot, sir. Could I defer the answer to that and give it to you in writing at a later date?

Mr. JOHNSON. Yes, sir, I understood. However, in other places in the testimony you will find that I do state we need a civilian agency in space technology.

This question here was directed, as I understood, whether or not we needed to create an agency outside of the NACA framework.

Mr. FELDMAN. I believe what it does say is that if the only thing we are going to do is enlarge the NACA, then why have a new agency? Is that what it boils down to?

Mr. JOHNSON. As I understand, the new agency would absorb the old agency. There would not be a new agency in the sense of another entity.

Mr. FELDMAN. That is not what this question is directed to at all. What he is saying is this, if we simply enlarge NACA you don't have to go to Congress for that, the President might do that by executive order or it might be done through an additional appropriation by the Bureau of the Budget.

Mr. JOHNSON. That is one way to do it, sir, yes, sir.

Mr. FELDMAN. And you would not need the new agency?

Mr. JOHNSON. If you follow that course, yes, sir.

Mr. FELDMAN. How about a space agency directed to the peaceful use of outer space?

Mr. JOHNSON. I believe it would be important in the instruction to the presently existing NACA, in the broadening of its charter, to give the additional authority to explore the science of space rather than to limit themselves to vehicles which the present NACA, as it was set up and as I understand in the language that set it up, did not have

quite the scientific connotation that I think the agency, whatever it should be, should be instructed to participate in. NACA has been primarily concerned with improving aircraft. I think there is a broader connotation required here which is to explore the science of space that would lead to improved transportation in space. To that degree the charter may be broadening.

Mr. FELDMAN. Would the request that you defer the answer to previous questions put to you by Mr. Weisl now be along the lines you have just indicated?

Mr. JOHNSON. Yes, sir. I have not finished the thinking through to answer the question but I do really believe that just to extend NACA would not assure us the peaceful civil scientific exploration that we need. I have gone back and examined the kind of work that NACA has been doing and if they continue to do the same thing but merely extend it to outer space it would be inadequate.

Mr. FELDMAN. Getting back to the previous question concerned with the fact that you were able to see the bill before April 2 and up to the time you testified before this committee, would you say that that would give you ample opportunity to make any suggestions in connection with it to the proper person in the Defense Department? Has that in turn been reconveyed to the people who are concerned with the drafting of this bill to make any corrections that they have?

Mr. JOHNSON. Frankly our problem in the Department of Defense I think was a matter of interpretation of language. As I stated before the Johnson committee, it was only in recent days that people within the Department of Defense became concerned by the language as I was. My discussion up to recent days did not have the impact that it has had recently.

I believe there was the feeling that this language allowed us to continue to work with NACA pretty much as it had in the past and there would be no substantive change.

Mr. FELDMAN. It has been stated, however, that this bill went through the Department of Defense very rapidly and you only had 24 hours to make your comments?

Mr. JOHNSON. That is correct, sir.

Mr. FELDMAN. Did you observe at that time this language in the bill?

Mr. JOHNSON I did, sir, and I so commented in a memo. I made my comments with regard to this controversial clause at that time when it was circulated to the person who was collecting the data who I believe also was a member of the Counsel's office.

Mr. FELDMAN Did you say that you did that by letter?

Mr. JOHNSON Yes.

Mr. FELDMAN. Do you have a copy of that letter here?

Mr. DECHERT I can cast some light on this question if you are willing to let me make a brief statement.

Mr BROOKS Will you make it, sir. We will appreciate it.

Mr. DECHERT I am Robert Dechert, General Counsel in the Department of Defense It is my responsibility to oversee the distribution of proposed pieces of legislation, whether they originate in the Department of Defense or outside, and to ask for comments. This bill has been in the hands of the Department of Defense ever since it was sent to the Congress. I think that the short time that Mr. Feldman mentions was the result of a sudden request we received

to have reports in on the bill, itself, very promptly because the Johnson committee was meeting. Up to that time the bill had been in our hands, but there was no specific request for report to the Congress because we did not know whether it was going to come up in this form or some other form. I ought to say there had been a preliminary discussion of this and there had been a preliminary report to the Bureau of the Budget signed by Mr. Quarles on April 1.

Mr. BROOKS. Do you have those here?

Mr. DECHERT. I don't have the reports themselves. I came rather quickly and gathered the files which were incomplete. The pressure of time, as I say, was pressure of time to get the formal comments in, because it was discovered that these comments would have to be in time for the meeting of the Johnson committee.

As Mr. Roy Johnson indicated, the bill had been available to us, just as you, Mr. Feldman, indicated it was available to Congress.

Mr. FELDMAN. To carry that through further, Mr. Johnson, the witness before this committee was able to see it for that short period of time only because of the fact that you requested——

Mr. DECHERT. No, he had seen it ever since the Congress had seen it. The short time was the time within which to comment.

Mr. FELDMAN. The short time was the time before Congress got it?

Mr. DECHERT. No, sir. This bill reported on to the Bureau of the Budget before it came over here on April 2. It had been seen in a preliminary form; it was reported on.

Mr. FELDMAN. I am addressing myself to that period, not to the time it came over here. I am going back now to before April 2. Isn't that when the 24-hour period took place?

Mr. DECHERT. No, sir; the 24-hour period you are talking about the 24 hours Mr. Roy Johnson appeared before the Johnson committee. I am not sure it is 24 hours.

Mr. JOHNSON. I am sorry, Counselor. There are two 24 hours. The 24 hours I referred to was that for circulation of this within the Pentagon.

Mr. FELDMAN. Can you give us dates while you are talking?

Mr. DECHERT. I can tell you this. It was referred to the Department of Defense by the Bureau of the Budget on Thursday, March 27, and Mr. Quarles made a report for the Department of Defense on Monday, April 1. That is a short period.

Mr. JOHNSON. That is the period I am talking about.

Mr. FELDMAN. So, it was not after April 2; it was before April 2 before the bill came to Congress. It was in that period then that you had only 24 hours within which to make your comments. In fact, it was between March 27 and April 1. Is that not so?

Mr. JOHNSON. There was a 24-hour period. Yes, 24 hours within that period.

Mr. FELDMAN. Did you examine the bill carefully at that time?

Mr. JOHNSON. As carefully as one could under the pressure of business.

Mr. FELDMAN. That was the time you wrote the letter in reporting to Mr. Quarles on the bill?

Mr. JOHNSON. That's right. Well, the letter was addressed to the person soliciting all comments. We have the letter in our file and I wish I had brought it over. I did not realize the line of questioning

here but I am quite sure that comments were asked by counsel's office who was coordinating the comments for Secretary Quarles.

So my letter was undoubtedly addressed to the General Counsel's office.

Mr. FELDMAN. Could we have that letter placed in the record?

Mr. JOHNSON. I will be glad to.

Mr. DECHERT. I am not sure, sir; we will have to consult. This is the kind of thing that is not ordinarily released. It is purely preliminary. In the process of preparing legislation, customarily the great many reports from a great many people are not released because they are purely advisory in nature. It is like comments that committee members would write the chairman if the chairman asked them how to proceed next.

I do not think I can commit the Department of Defense on this, and neither can Mr. Johnson; I can investigate the matter, but I think this is the kind of thing which in the ordinary conduct of business you can't give out, such as comments between members of the Supreme Court before they write their final opinion.

Mr. BROOKS. It merely supports what he says so it should be identical with his testimony.

Mr. DECHERT. It is identical. It was addressed to me, I have seen it. But you can see why this kind of thing, in the nature of things, you cannot give out and still conduct business, because in the case of Mr. Johnson it might be perfectly all right, but another person might make a foolish suggestion. To give out these purely advisory reports might cause people to be unwilling to make any suggestions, because then the report might be brought out in the open.

It may be possible to shorten this whole procedure a good deal. Mr. Johnson has language on the two items that have been mostly under discussion, which language is satisfactory to the executive department as a whole, although it has not finally gone through the ordinary reporting processes.

I cannot commit the whole executive department to this exact language, but I believe confidently it will be approved, having talked to the persons in charge of policy decisions.

Mr. FELDMAN. Is it different from your testimony before this committee when you appeared?

Mr. JOHNSON. Yes, sir.

Mr. FELDMAN. Then I think we should have that language in the record. Would you state it?

Mr. FORD. May I ask, Mr. Chairman, if we have copies of it or will there be copies available?

Mr. BROOKS. We have no copies here.

Mr. DECHERT. It was written in longhand on the way over, after various telephone calls.

It begins on page 2 of the printed bill. I will try not to interrupt again but I will say what was intended. It was intended to carry out what Mr. Quarles said on May 7 before this committee. On the second page of his statement he quoted the statement of policy on page 2, line 4. He actually read a long sentence which begins with the words "The Congress" and ends with the words "in which case the agency may cooperate with, or on behalf of, the Department of Defense."

Then he went on and said in substance that it is "my interpretation of this language that it means that the Department of Defense will be in control of the military aspects." The language Mr. Johnson is about to read is intended to buttress what Mr. Quarles said before your committee on May 7 in this regard.

Mr. JOHNSON. Starting with line 4, lines 4, 5, 6, 7, and 8 remain the same.

Mr. FULTON. On page 2?

Mr. JOHNSON. On page 2. Then beginning line 9, "Operations in the case of which activities"—you can cross out the rest of the sentence that you now have and put new language. This new language is "in the case of which activities the Department of Defense shall be responsible."

Mr. MCDONOUGH. Down to the period on line 10?

Mr. JOHNSON. That is correct. Strike out the whole balance of the sentence.

Mr. BROOKS. Strike out from the word "which" on line 9, the balance of the sentence, which would take you through to the phrase "The Department of Defense" and the period.

Mr. JOHNSON. So then it would read:

> Except insofar as such activities may be peculiar to, or primarily associated with, weapons systems or military operations, in the case of which activity the Department of Defense will be responsible.

Mr. FELDMAN. That leads to this question. What activity, in your opinion, under this language would be of a peaceful nature and over which a new agency devoted to peacetime space research and development would have jurisdiction?

Mr. JOHNSON. Programs that are primarily civil include unmanned space flights to obtain scientific data, such as vertical probes, lunar and interplanetary probes, scientific satellites with associated data acquisition and analysis. I quote from the document that we are working on with NACA.

Mr. FELDMAN. Isn't that as vague as the language in the statute itself?

Mr. JOHNSON. This language must be, I think, vague at this point because we don't know the science out there and what we need to explore.

Mr. FELDMAN. Supposing there is a difference of opinion. Say that you are no longer with ARPA and whoever is at the head of NASA is no longer there and can't agree. What happens?

Mr. JOHNSON. The reconciliation under the terms of the instructions of the President would come to his adviser in the White House. At the moment I would presume he would get his advice from Dr. Killian.

Mr. FELDMAN. Dr. Killian, in turn, would have to make an investigation, a rather detailed investigation, as to the nature of that scientific project; is that not so?

Mr. JOHNSON. That is correct, sir.

Mr. FELDMAN. He would have to have in his employ a staff which would be able to determine that. Isn't that so?

Mr. JOHNSON. That might not necessarily be true. That depends on the capability of the man in that advising spot. If his background were such over a long period of time in this field that he did not need other technical advice he could make that decision personally.

Mr. FELDMAN. He could make the decision; there is no question about that. But, if it was something that involved cosmic rays and he did not know much about that field, could he make that decision then?

Mr. JOHNSON. Obviously not. I think the President would have to have this capability in one or more people to answer your question. It may be more than one.

Mr. FELDMAN. That would be a sort of agency in itself. Is that not so?

Dr. YORK. Am I to testify later or can I interrupt now?

Mr. KEATING. Will it be helpful to have him interrupt at this point?

Mr. FELDMAN. I have no objections to Dr. York answering any questions.

Dr. YORK. The President's adviser on science and technology is also Chairman of the present Science Advisory Committee and on the President's Science Advisory Committee there will always be people who will understand the sort of question you raise. I am a member of that, myself. In fact, I am on the subpanel on space.

Mr. FELDMAN. That is right. So you really have an agency on top of an agency. Is that not so?

Dr. YORK. Well, it is really different from most agencies. I guess that is right.

Mr. KEATING. This Advisory Committee is not in any way an operating agency. It is just a committee which advises the scientific adviser to the President?

Dr. YORK. Yes. It is called the President's Science Advisory Committee.

Mr. BROOKS. Is that set up by statute or by Executive order?

Dr. YORK. By Executive order, I am sure.

Mr. BROOKS. Mr. Johnson, you referred to your recommendation for more representation by the Defense Department. Whom did you recommend for the Defense Department?

Mr. JOHNSON. The language which I understand the Executive is willing to consider is on page 3, line 20, to substitute for "No more than eight," the word "nine" and to include three representatives from the Department of Defense.

Mr. FELDMAN. You say no more than——

Mr. JOHNSON. It says "nine members of the Board shall be designated from appropriate departments."

Mr. FELDMAN. It starts with the word "nine."

Mr. JOHNSON. Yes.

Mr. DECHERT. This is the second of the two things which I can assure you will be agreed to and which Mr. Johnson is glad to have done.

Mr. FULTON. Actually then, on this explanation, there is no contradiction in the testimony before the Johnson committee of the Department of Defense.

Mr. DECHERT. That is right.

Mr. FORD. May I ask how the language would read as now stipulated or proposed?

Mr. DECHERT. On page 3, beginning line 20, you strike our the word "no more than eight" and substitute the single word "nine."

On line 23 you strike out the word "one" and substitute "three." So it reads:

> Nine of the members of the Board shall be designated from appropriate departments or agencies of the Government of the United States, including at least three who shall be from the Department of Defense.

Mr. BROOKS. Members of the Committee, you have heard the second quorum call. What is the pleasure of the committee? I would suggest that we adjourn for 45 minutes and meet back here in 45 minutes.

Mr. MARTIN. If you don't want to come back, use my room 18 for the rest of the afternoon.

(Discussion off the record).

Mr. BROOKS. We will meet in 45 minutes in room 18.

Mr. JOHNSON. We have a mission plane standing by for 4 o'clock departure.

Mr. BROOKS. Can you advise them to make it 5 because it will take us 45 minutes for this rollcall. No question about it.

Mr. KEATING. It is the second call. We might be through in half an hour.

Mr. FULTON. Now that we have cleared up an apparent contradiction, why is it not possible to submit those for the record? Let the counsel submit you the questions.

Mr. FELDMAN. I think I have to get the answers. Let me tell you why. We want to get the record printed as quickly as we can because we are going into executive session tomorrow.

Mr. FORD. Why don't you stay here, George, and ask the questions.

Mr. JOHNSON. That will be better for me.

Mr. BROOKS. The committee will adjourn. In the meantime counsel can ask his questions. I will be right back as soon as I can.

(Brief recess.)

The CHAIRMAN. What was your language before the committee?

Mr. JOHNSON. The language I submitted before the committee, I tried to make clear, was one way to do it. Since that time after consultations through counsel with the Executive Office, I have come to agree to this modification which is acceptable to the Executive Office. This is a change in my position from previous testimony.

The CHAIRMAN. I will not necessarily say a change. Reconciliation probably.

Mr. JOHNSON. Yes, reconciliation would be better.

The CHAIRMAN. You also had some doubts about whether you had the authority to go into research under the language of the bill. What are your views on that now?

Mr. JOHNSON. I believe that research is permissible under this language to the degree that it is associated with military operations and to the degree that we are permitted now to go into research in any other area of science.

The CHAIRMAN. I just wanted to get your views. I remember at the time you were somewhat concerned as to whether the language would permit going into the research part.

Where was the other language that Mr. Johnson suggested?

Mr. FELDMAN. Here it is.

The CHAIRMAN. "In support of" or "presume." We discussed that word "presume" and something along that line was determined. Is that right?

Mr. JOHNSON. That's right.

The CHAIRMAN. Have you made any other suggested amendments to the Senate committee?

Mr. JOHNSON. No, sir. I did not recommend specific language to the Senate committee.

The CHAIRMAN. Have you any other suggested amendments?

Mr. JOHNSON. Yes, sir, on page 3, the designation of the Board, I understand the Executive has agreed also to changing on line 20 "No more than eight" to "nine."

(Discussion off the record.)

Mr. JOHNSON. I do not presume what Secretary McElroy would recommend here but that might not necessarily follow the three services. It could well be that he would recommend the Director of Research and Engineering, the Director of ARPA, and the Air Force.

The CHAIRMAN. I understand. I felt that language of this kind was much more preferred than providing that each one of the services shall be on the Board if they said not less than three.

This language has been cleared by whom?

Mr. JOHNSON. The Executive.

Mr. DECHERT. I have cleared it with the President's office. While it has not been cleared completely through the Government I can assure you that this will go through.

Mr. JOHNSON. Both language changes.

The CHAIRMAN. Any other suggestions?

Mr. JOHNSON. No, sir. Mr. Chairman, at this point in the interrogation regarding these changes I would like to affirmatively state that with these changes this legislation is satisfactory to me.

The CHAIRMAN. That is, the Department of Defense.

Mr. JOHNSON. To me as Director of the Advanced Research Projects Agency.

Mr. DECHERT. I can say it is satisfactory to the Department of Defense as a whole.

The CHAIRMAN. The bill as introduced is what you have addressed yourself to. The one thing that has concerned me is that word "except".

(Discussion off the record.)

The CHAIRMAN. Let me ask your opinion on this language, which has not been acted upon. Nothing has been done by the committee as yet. We are going to sit in executive session tomorrow afternoon:

> The Congress declares that the activities described in paragraph 1 shall be directed by a civilian agency which shall exercise control over aeronautical and space research and development sponsored by the United States and you shall act in full cooperation with (a) the Department of Defense insofar as such activities are peculiar to, or primarily associated with, weapons systems, military operations or the defense of the United States—

this other language can be put in there—

> (b) And the Atomic Energy Commission insofar as such activities * * *

The other language is what relates to the Defense Department. What would be your view?

Dr. YORK. What does that mean? Does that mean that the civilian agency is in charge of the program?

The CHAIRMAN. No (reading):

shall be directed by a civilian agency which shall exercise control over aeronautical and space research and development sponsored by the United States and who shall act in full cooperation with (a) the Department of Defense insofar as such activities are peculiar to or primarily associated with weapons systems.

Dr. YORK. What does that mean? It sounds as though they are in charge but they are supposed to cooperate with us. Space is a place and not a program.

The CHAIRMAN (reading):

In the case of which activities the Department of Defense will be responsible—

assuming that language will be adopted by the committee.

Dr. YORK. You were going to put that language in at the end?

The CHAIRMAN. Yes. I mean, assuming the committee acts on that language. I am assuming that the language is adopted. They say already we are going beyond the language of the original bill introduced along the lines of your proposed amendment made in the public hearings before the committee by adding "or the defense of the United States", which is all embracing.

Mr. JOHNSON. Sir, could that be read again?

The CHAIRMAN (reading):

The Congress declares that the activities described in paragraph 1 shall be directed by a civilian agency which will exercise control over aeronautical and space research and development sponsored by the United States and who shall act in full cooperation with, (a) the Department of Defense insofar as such activities are peculiar to, or primarily associated with, weapons systems, military operations—

then if you add this language, "in the case of which activity the Department of Defense shall be responsible"—assuming that language is added.

Dr. YORK. With that added it makes good sense to me. The point is that space is a place and not a program. In this country I do not think we consider that the ocean belongs to the Maritime Commission and the Navy has to get permission from the Maritime Commission to operate there.

The same way with space, if the Department of Defense wants to put up reconnaisance satellites I don't see why the civilian agency should have anything to say about it. The reconnaisance satellites are for military purposes, they are flying through space and operate in space but it seems to me they are military from start to finish.

Mr. FELDMAN. But you want constant liaison between the two?

Dr. YORK. If the civilian agency has some good ideas, actually in the short run these military programs, in fact both the civil and the military programs are in the Department of Defense. The civil agency has to come to the Department of Defense. All the ideas are in the Department of Defense at the present time.

The CHAIRMAN. How about the international aspect of it?

Dr. YORK. There I think it is easier for the international groups to work with the National Academy or with the civil agency or the Department of Defense.

The CHAIRMAN. What about the State Department?

Dr. YORK. I suppose they have to work through the State Department.

The CHAIRMAN. I can see that there are some programs they may not have to refer to the State Department, but I can see certainly,

where it relates to international and foreign affairs, that it would be unwise if they did not or if we did not provide for it.

Dr. YORK. I think those words you have on this little sheet of paper are awfully important with this rewritten that way.

The CHAIRMAN. Why do you think it is important?

Dr. YORK. If you didn't have those in there, it says the civil agencies are in charge and they are supposed to cooperate with us. It sounds as though if we wanted a reconnaisance satellite we would establish a requirement and then ask them to cooperate by putting one up. Those other words now say they are responsible for the military programs. Without those words then it just says they are supposed to cooperate fully.

Admiral CLARK. Or does it say we are responsible for the cooperation.

The CHAIRMAN. Do you think the language of the bill—"with weapons systems and military operations,"—with this additional language will it cover other activities of the Department of Defense? Are there other activities outside of weapons systems and military operations?

Dr. YORK. There is the research leading to them.

The CHAIRMAN. Are there other tactical activities?

Dr. YORK. What else would there be? We have to cooperate with the Space Agency rather than vice versa because we have all the vehicles.

Mr. DECHERT. May I say a word? I think the Department of Defense and the administration would be entirely ready, and perhaps glad to change the word "should" to "shall"—one of the two suggestions. As to the other, however, if I caught it correctly, you were going to include "or the defense of the United States" as an enlargement of the expression "weapons systems or military operations."

The CHAIRMAN. Some people have been talking about that.

Mr. DECHERT. It is my understanding that the President does not want to go beyond what he said in his message, through fear that if we go beyond, it will look as if we are trying to take this away from civilian control. He has tried to emphasize in the message that this is to be civilian, to the extent it is not directly military. Those words "defense of the United States" are very elastic words. Therefore I believe that the administration wants to keep the expression of the Department of Defense participation in the exact words that the President used on page 4 of his message, which are "weapons systems and military operations."

Mr. Johnson has indicated that the research leading up to weapons system and military operations is necessarily part of those systems and operations themselves.

The CHAIRMAN. I would think so. But on the other hand I suggested to Mr. Johnson that we could put words in there—"do research activities"—or some words to that effect. I thought the authority contained in here carried with it the power to accomplish whatever was necessary. On the other hand, if you wanted it spelled out, I have no objection. You don't like the language, "the defense of the United States."

Mr. DECHERT. I am afraid it is too broad. You remember, before we got into World War II we set up the "Defense Commission", which covered a tremendous territory. As I understand the administration's point of view, there is fear that if we use such very broad words as that,

it will be thrown in our teeth that we are not really setting up a civilian agency, but we are just pretending to do so; we are really giving it all to the military. That result we do not want to bring about.

Admiral CLARK. I should say another objection to it is that what we do in the line of defense here may well be in defense of the free world, not just United States. and we could go further in this program and spell out international cooperation.

The CHAIRMAN. I know, but we could not put in the bill anything in connection with defense of the free world.

Admiral CLARK. No, sir. That is why I say we should leave out any area regarding defense.

Dr. YORK. I thought the words you used were such as to give the NASA more authority over what we were doing rather than less. That is the way it sounded to me without the additional words on that sheet. I thought this was in connection with the authority of the NASA that you were putting them in the defense of the United States.

The CHAIRMAN (reading):

> Insofar as such activities are peculiar to or primarily associated with weapons systems, military operations or the defense.

Well, there may be something to that.

Dr. YORK. It sounded to me as if you were putting the defense space effort into the NASA.

The CHAIRMAN. With this language "In the case of which activities the Department of Defense shall be responsible"——

Dr. YORK. That puts it back to us again.

Mr. JOHNSON. In answer to the question, on thinking it over, I believe the language you are recommending is less clear than the language I am recommending now with the changes I understand the Executive are approving.

Mr. FELDMAN. I don't think there is any less clarity.

Dr. YORK. Does your language allow the Department of Defense to go ahead all on its own and put up reconnaissance and early warning satellites and defend them?

Mr. JOHNSON. This word "cooperate" I am quite sure will be misconstrued to imply that you have the responsibility but cooperate is imperative and there may be situations—there is one right now—with which I don't think a civilian agency could cooperate.

Mr. FELDMAN. Have you attempted to cooperate with a civilian agency?

Mr. JOHNSON. There can be a single military problem that might make cooperation under some circumstances quite difficult, in the broader sense.

The CHAIRMAN. In other words, if this proposed language is in either one of the bills, either one will be satisfactory?

Dr. YORK. Where it says "In which case the Department of Defense will be responsible."

Mr. JOHNSON. If you are asking me the question the answer is "No, sir." The language you are discussing as a possibility for that bill, I think, is less clear than the language which I have recommended to you.

The CHAIRMAN. I say if this language is approved as recommended—

in the case of which activities the Department of Defense shall be responsible * * *.

Mr. FELDMAN. Could I ask a question?

The CHAIRMAN. Certainly.

Mr. FELDMAN. Would you interpret this language you have just suggested as giving you the exclusive authority to decide without any cooperation or without cooperating with the new agency what is military?

Mr. JOHNSON. Yes, sir.

Dr. YORK. Doesn't the House Appropriations Committee decide that when it makes the appropriations?

Mr. FELDMAN. Let us not get into that. We are writing the legislation now. We might as well make the legislation as clear as we can. If you fall under this you can make your own decision as to what is military and what is not——

The CHAIRMAN. We might as well put a bill out and put it in military control.

Mr. DECHERT. Isn't that subject to the fact that both these agencies will be part of the executive department and if those in the civilian agency believed that the military agency had made the wrong decision they always have the right to appeal to the President on it. I think the President is the ultimate arbiter if there is a disagreement.

The CHAIRMAN. I agree with you but Mr. Johnson gave a different answer. Which is it now?

Mr. DECHERT. I think his answer was that the preliminary decision will be the decision of ARPA, but as I say, there must always be an appeal in this kind of thing. Therefore I think Mr. Johnson's answer is properly supplemented by what I say.

The CHAIRMAN. What you said gives us a little different picture than Mr. Johnson's direct answer, which I appreciate. According to his answer, the military has the complete control. We know there will be no difficulty, and as I see it, there should not be. There are certain things which are distinctly military. There might be some things that are peaceful by nature today and years later, when we have a more peaceful world, they might extend themselves further. But there will be some twilight zone decisions to make. It is in that area that these questions arise. According to you there is an honest difference. According to Mr. Johnson the Space Agency could not raise the question.

Mr. DECHERT. I think he did not mean to indicate that. I don't mean to try to read his thoughts. But you asked him pointblank who would make the initial decision. You did not say "initial," but I think that is what he understood. I think that the Department of Defense would make the initial decision that a particular matter is within its jurisdiction, if it believes that it is primarily a military matter.

On the other hand, I think it is clear as long as the statute does not say that the military shall have the final and conclusive view on this that it must necessarily be decided, as other things, are decided within the executive department.

That means in case of disagreement you carry it to the President.

The CHAIRMAN. I can understand that now. Does that represent your views, Mr. Johnson, with this clarification?

Mr. JOHNSON. I agree with counsel completely.

Dr. YORK. Also in the next few years, in fact right now, those definitions will be written out by common law. We are already agreeing with NASA on what they should do and what we should do, what are joint and what should be cooperative. We have four programs—military, civil, joint, and cooperative.

The CHAIRMAN. Following your observation then, there will be no objection if the committee decides to put a provision in the bill providing that where there is a dispute, the President should make the decision.

Mr. DECHERT. If you are asking me alone I think that is all right, and I see no reason why others should not agree with me. That is the practice today.

Dr. YORK. Yes, that is what we are doing right now on the space program.

The CHAIRMAN. The President might designate someone to look into the matter.

Mr. DECHERT. This, sir, is exactly what is being done in another field, the responsibilities in space with respect to use of the airspace by civilian and military airplanes.

The CHAIRMAN. You see, when we are writing a law we have to project our minds into the future as far as we can, to try to see what the law of natural consequences might be in this. No act is final. We know from the past that there has been a clash of personalities and interest, and so forth. I will not go into that because that is human. I found out enough about that in 1954 on the Riehlman committee. I am not saying that in any criticism.

For example, suppose this language was included in the bill:

> If the Department of Defense concludes that any requested action or proposed action or failure to act on the part of the Commission is adverse to the responsibilities of the Department of Defense, or the Commission concludes that any request for action, proposed action or failure to act on the part of the Department of Defense is adverse to the responsibility of the Commission, and the Commission and the Department of Defense are unable to reach agreement with respect thereto, either the Commission or the Secretary of Defense may refer the matter to the President, whose decision shall be final.

Dr. YORK. I would like to get back to this point, that I think the frame of reference that people are thinking in is not quite right, that space is a program and not a place to do certain things. The civil agency is going to have a budget, they are going to ask to do certain things which are approved or not approved and they can go ahead with them according to whether they are approved or not.

The military will also be asked to do certain things in space. It will be approved or disapproved. It can go ahead with what is approved for it and the civilian agency will go ahead with what is approved for it. We are doing the things which will mainly support defense. The civilian agency will have a budget of a certain size. They will do things which mainly support the civil space program. If we both do something there might be a small amount of duplication but those are the kinds of things that we iron out in a liaison committee.

I don't know why one should be so careful in dividing up the program. We will both operate in space but we will not run into each other or these satellites are not going to collide. There is plenty of room up there for both programs. What we want to do is recon-

naissance, early warning. We want to investigate man in space. So does the civilian agency. We are going to do that jointly.

The CHAIRMAN. I think you should do it jointly. I just read some language. What is your objection to that?

Mr. DECHERT. Mr. Johnson has said as far as he is concerned that seems appropriate and I for the Department of Defense as a whole say that the procedure is appropriate.

I cannot speak beyond that general statement. I will be glad to investigate it.

It seems to me the procedure we now adopt in many fields is perfectly natural.

The CHAIRMAN. I think we have cleared the air a lot.

Mr. MARTIN. All intents are the same.

The CHAIRMAN. Everyone on this committee is a practical man. We realize what the world is, we know what the dangers are, and we know what the situation is. We recognize the urgency of defense, not as a national objective but rather the necessity of defense while other national objectives of an affirmative nature are pursued. We try to bring them into effect as far as possible, such as disarmament.

Mr. FELDMAN. I want to call Mr. Johnson's attention to his testimony before the Senate committee in which he said that "both civilian and military agencies should be permitted to go their independent roads if they so desire."

Is that view consistent with your statement?

Is that view consistent with the statement to the Senate committee that "this Nation cannot afford the luxury of duplication in space research"?

Mr. JOHNSON. To answer that question I do not believe that you would necessarily have duplication by allowing both agencies to go independent routes. I think you would have parallel work at worst, and I did say in my statement to one of these committees that I did not think the scientific work very often was duplicated.

Scientists do not like to go down identical paths of another scientist.

Mr. FELDMAN. We are not talking of scientific work exclusively now. But when you say that you see no harm in parallel work, it could be in duplication when it is parallel. Is that not so?

Mr. JOHNSON. It could be under certain circumstances; yes. I think you could say there is some duplication in aircraft design between the military airplane design and the civilian airplane design.

Mr. MARTIN. It is not likely to be very large with the Appropriations Committee supervising the expenditure.

Dr. YORK. If there are responsible people in the agencies, if there is cosmic-ray data available that is of use in the space program, we are going to be husbanding our resources and not duplicate that research.

Mr. FELDMAN. That will be accomplished through constant liaison. Is that not so?

Dr. YORK. Yes. I do think some programs will be so expensive that they ought to be joint. We are already planning to do that. The "man-in-space" program will cost a lot of money.

Mr. JOHNSON. Before you came to this meeting, Mr. Chairman, I discussed the document that we are now ready to submit for approval to the Secretary of Defense and the Chairman of the National Advisory Committee for Aeronautics which spells out in detail this

working relationship to provide minimum duplication between the two agencies.

We are in complete agreement for 1959 on what to do and how to do it.

(Discussion off the record.)

Mr. FELDMAN. Should not some person or agency plan and coordinate all aspects of space research in order to prevent gaps and to insure effective cooperation?

Mr. JOHNSON. Definitely not, sir. I think that would be the most tragic thing that could happen to this country.

Dr. YORK. You do not do that with maritime. The maritime and Navy go on and both use the ocean.

Mr. FELDMAN. What I am thinking of is what happened at Pearl Harbor where the Army and the Navy were supposed to act in cooperation with each other and they did not. I suppose they did get together there but there was no requirement that they do that at all. The result was that when the Army got the information about the Japanese planes coming there was no one to give it to the Navy.

Dr. YORK. Of course, the purpose of ARPA is to make sure that the Army, Navy, and Air Force are together on the space program.

Mr. FELDMAN. Why not the civilian agency? Why not have the same cooperation with them?

Dr. YORK. If their purpose is primarily to explore space and planets, and so on, all we need is the information they get. If they are not getting the information that is necessary for defense we get it ourselves. That is why I think these things can be almost independent.

Mr. FELDMAN. They can be almost independent and then we will run into another Pearl Harbor.

Dr. YORK. I don't see how there could be another Pearl Harbor in a case like this.

Mr. FELDMAN. I am talking of organization now. We know this, that the Atomic Energy Commission has problems with the military; they have constant liaison, and problems are ironed out. How many of these difficulties do get to the President at all when there is a dispute between them as to what is military and what belongs to the Atomic Energy Commission? If you look into the history of AEC, practically nothing has been referred to the President. The reason is that there is constant liaison. The right hand knows what the left hand is doing constantly.

Dr. YORK. We are back on the liaison question. We already are having plenty of liaison. We meet with NACA almost every day.

Mr. FELDMAN. Supposing your successor decides not to do that.

Dr. YORK. He would be acting irresponsibly.

Mr. JOHNSON. Sir, may I interject here? Does this question imply that you would set up one commission to rule all space 1 inch above the ground and coordinate all production of all aircraft, civil and military, and all transport and all travel in air, wherever it is?

Mr. FELDMAN. I am not setting forth what the agency will do. I am trying to get enough information of what it should do.

Mr. JOHNSON. I am trying to understand what your language meant.

Mr. FELDMAN. What language?

Mr. JOHNSON. The question you just asked us for the record here.

Mr. FELDMAN. I am just trying to get your views on what kind of

cooperation we should have. You say that each agency should be independent. At least Dr. York says that.

Dr. YORK. Yes.

Mr. FELDMAN. And whether or not they will have liaison between them will be a matter of discretion.

Dr. YORK. I did not want to get mixed up in the argument about liaison. I think liaison is fine whether it is in the law or not.

Mr. FELDMAN. It is all part of the same ball of wax.

Dr. YORK. Right. What is worrying me is if this liaison committee was made independent of the two organizations and sort of sitting above them.

Mr. FELDMAN. How does the liaison committee in the Atomic Energy Commission function with the military?

Dr. YORK. It is not above the Department of Defense or the Atomic Energy Commission. It is a channel of information. That kind of liaison committee I am all for.

Mr. MARTIN. I understand these gentlemen have a very important conference at 4 o'clock. Is that true?

Mr. JOHNSON. We have a military mission to fly to Cambridge at 4 o'clock today with some 15 or 20 men.

Mr. FELDMAN. I just want to ask one more question. In other words, when the President now is talking of a national space program—National Space Agency—what you are saying instead is that we should have one for the Department of Defense and one for peacetime.

Dr. YORK. I say space is a place and not a program at all. It is a place where you have different programs.

Mr. FELDMAN. Then the President's message does not mean what it says, in other words.

Mr. BROOKS. Mr. Johnson, on page 3 you refer to the membership of the Board—National Aeronautics and Space Board. That will come up further in the bill any number of times. I have done a good deal of work with the Reserves and I was wondering if you would classify a reservist on inactive duty as a member of the Government, a civilian or a civilian member of the Defense Department?

If that is the case, then the question of emolument comes in. I think he is civilian unless he is on active duty. I think that ought to be cleared up. If the President should appoint a member of the Reserve establishment just because he has a commission in the Reserves, it would not make many ineligible or not make many a representative of the Defense Department.

Mr. JOHNSON. I think that is correct, sir.

The CHAIRMAN. You say this language has been cleared in the executive branch?

Mr. DECHERT. Yes, sir.

The CHAIRMAN. Who?

Mr. DECHERT. Mr. Gerald Morgan, counsel to the President.

The CHAIRMAN. "Nine members of the Board shall be designated." That shifts it from the 8 to the 9.

Mr. DECHERT. The previous draft says "not more than eight." This now has nine.

Mr. FELDMAN. Thus, he could have one for that matter because it said not more than eight. Now this clarifies that.

Mr. BROOKS. That makes a very important change. It creates Government control.

Mr. JOHNSON. That is right.

The CHAIRMAN. Who passed on that?

Mr. DECHERT. Mr. Morgan. Mr. Johnson explained that it might be civilians from the Department of Defense. It says at least three. It could be more than three.

Mr. BROOKS. It would not be a Reserve officer?

Mr. DECHERT. I think this matter of Reserve officer is covered by the statutes.

The CHAIRMAN. You still keep "the Chairman of the Board shall be designated by the Department from among the civilians."

Mr. DECHERT. There is no change in that.

The CHAIRMAN. What caused the change from "eight" to "nine"?

Mr. JOHNSON. This is a Government agency, it will therefore have a majority vote by Government representatives.

Mr. FELDMAN. Was it not also because of the fact that that point was stressed before the Senate committee?

Mr. JOHNSON. I think that has been discussed there, too; yes, sir.

Mr. FELDMAN. When you say "disputes should be resolved by the President", you really mean the Presidency, is that not so?

Mr. JOHNSON. The Executive Office; yes.

Mr. FELDMAN. Won't the decisions be made in practice by some lower echelon, perhaps by the Bureau of the Budget?

Mr. JOHNSON. The Bureau of the Budget is a member of the Executive Office. He could indicate that the Bureau of the Budget could make the decision for him.

The CHAIRMAN. Any further questions?

Mr. BROOKS. Mr. Johnson, are you going to put a copy of your agreed arrangement in the record? Is it available for this record? I mean that which you have in your hand now.

Mr. JOHNSON. This document?

Mr. BROOKS. Yes.

Mr. JOHNSON. When this document has been approved and signed by the Secretary of Defense and Chairman of the National Advisory Committee for Aeronautics I shall be very glad to have this as part of the record. I cannot now because it has not been approved yet. This is a working paper.

Mr. FELDMAN. I have one further question, Dr. York. Getting back to that point about you having only 24 hours within which to look at the President's bill, isn't it a fact that you are a member of the National Advisory Committee?

Dr. YORK. The President's Science Advisory Committee.

Mr. FELDMAN. That is the Killian committee; is that not so?

Dr. YORK. Yes.

Mr. FELDMAN. Weren't you apprised of the bill before?

Dr. YORK. I saw a number of versions of it as it went along; yes; but that was before I was in the Defense Department. After I went over there I had the same situation as Mr. Johnson, namely, that I did not see the final version of the bill when it came over until he saw it. I did see working papers as we went along.

Mr. FELDMAN. How much time did you spend in connection with the bill?

Dr. YORK. I saw various and sundry working papers on it, I would say, off and on for about a month before it came over to the Department of Defense.

Mr. FELDMAN. So that it was not new to you, in other words?

Dr. YORK. No; it was not new, although this particular version was new.

Mr. FELDMAN. Do you mean the final bill as it was sent to you?

Dr. YORK. Yes; the one that came over about the 27th of March.

Mr. FELDMAN. But you had seen the bill grow?

Dr. YORK. I had seen it grow.

Mr. FELDMAN. Would you say that it went through your Department at least on a motorcycle?

Mr. YORK. You mean in the Killian committee?

Mr. FELDMAN. Yes.

Mr. YORK. No, I don't think it went through on a motorcycle. It was in and out of the office for something like a month. As I say, these were working papers with lots of different versions. It was not until it came over to the Department of Defense that I knew which one of the many possible versions it was finally going to be. On the other hand it was no surprise to me that NASA was to be built on NACA.

I sat in on many of the arguments about whether or not the Director should report to the President and all that sort of thing.

The CHAIRMAN. Any further questions?

Thank you very much, gentlemen. We will make this a part of the public record.

(Whereupon, at 3:55 p. m., Monday, May 12, 1958, the committee adjourned, subject to the call of the Chair.)
